so the automorphism $\lambda \mapsto \bar{\lambda}$ is the identity. \square

The definition of the linear maps l_φ and r_φ requires a small twist due to the automorphism $\lambda \mapsto \bar{\lambda}$.

Definition 29.9. Given a vector space E over a field K with an involutive automorphism $\lambda \mapsto \bar{\lambda}$, we define the K -vector space \bar{E} as E with its abelian group structure, but with scalar multiplication given by

$$(\lambda, u) \mapsto \bar{\lambda}u.$$

Given two K -vector spaces E and F , a *semilinear map* $f: E \rightarrow F$ is a function, such that for all $u, v \in E$, for all $\lambda \in K$, we have

$$\begin{aligned} f(u + v) &= f(u) + f(v) \\ f(\lambda u) &= \bar{\lambda}f(u). \end{aligned}$$

Because $\bar{\bar{\lambda}} = \lambda$, observe that a function $f: E \rightarrow F$ is semilinear iff it is a linear map $f: \bar{E} \rightarrow F$. The K -vector spaces E and \bar{E} are isomorphic, since any basis $(e_i)_{i \in I}$ of E is also a basis of \bar{E} .

The maps l_φ and r_φ are defined as follows:

For every $u \in E$, let $l_\varphi(u)$ be the linear form in F^* defined so that

$$l_\varphi(u)(y) = \overline{\varphi(u, y)} \quad \text{for all } y \in F,$$

and for every $v \in F$, let $r_\varphi(v)$ be the linear form in E^* defined so that

$$r_\varphi(v)(x) = \varphi(x, v) \quad \text{for all } x \in E.$$

The reader should check that because we used $\overline{\varphi(u, y)}$ in the definition of $l_\varphi(u)(y)$, the function $l_\varphi(u)$ is indeed a linear form in F^* . It is also easy to check that l_φ is a linear map $l_\varphi: \bar{E} \rightarrow F^*$, and that r_φ is a linear map $r_\varphi: \bar{F} \rightarrow E^*$ (equivalently, $l_\varphi: E \rightarrow F^*$ and $r_\varphi: F \rightarrow E^*$ are semilinear).

The notion of a nondegenerate sesquilinear form is identical to the notion for bilinear forms. For the convenience of the reader, we repeat the definition.

Definition 29.10. A sesquilinear map $\varphi: E \times F \rightarrow K$ is said to be *nondegenerate* iff the following conditions hold:

- (1) For every $u \in E$, if $\varphi(u, v) = 0$ for all $v \in F$, then $u = 0$, and
- (2) For every $v \in F$, if $\varphi(u, v) = 0$ for all $u \in E$, then $v = 0$.

Proposition 29.1 translates into the following proposition. The proof is left as an exercise.

Proposition 29.9. *Given a sesquilinear map $\varphi: E \times F \rightarrow K$, the following properties hold:*

- (a) *The map l_φ is injective iff Property (1) of Definition 29.10 holds.*
- (b) *The map r_φ is injective iff Property (2) of Definition 29.10 holds.*
- (c) *The sesquilinear form φ is nondegenerate and iff l_φ and r_φ are injective.*
- (d) *If the sesquilinear form φ is nondegenerate and if E and F have finite dimensions, then $\dim(E) = \dim(F)$, and $l_\varphi: \overline{E} \rightarrow F^*$ and $r_\varphi: \overline{F} \rightarrow E^*$ are linear isomorphisms.*

Propositions 29.2 and 29.3 also generalize to sesquilinear forms. We also have the following version of Theorem 29.4, whose proof is left as an exercise.

Theorem 29.10. *Given any sesquilinear form $\varphi: E \times E \rightarrow K$ with $\dim(E) = n$, if φ is Hermitian and K does not have characteristic 2, then there is a basis (e_1, \dots, e_n) of E such that $\varphi(e_i, e_j) = 0$, for all $i \neq j$.*

As in Section 29.1, if E and F are finite-dimensional vector spaces and if (e_1, \dots, e_m) is a basis of E and (f_1, \dots, f_n) is a basis of F then the sesquilinearity of φ yields

$$\varphi\left(\sum_{i=1}^m x_i e_i, \sum_{j=1}^n y_j f_j\right) = \sum_{i=1}^m \sum_{j=1}^n x_i \varphi(e_i, f_j) \bar{y}_j.$$

This shows that φ is completely determined by the $n \times m$ matrix $M = (m_{ij})$ with $m_{ij} = \varphi(e_j, f_i)$, and in matrix form, we have

$$\varphi(x, y) = x^\top M^\top \bar{y} = y^* M x,$$

where x and \bar{y} are the column vectors associated with $(x_1, \dots, x_m) \in K^m$ and $(\bar{y}_1, \dots, \bar{y}_n) \in K^n$, and $y^* = \bar{y}^\top$. As earlier, we are committing the slight abuse of notation of letting x denote both the vector $x = \sum_{i=1}^m x_i e_i$ and the column vector associated with (x_1, \dots, x_n) (and similarly for y).

Definition 29.11. If (e_1, \dots, e_m) is a basis of E and (f_1, \dots, f_n) is a basis of F , for any sesquilinear form $\varphi: E \times F \rightarrow K$, the $n \times m$ matrix $M = (m_{ij})$ given by $m_{ij} = \varphi(e_j, f_i)$ for $i = 1, \dots, n$ and $j = 1, \dots, m$ is called the *matrix of φ with respect to the bases (e_1, \dots, e_m) and (f_1, \dots, f_n)* .

Proposition 29.5 also holds for sesquilinear forms and their matrix representations.

Observe that if φ is a Hermitian form ($E = F$) and if K does not have characteristic 2, then by Theorem 29.10, there is a basis of E with respect to which the matrix M representing φ is a diagonal matrix. If $K = \mathbb{C}$, then these entries are real, and this allows us to classify completely the Hermitian forms.

Proposition 29.11. *Given any Hermitian form $\varphi: E \times E \rightarrow \mathbb{C}$ with $\dim(E) = n$, there is a basis (e_1, \dots, e_n) of E such that*

$$\Phi\left(\sum_{i=1}^n x_i e_i\right) = \sum_{i=1}^p x_i^2 - \sum_{i=p+1}^{p+q} x_i^2,$$

with $0 \leq p, q$ and $p + q \leq n$.

The proof of Proposition 29.11 is the same as the real case of Proposition 29.6. Sylvester's inertia law (Proposition 29.7) also holds for Hermitian forms: p and q only depend on φ .

29.3 Orthogonality

In this section we assume that we are dealing with a sesquilinear form $\varphi: E \times F \rightarrow K$. We allow the automorphism $\lambda \mapsto \bar{\lambda}$ to be the identity, in which case φ is a bilinear form. This way, we can deal with properties shared by bilinear forms and sesquilinear forms in a uniform fashion. Orthogonality is such a property.

Definition 29.12. Given a sesquilinear form $\varphi: E \times F \rightarrow K$, we say that two vectors $u \in E$ and $v \in F$ are *orthogonal* (or *conjugate*) if $\varphi(u, v) = 0$. Two subsets $E' \subseteq E$ and $F' \subseteq F$ are *orthogonal* if $\varphi(u, v) = 0$ for all $u \in E'$ and all $v \in F'$. Given a subspace U of E , the *right orthogonal space* of U , denoted U^\perp , is the subspace of F given by

$$U^\perp = \{v \in F \mid \varphi(u, v) = 0 \text{ for all } u \in U\},$$

and given a subspace V of F , the *left orthogonal space* of V , denoted V^\perp , is the subspace of E given by

$$V^\perp = \{u \in E \mid \varphi(u, v) = 0 \text{ for all } v \in V\}.$$

When E and F are distinct, there is little chance of confusing the right orthogonal subspace U^\perp of a subspace U of E and the left orthogonal subspace V^\perp of a subspace V of F . However, if $E = F$, then $\varphi(u, v) = 0$ does not necessarily imply that $\varphi(v, u) = 0$, that is, orthogonality is not necessarily symmetric. Thus, if both U and V are subsets of E , there is a notational ambiguity if $U = V$. In this case, we may write U^{\perp_r} for the right orthogonal and U^{\perp_l} for the left orthogonal.

The above discussion brings up the following point: When is orthogonality symmetric?

If φ is bilinear, it is shown in E. Artin [6] (and in Jacobson [98]) that orthogonality is symmetric iff either φ is symmetric or φ is alternating ($\varphi(u, u) = 0$ for all $u \in E$).

If φ is sesquilinear, the answer is more complicated. In addition to the previous two cases, there is a third possibility:

$$\varphi(u, v) = \epsilon \overline{\varphi(v, u)} \quad \text{for all } u, v \in E,$$

where ϵ is some nonzero element in K . We say that φ is ϵ -Hermitian. Observe that

$$\varphi(u, u) = \epsilon \overline{\epsilon} \varphi(u, u),$$

so if φ is not alternating, then $\varphi(u, u) \neq 0$ for some u , and we must have $\epsilon \overline{\epsilon} = 1$. The most common cases are

1. $\epsilon = 1$, in which case φ is *Hermitian*, and
2. $\epsilon = -1$, in which case φ is *skew-Hermitian*.

If φ is alternating and K is not of characteristic 2, then equation (*) from Section 29.2 implies that the automorphism $\lambda \mapsto \bar{\lambda}$ must be the identity if φ is nonzero. If so, φ is skew-symmetric, so $\epsilon = -1$.

In summary, if φ is either symmetric, alternating, or ϵ -Hermitian, then orthogonality is symmetric, and it makes sense to talk about *the* orthogonal subspace U^\perp of U .

Observe that if φ is ϵ -Hermitian, then

$$r_\varphi = \epsilon l_\varphi.$$

This is because

$$\begin{aligned} l_\varphi(u)(y) &= \overline{\varphi(u, y)} \\ r_\varphi(u)(y) &= \varphi(y, u) \\ &= \epsilon \overline{\varphi(u, y)}, \end{aligned}$$

so $r_\varphi = \epsilon l_\varphi$.

If E and F are finite-dimensional with bases (e_1, \dots, e_m) and (f_1, \dots, f_n) , and if φ is represented by the $n \times m$ matrix M , then φ is ϵ -Hermitian iff

$$M = \epsilon M^*,$$

where $M^* = (\overline{M})^\top$ (as usual). This captures the following kinds of familiar matrices:

1. Symmetric matrices ($\epsilon = 1$)
2. Skew-symmetric matrices ($\epsilon = -1$)

- 3. Hermitian matrices ($\epsilon = 1$)
- 4. Skew-Hermitian matrices ($\epsilon = -1$).

Going back to a sesquilinear form $\varphi: E \times F \rightarrow K$, for any subspace U of E , it is easy to check that

$$U \subseteq (U^\perp)^\perp,$$

and that for any subspace V of F , we have

$$V \subseteq (V^\perp)^\perp.$$

For simplicity of notation, we write $U^{\perp\perp}$ instead of $(U^\perp)^\perp$ (and $V^{\perp\perp}$ instead of $(V^\perp)^\perp$).

Given any two subspaces U_1 and U_2 of E , if $U_1 \subseteq U_2$, then $U_2^\perp \subseteq U_1^\perp$. Indeed, if $v \in U_2^\perp$ then $\varphi(u_2, v) = 0$ for all $u_2 \in U_2$, and since $U_1 \subseteq U_2$ this implies that $\varphi(u_1, v) = 0$ for all $u_1 \in U_1$, which shows that $v \in U_1^\perp$. Similarly for any two subspaces V_1, V_2 of F , if $V_1 \subseteq V_2$, then $V_2^\perp \subseteq V_1^\perp$. As a consequence,

$$U^\perp = U^{\perp\perp\perp}, \quad V^\perp = V^{\perp\perp\perp}.$$

First, we have $U^\perp \subseteq U^{\perp\perp\perp}$. Second, from $U \subseteq U^\perp$, we get $U^{\perp\perp\perp} \subseteq U^\perp$, so $U^\perp = U^{\perp\perp\perp}$. The other equation is proved in a similar way.

Observe that φ is nondegenerate iff $E^\perp = \{0\}$ and $F^\perp = \{0\}$. Furthermore, since

$$\begin{aligned} \varphi(u + x, v) &= \varphi(u, v) \\ \varphi(u, v + y) &= \varphi(u, v) \end{aligned}$$

for any $x \in F^\perp$ and any $y \in E^\perp$, we see that we obtain by passing to the quotient a sesquilinear form

$$[\varphi]: (E/F^\perp) \times (F/E^\perp) \rightarrow K$$

which is nondegenerate.

Proposition 29.12. *For any sesquilinear form $\varphi: E \times F \rightarrow K$, the space E/F^\perp is finite-dimensional iff the space F/E^\perp is finite-dimensional; if so, $\dim(E/F^\perp) = \dim(F/E^\perp)$.*

Proof. Since the sesquilinear form $[\varphi]: (E/F^\perp) \times (F/E^\perp) \rightarrow K$ is nondegenerate, the maps $l_{[\varphi]}: \overline{(E/F^\perp)} \rightarrow (F/E^\perp)^*$ and $r_{[\varphi]}: \overline{(F/E^\perp)} \rightarrow (E/F^\perp)^*$ are injective. If $\dim(E/F^\perp) = m$, then $\dim(E/F^\perp) = \dim((E/F^\perp)^*)$, so by injectivity of $r_{[\varphi]}$, we have $\dim(F/E^\perp) = \dim(\overline{(F/E^\perp)}) \leq m$. A similar reasoning using the injectivity of $l_{[\varphi]}$ applies if $\dim(F/E^\perp) = n$, and we get $\dim(E/F^\perp) = \dim(\overline{(E/F^\perp)}) \leq n$. Therefore, $\dim(E/F^\perp) = m$ is finite iff $\dim(F/E^\perp) = n$ is finite, in which case $m = n$ by Proposition 29.1(d). \square

If U is a subspace of a space E , recall that the *codimension* of U is the dimension of E/U , which is also equal to the dimension of any subspace V such that E is a direct sum of U and V ($E = U \oplus V$).

Proposition 29.12 implies the following useful fact.

Proposition 29.13. *Let $\varphi: E \times F \rightarrow K$ be any nondegenerate sesquilinear form. A subspace U of E has finite dimension iff U^\perp has finite codimension in F . If $\dim(U)$ is finite, then $\text{codim}(U^\perp) = \dim(U)$, and $U^{\perp\perp} = U$.*

Proof. Since φ is nondegenerate $E^\perp = \{0\}$ and $F^\perp = \{0\}$, so Proposition 29.12 applied to the restriction of φ to $U \times F$ implies that a subspace U of E has finite dimension iff U^\perp has finite codimension in F , and that if $\dim(U)$ is finite, then $\text{codim}(U^\perp) = \dim(U)$. Since U^\perp and $U^{\perp\perp}$ are orthogonal, and since $\text{codim}(U^\perp)$ is finite, $\dim(U^{\perp\perp})$ is finite and we have $\dim(U^{\perp\perp}) = \text{codim}(U^{\perp\perp}) = \text{codim}(U^\perp) = \dim(U)$. Since $U \subseteq U^{\perp\perp}$, we must have $U = U^{\perp\perp}$. \square

Proposition 29.14. *Let $\varphi: E \times F \rightarrow K$ be any sesquilinear form. Given any two subspaces U and V of E , we have*

$$(U + V)^\perp = U^\perp \cap V^\perp.$$

Furthermore, if φ is nondegenerate and if U and V are finite-dimensional, then

$$(U \cap V)^\perp = U^\perp + V^\perp.$$

Proof. If $w \in (U + V)^\perp$, then $\varphi(u + v, w) = 0$ for all $u \in U$ and all $v \in V$. In particular, with $v = 0$, we have $\varphi(u, w) = 0$ for all $u \in U$, and with $u = 0$, we have $\varphi(v, w) = 0$ for all $v \in V$, so $w \in U^\perp \cap V^\perp$. Conversely, if $w \in U^\perp \cap V^\perp$, then $\varphi(u, w) = 0$ for all $u \in U$ and $\varphi(v, w) = 0$ for all $v \in V$. By bilinearity, $\varphi(u + v, w) = \varphi(u, w) + \varphi(v, w) = 0$, which shows that $w \in (U + V)^\perp$. Therefore, the first identity holds.

Now, assume that φ is nondegenerate and that U and V are finite-dimensional, and let $W = U^\perp + V^\perp$. Using the equation that we just established and the fact that U and V are finite-dimensional, by Proposition 29.13, we get

$$W^\perp = U^{\perp\perp} \cap V^{\perp\perp} = U \cap V.$$

We can apply Proposition 29.12 to the restriction of φ to $U \times W$ (since $U^\perp \subseteq W$ and $W^\perp \subseteq U$), and we get

$$\dim(U/W^\perp) = \dim(U/(U \cap V)) = \dim(W/U^\perp).$$

If T is a supplement of U^\perp in W so that $W = U^\perp \oplus T$ and if S is a supplement of W in E so that $E = W \oplus S$, then $\text{codim}(W) = \dim(S)$, $\dim(T) = \dim(W/U^\perp)$, and we have the direct sum

$$E = U^\perp \oplus T \oplus S$$

which implies that

$$\dim(T) = \text{codim}(U^\perp) - \dim(S) = \text{codim}(U^\perp) - \text{codim}(W)$$

so

$$\dim(U/(U \cap V)) = \dim(W/U^\perp) = \text{codim}(U^\perp) - \text{codim}(W),$$

and since $\text{codim}(U^\perp) = \dim(U)$, we deduce that

$$\dim(U \cap V) = \text{codim}(W).$$

However, by Proposition 29.13, we have $\dim(U \cap V) = \text{codim}((U \cap V)^\perp)$, so $\text{codim}(W) = \text{codim}((U \cap V)^\perp)$, and since $W \subseteq W^{\perp\perp} = (U \cap V)^\perp$, we must have $W = (U \cap V)^\perp$, as claimed. \square

In view of Proposition 29.12, we can make the following definition.

Definition 29.13. Let $\varphi: E \times F \rightarrow K$ be any sesquilinear form. If E/F^\perp and F/E^\perp are finite-dimensional, then their common dimension is called the *rank* of the form φ . If E/F^\perp and F/E^\perp have infinite dimension, we say that φ has infinite rank.

Not surprisingly, the rank of φ is related to the ranks of l_φ and r_φ .

Proposition 29.15. *Let $\varphi: E \times F \rightarrow K$ be any sesquilinear form. If φ has finite rank r , then l_φ and r_φ have the same rank, which is equal to r .*

Proof. Because for every $u \in E$,

$$l_\varphi(u)(y) = \overline{\varphi(u, y)} \quad \text{for all } y \in F,$$

and for every $v \in F$,

$$r_\varphi(v)(x) = \varphi(x, v) \quad \text{for all } x \in E,$$

it is clear that the kernel of $l_\varphi: \overline{E} \rightarrow F^*$ is equal to F^\perp and that, the kernel of $r_\varphi: \overline{F} \rightarrow E^*$ is equal to E^\perp . Therefore, $\text{rank}(l_\varphi) = \dim(\text{Im } l_\varphi) = \dim(E/F^\perp) = r$, and similarly $\text{rank}(r_\varphi) = \dim(F/E^\perp) = r$. \square

Remark: If the sesquilinear form φ is represented by the matrix $n \times m$ matrix M with respect to the bases (e_1, \dots, e_m) in E and (f_1, \dots, f_n) in F , it can be shown that the matrix representing l_φ with respect to the bases (e_1, \dots, e_m) and (f_1^*, \dots, f_n^*) is \overline{M} , and that the matrix representing r_φ with respect to the bases (f_1, \dots, f_n) and (e_1^*, \dots, e_m^*) is M^\top . It follows that the rank of φ is equal to the rank of M .

29.4 Adjoint of a Linear Map

Let E_1 and E_2 be two K -vector spaces, and let $\varphi_1: E_1 \times E_1 \rightarrow K$ be a sesquilinear form on E_1 and $\varphi_2: E_2 \times E_2 \rightarrow K$ be a sesquilinear form on E_2 . It is also possible to deal with the more general situation where we have four vector spaces E_1, F_1, E_2, F_2 and two sesquilinear forms $\varphi_1: E_1 \times F_1 \rightarrow K$ and $\varphi_2: E_2 \times F_2 \rightarrow K$, but we will leave this generalization as an exercise. We also assume that l_{φ_1} and r_{φ_1} are bijective, which implies that φ_1 is nondegenerate. This is automatic if the space E_1 is finite dimensional and φ_1 is nondegenerate.

Given any linear map $f: E_1 \rightarrow E_2$, for any fixed $u \in E_2$, we can consider the linear form in E_1^* given by

$$x \mapsto \varphi_2(f(x), u), \quad x \in E_1.$$

Since $r_{\varphi_1}: \overline{E_1} \rightarrow E_1^*$ is bijective, there is a unique $y \in E_1$ (because the vector spaces E_1 and $\overline{E_1}$ only differ by scalar multiplication), so that

$$\varphi_2(f(x), u) = \varphi_1(x, y), \quad \text{for all } x \in E_1.$$

If we denote this unique $y \in E_1$ by $f^{*l}(u)$, then we have

$$\varphi_2(f(x), u) = \varphi_1(x, f^{*l}(u)), \quad \text{for all } x \in E_1, \text{ and all } u \in E_2.$$

Thus, we get a function $f^{*l}: E_2 \rightarrow E_1$. We claim that this function is a linear map. For any $v_1, v_2 \in E_2$, we have

$$\begin{aligned} \varphi_2(f(x), v_1 + v_2) &= \varphi_2(f(x), v_1) + \varphi_2(f(x), v_2) \\ &= \varphi_1(x, f^{*l}(v_1)) + \varphi_1(x, f^{*l}(v_2)) \\ &= \varphi_1(x, f^{*l}(v_1) + f^{*l}(v_2)) \\ &= \varphi_1(x, f^{*l}(v_1 + v_2)), \end{aligned}$$

for all $x \in E_1$. Since r_{φ_1} is injective, we conclude that

$$f^{*l}(v_1 + v_2) = f^{*l}(v_1) + f^{*l}(v_2).$$

For any $\lambda \in K$, we have

$$\begin{aligned} \varphi_2(f(x), \lambda v) &= \overline{\lambda} \varphi_2(f(x), v) \\ &= \overline{\lambda} \varphi_1(x, f^{*l}(v)) \\ &= \varphi_1(x, \lambda f^{*l}(v)) \\ &= \varphi_1(x, f^{*l}(\lambda v)), \end{aligned}$$

for all $x \in E_1$. Since r_{φ_1} is injective, we conclude that

$$f^{*l}(\lambda v) = \lambda f^{*l}(v).$$

Therefore, f^{*l} is linear. We call it the *left adjoint* of f .

Now, for any fixed $u \in E_2$, we can consider the linear form in E_1^* given by

$$x \mapsto \overline{\varphi_2(u, f(x))} \quad x \in E_1.$$

Since $l_{\varphi_1}: \overline{E_1} \rightarrow E_1^*$ is bijective, there is a unique $y \in E_1$ so that

$$\overline{\varphi_2(u, f(x))} = \overline{\varphi_1(y, x)}, \quad \text{for all } x \in E_1.$$

If we denote this unique $y \in E_1$ by $f^{*r}(u)$, then we have

$$\varphi_2(u, f(x)) = \varphi_1(f^{*r}(u), x), \quad \text{for all } x \in E_1, \text{ and all } u \in E_2.$$

Thus, we get a function $f^{*r}: E_2 \rightarrow E_1$. As in the previous situation, it is easy to check that f^{*r} is linear. We call it the *right adjoint* of f . In summary, we make the following definition.

Definition 29.14. Let E_1 and E_2 be two K -vector spaces, and let $\varphi_1: E_1 \times E_1 \rightarrow K$ and $\varphi_2: E_2 \times E_2 \rightarrow K$ be two sesquilinear forms. Assume that l_{φ_1} and r_{φ_1} are bijective, so that φ_1 is nondegenerate. For every linear map $f: E_1 \rightarrow E_2$, there exist unique linear maps $f^{*l}: E_2 \rightarrow E_1$ and $f^{*r}: E_2 \rightarrow E_1$, such that

$$\begin{aligned} \varphi_2(f(x), u) &= \varphi_1(x, f^{*l}(u)), & \text{for all } x \in E_1, \text{ and all } u \in E_2 \\ \varphi_2(u, f(x)) &= \varphi_1(f^{*r}(u), x), & \text{for all } x \in E_1, \text{ and all } u \in E_2. \end{aligned}$$

The map f^{*l} is called the *left adjoint* of f , and the map f^{*r} is called the *right adjoint* of f .

If E_1 and E_2 are finite-dimensional with bases (e_1, \dots, e_m) and (f_1, \dots, f_n) , then we can work out the matrices A^{*l} and A^{*r} corresponding to the left adjoint f^{*l} and the right adjoint f^{*r} of f . Assume that f is represented by the $n \times m$ matrix A , φ_1 is represented by the $m \times m$ matrix M_1 , and φ_2 is represented by the $n \times n$ matrix M_2 . Since

$$\begin{aligned} \varphi_1(x, f^{*l}(u)) &= (A^{*l}u)^* M_1 x = u^*(A^{*l})^* M_1 x \\ \varphi_2(f(x), u) &= u^* M_2 A x \end{aligned}$$

we find that $(A^{*l})^* M_1 = M_2 A$, that is $(A^{*l})^* = M_2 A M_1^{-1}$, and similarly

$$\begin{aligned} \varphi_1(f^{*r}(u), x) &= x^* M_1 A^{*r} u \\ \varphi_2(u, f(x)) &= (Ax)^* M_2 u = x^* A^* M_2 u, \end{aligned}$$

we have $M_1 A^{*r} = A^* M_2$, that is $A^{*r} = (M_1)^{-1} A^* M_2$. Thus, we obtain

$$\begin{aligned} A^{*l} &= (M_1^*)^{-1} A^* M_2^* \\ A^{*r} &= (M_1)^{-1} A^* M_2. \end{aligned}$$

If φ_1 and φ_2 are symmetric bilinear forms, then $f^{*l} = f^{*r}$. This also holds if φ is ϵ -Hermitian. Indeed, since

$$\varphi_2(u, f(x)) = \varphi_1(f^{*r}(u), x),$$

we get

$$\epsilon\overline{\varphi_2(f(x), u)} = \epsilon\overline{\varphi_1(x, f^{*r}(u))},$$

and since $\lambda \mapsto \bar{\lambda}$ is an involution, we get

$$\varphi_2(f(x), u) = \varphi_1(x, f^{*r}(u)).$$

Since we also have

$$\varphi_2(f(x), u) = \varphi_1(x, f^{*l}(u)),$$

we obtain

$$\varphi_1(x, f^{*r}(u)) = \varphi_1(x, f^{*l}(u)) \quad \text{for all } x \in E_1, \text{ and all } u \in E_2,$$

and since φ_1 is nondegenerate, we conclude that $f^{*l} = f^{*r}$. Whenever $f^{*l} = f^{*r}$, we use the simpler notation f^* .

If $f: E_1 \rightarrow E_2$ and $g: E_1 \rightarrow E_2$ are two linear maps, we have the following properties:

$$\begin{aligned} (f + g)^{*l} &= f^{*l} + g^{*l} \\ \text{id}^{*l} &= \text{id} \\ (\lambda f)^{*l} &= \bar{\lambda} f^{*l}, \end{aligned}$$

and similarly for right adjoints. If E_3 is another space, φ_3 is a sesquilinear form on E_3 , and if l_{φ_2} and r_{φ_2} are bijective, then for any linear maps $f: E_1 \rightarrow E_2$ and $g: E_2 \rightarrow E_3$, we have

$$(g \circ f)^{*l} = f^{*l} \circ g^{*l},$$

and similarly for right adjoints. Furthermore, if $E_1 = E_2 = E$ and $\varphi: E \times E \rightarrow K$ is ϵ -Hermitian, for any linear map $f: E \rightarrow E$ (recall that in this case $f^{*l} = f^{*r} = f^*$), we have

$$f^{**} = \epsilon\bar{\epsilon}f.$$

29.5 Isometries Associated with Sesquilinear Forms

The notion of adjoint is a good tool to investigate the notion of isometry between spaces equipped with sesquilinear forms. First, we define metric maps and isometries.

Definition 29.15. If (E_1, φ_1) and (E_2, φ_2) are two pairs of spaces and sesquilinear maps $\varphi_1: E_1 \times E_1 \rightarrow K$ and $\varphi_2: E_2 \times E_2 \rightarrow K$, a *metric map* from (E_1, φ_1) to (E_2, φ_2) is a linear map $f: E_1 \rightarrow E_2$ such that

$$\varphi_1(u, v) = \varphi_2(f(u), f(v)) \quad \text{for all } u, v \in E_1.$$

We say that φ_1 and φ_2 are *equivalent* iff there is a metric map $f: E_1 \rightarrow E_2$ which is bijective. Such a metric map is called an *isometry*.

The problem of classifying sesquilinear forms up to equivalence is an important but very difficult problem. Solving this problem depends intimately on properties of the field K , and a complete answer is only known in a few cases. The problem is easily solved for $K = \mathbb{R}$, $K = \mathbb{C}$. It is also solved for finite fields and for $K = \mathbb{Q}$ (the rationals), but the solution is surprisingly involved!

It is hard to say anything interesting if φ_1 is degenerate and if the linear map f does not have adjoints. The next few propositions make use of natural conditions on φ_1 that yield a useful criterion for being a metric map.

Proposition 29.16. *With the same assumptions as in Definition 29.14 (which imply that φ_1 is nondegenerate), if $f: E_1 \rightarrow E_2$ is a bijective linear map, then we have*

$$\begin{aligned} \varphi_1(x, y) &= \varphi_2(f(x), f(y)) \quad \text{for all } x, y \in E_1 \text{ iff} \\ f^{-1} &= f^{*l} = f^{*r}. \end{aligned}$$

Proof. We have

$$\varphi_1(x, y) = \varphi_2(f(x), f(y))$$

iff

$$\varphi_1(x, y) = \varphi_2(f(x), f(y)) = \varphi_1(x, f^{*l}(f(y)))$$

iff

$$\varphi_1(x, (\text{id} - f^{*l} \circ f)(y)) = 0 \quad \text{for all } x \in E_1 \text{ and all } y \in E_2.$$

Since φ_1 is nondegenerate, we must have

$$f^{*l} \circ f = \text{id},$$

which implies that $f^{-1} = f^{*l}$. Similarly,

$$\varphi_1(x, y) = \varphi_2(f(x), f(y))$$

iff

$$\varphi_1(x, y) = \varphi_2(f(x), f(y)) = \varphi_1(f^{*r}(f(x)), y)$$

iff

$$\varphi_1((\text{id} - f^{*r} \circ f)(x), y) = 0 \quad \text{for all } x \in E_1 \text{ and all } y \in E_2.$$

Since φ_1 is nondegenerate, we must have

$$f^{*r} \circ f = \text{id},$$

which implies that $f^{-1} = f^{*r}$. Therefore, $f^{-1} = f^{*l} = f^{*r}$. For the converse, do the computations in reverse. \square

As a corollary, we get the following important proposition.

Proposition 29.17. *If $\varphi: E \times E \rightarrow K$ is a sesquilinear map, and if l_φ and r_φ are bijective, for every bijective linear map $f: E \rightarrow E$, then we have*

$$\begin{aligned}\varphi(f(x), f(y)) &= \varphi(x, y) \quad \text{for all } x, y \in E \text{ iff} \\ f^{-1} &= f^{*l} = f^{*r}.\end{aligned}$$

We also have the following facts.

Proposition 29.18. (1) *If $\varphi: E \times E \rightarrow K$ is a sesquilinear map and if l_φ is injective, then for every linear map $f: E \rightarrow E$, if*

$$\varphi(f(x), f(y)) = \varphi(x, y) \quad \text{for all } x, y \in E, \tag{*}$$

then f is injective.

(2) *If E is finite-dimensional and if φ is nondegenerate, then the linear maps $f: E \rightarrow E$ satisfying $(*)$ form a group. The inverse of f is given by $f^{-1} = f^*$.*

Proof. (1) If $f(x) = 0$, then

$$\varphi(x, y) = \varphi(f(x), f(y)) = \varphi(0, f(y)) = 0 \quad \text{for all } y \in E.$$

Since l_φ is injective, we must have $x = 0$, and thus f is injective.

(2) If E is finite-dimensional, since a linear map satisfying $(*)$ is injective, it is a bijection. By Proposition 29.17, we have $f^{-1} = f^*$. We also have

$$\varphi(f(x), f(y)) = \varphi((f^* \circ f)(x), y) = \varphi(x, y) = \varphi((f \circ f^*)(x), y) = \varphi(f^*(x), f^*(y)),$$

which shows that f^* satisfies $(*)$. If $\varphi(f(x), f(y)) = \varphi(x, y)$ for all $x, y \in E$ and $\varphi(g(x), g(y)) = \varphi(x, y)$ for all $x, y \in E$, then we have

$$\varphi((g \circ f)(x), (g \circ f)(y)) = \varphi(f(x), f(y)) = \varphi(x, y) \quad \text{for all } x, y \in E.$$

Obviously, the identity map id_E satisfies $(*)$. Therefore, the set of linear maps satisfying $(*)$ is a group. \square

The above considerations motivate the following definition.

Definition 29.16. Let $\varphi: E \times E \rightarrow K$ be a sesquilinear map, and assume that E is finite-dimensional and that φ is nondegenerate. A linear map $f: E \rightarrow E$ is an *isometry* of E (with respect to φ) iff

$$\varphi(f(x), f(y)) = \varphi(x, y) \quad \text{for all } x, y \in E.$$

The set of all isometries of E is a group denoted by $\mathbf{Isom}(\varphi)$.

If φ is symmetric, then the group $\mathbf{Isom}(\varphi)$ is denoted $\mathbf{O}(\varphi)$ and called the *orthogonal group* of φ . If φ is alternating, then the group $\mathbf{Isom}(\varphi)$ is denoted $\mathbf{Sp}(\varphi)$ and called the *symplectic group* of φ . If φ is ϵ -Hermitian, then the group $\mathbf{Isom}(\varphi)$ is denoted $\mathbf{U}_\epsilon(\varphi)$ and called the ϵ -*unitary group* of φ . When $\epsilon = 1$, we drop ϵ and just say *unitary group*.

If (e_1, \dots, e_n) is a basis of E , φ is represented by the $n \times n$ matrix M , and f is represented by the $n \times n$ matrix A , since $A^{-1} = A^{*l} = A^{*r} = M^{-1}A^*M$, then we find that $f \in \mathbf{Isom}(\varphi)$ iff

$$A^*MA = M,$$

and A^{-1} is given by $A^{-1} = M^{-1}A^*M$.

More specifically, we define the following groups, using the matrices $I_{p,q}, J_{m,m}$ and $A_{m,m}$ defined at the end of Section 29.1.

(1) $K = \mathbb{R}$. We have

$$\begin{aligned}\mathbf{O}(n) &= \{A \in M_n(\mathbb{R}) \mid A^\top A = I_n\} \\ \mathbf{O}(p, q) &= \{A \in M_{p+q}(\mathbb{R}) \mid A^\top I_{p,q} A = I_{p,q}\} \\ \mathbf{Sp}(2n, \mathbb{R}) &= \{A \in M_{2n}(\mathbb{R}) \mid A^\top J_{n,n} A = J_{n,n}\} \\ \mathbf{SO}(n) &= \{A \in M_n(\mathbb{R}) \mid A^\top A = I_n, \det(A) = 1\} \\ \mathbf{SO}(p, q) &= \{A \in M_{p+q}(\mathbb{R}) \mid A^\top I_{p,q} A = I_{p,q}, \det(A) = 1\}.\end{aligned}$$

The group $\mathbf{O}(n)$ is the *orthogonal group*, $\mathbf{Sp}(2n, \mathbb{R})$ is the *real symplectic group*, and $\mathbf{SO}(n)$ is the *special orthogonal group*. We can define the group

$$\{A \in M_{2n}(\mathbb{R}) \mid A^\top A = I_{2n}\},$$

but it is isomorphic to $\mathbf{O}(n, n)$.

(2) $K = \mathbb{C}$. We have

$$\begin{aligned}\mathbf{U}(n) &= \{A \in M_n(\mathbb{C}) \mid A^* A = I_n\} \\ \mathbf{U}(p, q) &= \{A \in M_{p+q}(\mathbb{C}) \mid A^* I_{p,q} A = I_{p,q}\} \\ \mathbf{Sp}(2n, \mathbb{C}) &= \{A \in M_{2n}(\mathbb{C}) \mid A^\top J_{n,n} A = J_{n,n}\} \\ \mathbf{SU}(n) &= \{A \in M_n(\mathbb{C}) \mid A^* A = I_n, \det(A) = 1\} \\ \mathbf{SU}(p, q) &= \{A \in M_{p+q}(\mathbb{C}) \mid A^* I_{p,q} A = I_{p,q}, \det(A) = 1\}.\end{aligned}$$

The group $\mathbf{U}(n)$ is the *unitary group*, $\mathbf{Sp}(2n, \mathbb{C})$ is the *complex symplectic group*, and $\mathbf{SU}(n)$ is the *special unitary group*.

It can be shown that if $A \in \mathbf{Sp}(2n, \mathbb{R})$ or if $A \in \mathbf{Sp}(2n, \mathbb{C})$, then $\det(A) = 1$.

29.6 Totally Isotropic Subspaces

In this section, we deal with ϵ -Hermitian forms, $\varphi: E \times E \rightarrow K$. In general, E may have subspaces U such that $U \cap U^\perp \neq (0)$, or worse, such that $U \subseteq U^\perp$ (that is, φ is zero on U). We will see that such subspaces play a crucial role in the decomposition of E into orthogonal subspaces.

Definition 29.17. Given an ϵ -Hermitian form $\varphi: E \times E \rightarrow K$, a nonzero vector $u \in E$ is said to be *isotropic* if $\varphi(u, u) = 0$. It is convenient to consider 0 to be isotropic. Given any subspace U of E , the subspace $\text{rad}(U) = U \cap U^\perp$ is called the *radical* of U . We say that

- (i) U is *degenerate* if $\text{rad}(U) \neq (0)$ (equivalently if there is some nonzero vector $u \in U$ such that $u \in U^\perp$). Otherwise, we say that U is *nondegenerate*.
- (ii) U is *totally isotropic* if $U \subseteq U^\perp$ (equivalently if the restriction of φ to U is zero).

By definition, the trivial subspace $U = (0) (= \{0\})$ is nondegenerate. Observe that a subspace U is nondegenerate iff the restriction of φ to U is nondegenerate. A degenerate subspace is sometimes called an *isotropic* subspace. Other authors say that a subspace U is *isotropic* if it contains some (nonzero) isotropic vector. A subspace which has no nonzero isotropic vector is often called *anisotropic*. The space of all isotropic vectors is a cone often called the *light cone* (a terminology coming from the theory of relativity). This is not to be confused with the cone of silence (from Get Smart)! It should also be noted that some authors (such as Serre) use the term *isotropic* instead of *totally isotropic*. The apparent lack of standard terminology is almost as bad as in graph theory!

It is clear that any direct sum of pairwise orthogonal totally isotropic subspaces is totally isotropic. Thus, every totally isotropic subspace is contained in some maximal totally isotropic subspace. Here is another fact that we will use all the time: if V is a totally isotropic subspace and if U is a subspace of V , then U is totally isotropic.

This is because by definition V is isotropic if $V \subseteq V^\perp$, and since $U \subseteq V$ we get $V^\perp \subseteq U^\perp$, so $U \subseteq V \subseteq V^\perp \subseteq U^\perp$, which shows that U is totally isotropic.

First, let us show that in order to study an ϵ -Hermitian form on a space E , it suffices to restrict our attention to nondegenerate forms.

Proposition 29.19. *Given an ϵ -Hermitian form $\varphi: E \times E \rightarrow K$ on E , we have:*

- (a) *If U and V are any two orthogonal subspaces of E , then*

$$\text{rad}(U + V) = \text{rad}(U) + \text{rad}(V).$$

- (b) $\text{rad}(\text{rad}(E)) = \text{rad}(E)$.

(c) If U is any subspace supplementary to $\text{rad}(E)$, so that

$$E = \text{rad}(E) \oplus U,$$

then U is nondegenerate, and $\text{rad}(E)$ and U are orthogonal.

Proof. (a) If U and V are orthogonal, then $U \subseteq V^\perp$ and $V \subseteq U^\perp$. We get

$$\begin{aligned} \text{rad}(U + V) &= (U + V) \cap (U + V)^\perp \\ &= (U + V) \cap U^\perp \cap V^\perp \\ &= U \cap U^\perp \cap V^\perp + V \cap U^\perp \cap V^\perp \\ &= U \cap U^\perp + V \cap V^\perp \\ &= \text{rad}(U) + \text{rad}(V). \end{aligned}$$

(b) By definition, $\text{rad}(E) = E^\perp$, and obviously $E = E^{\perp\perp}$, so we get

$$\text{rad}(\text{rad}(E)) = E^\perp \cap E^{\perp\perp} = E^\perp \cap E = E^\perp = \text{rad}(E).$$

(c) If $E = \text{rad}(E) \oplus U$, by definition of $\text{rad}(E)$, the subspaces $\text{rad}(E)$ and U are orthogonal. From (a) and (b), we get

$$\text{rad}(E) = \text{rad}(E) + \text{rad}(U).$$

Since $\text{rad}(U) = U \cap U^\perp \subseteq U$ and since $\text{rad}(E) \oplus U$ is a direct sum, we have a direct sum

$$\text{rad}(E) = \text{rad}(E) \oplus \text{rad}(U),$$

which implies that $\text{rad}(U) = (0)$; that is, U is nondegenerate. \square

Proposition 29.19(c) shows that the restriction of φ to any supplement U of $\text{rad}(E)$ is nondegenerate and φ is zero on $\text{rad}(U)$, so we may restrict our attention to nondegenerate forms.

The following is also a key result.

Proposition 29.20. *Given an ϵ -Hermitian form $\varphi: E \times E \rightarrow K$ on E , if U is a finite-dimensional nondegenerate subspace of E , then $E = U \oplus U^\perp$.*

Proof. By hypothesis, the restriction φ_U of φ to U is nondegenerate, so the semilinear map $r_{\varphi_U}: U \rightarrow U^*$ is injective. Since U is finite-dimensional, r_{φ_U} is actually bijective, so for every $v \in E$, if we consider the linear form in U^* given by $u \mapsto \varphi(u, v)$ ($u \in U$), there is a unique $v_0 \in U$ such that

$$\varphi(u, v_0) = \varphi(u, v) \quad \text{for all } u \in U;$$

that is, $\varphi(u, v - v_0) = 0$ for all $u \in U$, so $v - v_0 \in U^\perp$. It follows that $v = v_0 + v - v_0$, with $v_0 \in U$ and $v - v_0 \in U^\perp$, and since U is nondegenerate $U \cap U^\perp = (0)$, and $E = U \oplus U^\perp$. \square

As a corollary of Proposition 29.20, we get the following result.

Proposition 29.21. *Given an ϵ -Hermitian form $\varphi: E \times E \rightarrow K$ on E , if φ is nondegenerate and if U is a finite-dimensional subspace of E , then $\text{rad}(U) = \text{rad}(U^\perp)$, and the following conditions are equivalent:*

- (i) U is nondegenerate.
- (ii) U^\perp is nondegenerate.
- (iii) $E = U \oplus U^\perp$.

Proof. By definition, $\text{rad}(U^\perp) = U^\perp \cap U^{\perp\perp}$, and since φ is nondegenerate and U is finite-dimensional, $U^{\perp\perp} = U$, so $\text{rad}(U^\perp) = U^\perp \cap U^{\perp\perp} = U \cap U^\perp = \text{rad}(U)$.

By Proposition 29.20, (i) implies (iii). If $E = U \oplus U^\perp$, then $\text{rad}(U) = U \cap U^\perp = (0)$, so U is nondegenerate and (iii) implies (i). Since $\text{rad}(U^\perp) = \text{rad}(U)$, (iii) also implies (ii). Now, if U^\perp is nondegenerate, we have $U^\perp \cap U^{\perp\perp} = (0)$, and since $U \subseteq U^{\perp\perp}$, we get

$$U \cap U^\perp \subseteq U^{\perp\perp} \cap U^\perp = (0),$$

which shows that U is nondegenerate, proving the implication (ii) \implies (i). \square

If E is finite-dimensional, we have the following results.

Proposition 29.22. *Given an ϵ -Hermitian form $\varphi: E \times E \rightarrow K$ on a finite-dimensional space E , if φ is nondegenerate, then for every subspace U of E we have*

- (i) $\dim(U) + \dim(U^\perp) = \dim(E)$.
- (ii) $U^{\perp\perp} = U$.

Proof. (i) Since φ is nondegenerate and E is finite-dimensional, the semilinear map $l_\varphi: E \rightarrow E^*$ is bijective. By transposition, the inclusion $i: U \rightarrow E$ yields a surjection $r: E^* \rightarrow U^*$ (with $r(f) = f \circ i$ for every $f \in E^*$; the map $f \circ i$ is the restriction of the linear form f to U). It follows that the semilinear map $r \circ l_\varphi: E \rightarrow U^*$ given by

$$(r \circ l_\varphi)(x)(u) = \overline{\varphi(x, u)} \quad x \in E, u \in U$$

is surjective, and its kernel is U^\perp . Thus, we have

$$\dim(U^*) + \dim(U^\perp) = \dim(E),$$

and since $\dim(U) = \dim(U^*)$ because U is finite-dimensional, we get

$$\dim(U) + \dim(U^\perp) = \dim(U^*) + \dim(U^\perp) = \dim(E).$$

(ii) Applying the above formula to U^\perp , we deduce that $\dim(U) = \dim(U^{\perp\perp})$. Since $U \subseteq U^{\perp\perp}$, we must have $U^{\perp\perp} = U$. \square

Remark: We already proved in Proposition 29.13 that if U is finite-dimensional, then $\text{codim}(U^\perp) = \dim(U)$ and $U^{\perp\perp} = U$, but it doesn't hurt to give another proof. Observe that (i) implies that

$$\dim(U) + \dim(\text{rad}(U)) \leq \dim(E).$$

We can now proceed with the Witt decomposition, but before that, we quickly take care of the structure theorem for alternating bilinear forms (the case where $\varphi(u, u) = 0$ for all $u \in E$). For an alternating bilinear form, the space E is totally isotropic. For example in dimension 2, the matrix

$$B = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$$

defines the alternating form given by

$$\varphi((x_1, y_1), (x_2, y_2)) = x_1y_2 - x_2y_1.$$

This case is surprisingly general.

Proposition 29.23. *Let $\varphi: E \times E \rightarrow K$ be an alternating bilinear form on E . If $u, v \in E$ are two (nonzero) vectors such that $\varphi(u, v) = \lambda \neq 0$, then u and v are linearly independent. If we let $u_1 = \lambda^{-1}u$ and $v_1 = v$, then $\varphi(u_1, v_1) = 1$, and the restriction of φ to the plane spanned by u_1 and v_1 is represented by the matrix*

$$\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

Proof. If u and v were linearly dependent, as $u, v \neq 0$, we could write $v = \mu u$ for some $\mu \neq 0$, but then, since φ is alternating, we would have

$$\lambda = \varphi(u, v) = \varphi(u, \mu u) = \mu\varphi(u, u) = 0,$$

contradicting the fact that $\lambda \neq 0$. The rest is obvious. \square

Proposition 29.23 yields a plane spanned by two vectors u_1, v_1 such that $\varphi(u_1, u_1) = \varphi(v_1, v_1) = 0$ and $\varphi(u_1, v_1) = 1$. Such a plane is called a *hyperbolic plane*. If E is finite-dimensional, we obtain the following theorem.

Theorem 29.24. *Let $\varphi: E \times E \rightarrow K$ be an alternating bilinear form on a space E of finite dimension n . Then, there is a direct sum decomposition of E into pairwise orthogonal subspaces*

$$E = W_1 \oplus \cdots \oplus W_r \oplus \text{rad}(E),$$

where each W_i is a hyperbolic plane and $\text{rad}(E) = E^\perp$. Therefore, there is a basis of E of the form

$$(u_1, v_1, \dots, u_r, v_r, w_1, \dots, w_{n-2r}),$$

with respect to which the matrix representing φ is a block diagonal matrix M of the form

$$M = \begin{pmatrix} J & & & 0 \\ & J & & \\ & & \ddots & \\ 0 & & & J \\ & & & 0_{n-2r} \end{pmatrix},$$

with

$$J = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

Proof. If $\varphi = 0$, then $E = E^\perp$ and we are done. Otherwise, there are two nonzero vectors $u, v \in E$ such that $\varphi(u, v) \neq 0$, so by Proposition 29.23, we obtain a hyperbolic plane W_2 spanned by two vectors u_1, v_1 such that $\varphi(u_1, v_1) = 1$. The subspace W_1 is nondegenerate (for example, $\det(J) = -1$), so by Proposition 29.21, we get a direct sum

$$E = W_1 \oplus W_1^\perp.$$

By Proposition 29.14, we also have

$$E^\perp = (W_1 \oplus W_1^\perp)^\perp = W_1^\perp \cap W_1^{\perp\perp} = \text{rad}(W_1^\perp).$$

By the induction hypothesis applied to W_1^\perp , we obtain our theorem. \square

The following corollary follows immediately.

Proposition 29.25. *Let $\varphi: E \times E \rightarrow K$ be an alternating bilinear form on a space E of finite dimension n .*

- (1) *The rank of φ is even.*
- (2) *If φ is nondegenerate, then $\dim(E) = n$ is even.*
- (3) *Two alternating bilinear forms $\varphi_1: E_1 \times E_1 \rightarrow K$ and $\varphi_2: E_2 \times E_2 \rightarrow K$ are equivalent iff $\dim(E_1) = \dim(E_2)$ and φ_1 and φ_2 have the same rank.*

The only part that requires a proof is part (3), which is left as an easy exercise.

If φ is nondegenerate, then $n = 2r$, and a basis of E as in Theorem 29.24 is called a *symplectic basis*. The space E is called a *hyperbolic space* (or *symplectic space*).

Observe that if we reorder the vectors in the basis

$$(u_1, v_1, \dots, u_r, v_r, w_1, \dots, w_{n-2r})$$

to obtain the basis

$$(u_1, \dots, u_r, v_1, \dots, v_r, w_1, \dots, w_{n-2r}),$$

then the matrix representing φ becomes

$$\begin{pmatrix} 0 & I_r & 0 \\ -I_r & 0 & 0 \\ 0 & 0 & 0_{n-2r} \end{pmatrix}.$$

This particularly simple matrix is often preferable, especially when dealing with the matrices (symplectic matrices) representing the isometries of φ (in which case $n = 2r$).

As a warm up for Proposition 29.29 of the next section, we prove an analog of Proposition 29.23 in the case of a symmetric bilinear form.

Proposition 29.26. *Let $\varphi: E \times E \rightarrow K$ be a nondegenerate symmetric bilinear form with K a field of characteristic different from 2. For any nonzero isotropic vector u , there is another nonzero isotropic vector v such that $\varphi(u, v) = 2$, and u and v are linearly independent. In the basis $(u, v/2)$, the restriction of φ to the plane spanned by u and $v/2$ is of the form*

$$\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}.$$

Proof. Since φ is nondegenerate, there is some nonzero vector z such that (rescaling z if necessary) $\varphi(u, z) = 1$. If

$$v = 2z - \varphi(z, z)u,$$

then since $\varphi(u, u) = 0$ and $\varphi(u, z) = 1$, note that

$$\varphi(u, v) = \varphi(u, 2z - \varphi(z, z)u) = 2\varphi(u, z) - \varphi(z, z)\varphi(u, u) = 2,$$

and

$$\begin{aligned} \varphi(v, v) &= \varphi(2z - \varphi(z, z)u, 2z - \varphi(z, z)u) \\ &= 4\varphi(z, z) - 4\varphi(z, z)\varphi(u, z) + \varphi(z, z)^2\varphi(u, u) \\ &= 4\varphi(z, z) - 4\varphi(z, z) = 0. \end{aligned}$$

If u and z were linearly dependent, as $u, z \neq 0$, we could write $z = \mu u$ for some $\mu \neq 0$, but then, we would have

$$\varphi(u, z) = \varphi(u, \mu u) = \mu\varphi(u, u) = 0,$$

contradicting the fact that $\varphi(u, z) \neq 0$. Then u and $v = 2z - \varphi(z, z)u$ are also linearly independent, since otherwise z could be expressed as a multiple of u . The rest is obvious. \square

Proposition 29.26 yields a plane spanned by two vectors u_1, v_1 such that $\varphi(u_1, u_1) = \varphi(v_1, v_1) = 0$ and $\varphi(u_1, v_1) = 1$. Such a plane is called an *Artinian plane*. Proposition 29.26 also shows that nonzero isotropic vectors come in pair.

Proposition 29.26 has the following corollary which has applications in number theory; see Serre [157], Chapter IV.

Proposition 29.27. *If Φ is any nondegenerate quadratic form (over a field of characteristic $\neq 2$) such that there is some nonzero vector $x \in E$ with $\Phi(x) = 0$, then for every $\alpha \in K$, there is some $y \in E$ such that $\Phi(y) = \alpha$.*

Proof. Since by hypothesis there is some nonzero vector $u \in E$ with $\Phi(u) = 0$, by Proposition 29.26 there is another isotropic vector v such that u and v are linearly independent and such that (after rescaling) $\varphi(u, v) = 1$. Then for any $\alpha \in K$, check that

$$\Phi\left(u + \frac{\alpha}{2}v\right) = \alpha,$$

as desired. \square

Remark: Some authors refer to the above plane as a *hyperbolic plane*. Berger (and others) point out that this terminology is undesirable because the notion of hyperbolic plane already exists in differential geometry and refers to a very different object.

We leave it as an exercise to figure out that the group of isometries of the Artinian plane, the set of all 2×2 matrices A such that

$$A^\top \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} A = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix},$$

consists of all matrices of the form

$$\begin{pmatrix} \lambda & 0 \\ 0 & \lambda^{-1} \end{pmatrix} \quad \text{or} \quad \begin{pmatrix} 0 & \lambda \\ \lambda^{-1} & 0 \end{pmatrix}, \quad \lambda \in K - \{0\}.$$

In particular, if $K = \mathbb{R}$, then this group denoted $\mathbf{O}(1, 1)$ has four connected components.

We now turn to the Witt decomposition.

29.7 Witt Decomposition

From now on, $\varphi: E \times E \rightarrow K$ is an ϵ -Hermitian form. The following assumption will be needed:

Property (T). For every $u \in E$, there is some $\alpha \in K$ such that $\varphi(u, u) = \alpha + \epsilon\bar{\alpha}$.

Property (T) is always satisfied if φ is alternating, or if K is of characteristic $\neq 2$ and $\epsilon = \pm 1$, with $\alpha = \frac{1}{2}\varphi(u, u)$.

The following (bizarre) technical lemma will be needed.

Lemma 29.28. *Let φ be an ϵ -Hermitian form on E and assume that φ satisfies property (T). For any totally isotropic subspace $U \neq (0)$ of E , for every $x \in E$ not orthogonal to U , and for every $\alpha \in K$, there is some $y \in U$ so that*

$$\varphi(x + y, x + y) = \alpha + \epsilon\bar{\alpha}.$$

Proof. By property (T), we have $\varphi(x, x) = \beta + \epsilon\bar{\beta}$ for some $\beta \in K$. For any $y \in U$, since φ is ϵ -Hermitian, $\varphi(y, x) = \epsilon\overline{\varphi(x, y)}$, and since U is totally isotropic $\varphi(y, y) = 0$, so we have

$$\begin{aligned}\varphi(x+y, x+y) &= \varphi(x, x) + \varphi(x, y) + \varphi(y, x) + \varphi(y, y) \\ &= \beta + \epsilon\bar{\beta} + \varphi(x, y) + \epsilon\overline{\varphi(x, y)} \\ &= \beta + \varphi(x, y) + \epsilon(\beta + \varphi(x, y)).\end{aligned}$$

Since x is not orthogonal to U , the function $y \mapsto \varphi(x, y) + \beta$ is not the constant function. Consequently, this function takes the value α for some $y \in U$, which proves the lemma. \square

Definition 29.18. Let φ be an ϵ -Hermitian form on E . A *weak Witt decomposition* of E is a triple (U, U', W) , such that

- (i) $E = U \oplus U' \oplus W$ (a direct sum).
- (ii) U and U' are totally isotropic.
- (iii) W is nondegenerate and orthogonal to $U \oplus U'$.

We say that a weak Witt decomposition (U, U', W) is *nontrivial* if $U \neq (0)$ and $U' \neq (0)$. Furthermore, if E is finite-dimensional, then $\dim(U) = \dim(U')$ and in a suitable basis, the matrix representing φ is of the form

$$\begin{pmatrix} 0 & A & 0 \\ \epsilon\bar{A} & 0 & 0 \\ 0 & 0 & B \end{pmatrix}$$

We say that φ is a *neutral form* if it is nondegenerate, E is finite-dimensional, and if $W = (0)$. In this case, the matrix B is missing.

A Witt decomposition for which W has no nonzero isotropic vectors (W is anisotropic) is called a *Witt decomposition*.

Observe that if Φ is nondegenerate, then we have the trivial weak Witt decomposition obtained by letting $U = U' = (0)$ and $W = E$. Thus a weak Witt decomposition is informative only if E is not anisotropic (there is some nonzero isotropic vector, *i.e.* some $u \neq 0$ such that $\Phi(u) = 0$), in which case the most informative nontrivial weak Witt decompositions are those for which W is anisotropic and U and U' are as big as possible.

Sometimes, we use the notation $U_1 \overset{\perp}{\oplus} U_2$ to indicate that in a direct sum $U_1 \oplus U_2$, the subspaces U_1 and U_2 are orthogonal. Then, in Definition 29.18, we can write that $E = (U \oplus U') \overset{\perp}{\oplus} W$.

The first step in showing the existence of a Witt decomposition is this.

Proposition 29.29. *Let φ be an ϵ -Hermitian form on E , assume that φ is nondegenerate and satisfies property (T), and let U be any totally isotropic subspace of E of finite dimension $\dim(U) = r \geq 1$.*

- (1) *If U' is any totally isotropic subspace of dimension r and if $U' \cap U^\perp = (0)$, then $U \oplus U'$ is nondegenerate, and for any basis (u_1, \dots, u_r) of U , there is a basis (u'_1, \dots, u'_r) of U' such that $\varphi(u_i, u'_j) = \delta_{ij}$, for all $i, j = 1, \dots, r$.*
- (2) *If W is any totally isotropic subspace of dimension at most r and if $W \cap U^\perp = (0)$, then there exists a totally isotropic subspace U' with $\dim(U') = r$ such that $W \subseteq U'$ and $U' \cap U^\perp = (0)$.*

Proof. (1) Let φ' be the restriction of φ to $U \times U'$. Since $U' \cap U^\perp = (0)$, for any $v \in U'$, if $\varphi(u, v) = 0$ for all $u \in U$, then $v = 0$. Thus, φ' is nondegenerate (we only have to check on the left since φ is ϵ -Hermitian). Then, the assertion about bases follows from the version of Proposition 29.3 for sesquilinear forms. Since U is totally isotropic, $U \subseteq U^\perp$, and since $U' \cap U^\perp = (0)$, we must have $U' \cap U = (0)$, which shows that we have a direct sum $U \oplus U'$.

It remains to prove that $U + U'$ is nondegenerate. Observe that

$$H = (U + U') \cap (U + U')^\perp = (U + U') \cap U^\perp \cap U'^\perp.$$

Since U is totally isotropic, $U \subseteq U^\perp$, and since $U' \cap U^\perp = (0)$, we have

$$(U + U') \cap U^\perp = (U \cap U^\perp) + (U' \cap U^\perp) = U + (0) = U,$$

thus $H = U \cap U'^\perp$. Since φ' is nondegenerate, $U \cap U'^\perp = (0)$, so $H = (0)$ and $U + U'$ is nondegenerate.

(2) We proceed by descending induction on $s = \dim(W)$. The base case $s = r$ is trivial. For the induction step, it suffices to prove that if $s < r$, then there is a totally isotropic subspace W' containing W such that $\dim(W') = s + 1$ and $W' \cap U^\perp = (0)$.

Since $s = \dim(W) < \dim(U)$, the restriction of φ to $U \times W$ is degenerate. Since $W \cap U^\perp = (0)$, we must have $U \cap W^\perp \neq (0)$. We claim that

$$W^\perp \not\subseteq W + U^\perp.$$

If we had

$$W^\perp \subseteq W + U^\perp,$$

then because U and W are finite-dimensional and φ is nondegenerate, by Proposition 29.13, $U^{\perp\perp} = U$ and $W^{\perp\perp} = W$, so by taking orthogonals, $W^\perp \subseteq W + U^\perp$ would yield

$$(W + U^\perp)^\perp \subseteq W^{\perp\perp},$$

that is,

$$W^\perp \cap U \subseteq W,$$

thus $W^\perp \cap U \subseteq W \cap U$, and since U is totally isotropic, $U \subseteq U^\perp$, which yields

$$W^\perp \cap U \subseteq W \cap U \subseteq W \cap U^\perp = (0),$$

contradicting the fact that $U \cap W^\perp \neq (0)$.

Therefore, there is some $u \in W^\perp$ such that $u \notin W + U^\perp$. Since $U \subseteq U^\perp$, we can add to u any vector $z \in W^\perp \cap U \subseteq U^\perp$ so that $u + z \in W^\perp$ and $u + z \notin W + U^\perp$ (if $u + z \in W + U^\perp$, since $z \in U^\perp$, then $u \in W + U^\perp$, a contradiction). Since $W^\perp \cap U \neq (0)$ is totally isotropic and $u \notin W + U^\perp = (W^\perp \cap U)^\perp$, we can invoke Lemma 29.28 to find a $z \in W^\perp \cap U$ such that $\varphi(u + z, u + z) = 0$. See Figure 29.1. If we write $x = u + z$, then $x \notin W + U^\perp$, so $W' = W + Kx$ is a totally isotropic subspace of dimension $s + 1$. Furthermore, we claim that $W' \cap U^\perp = 0$.

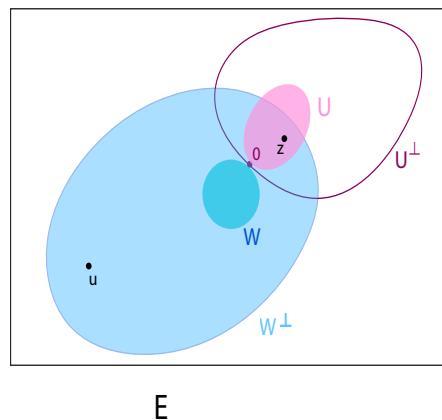

Figure 29.1: A schematic illustration of W and $x = u + z$

Otherwise, we would have $y = w + \lambda x \in U^\perp$, for some $w \in W$ and some $\lambda \in K$, and then we would have $\lambda x = -w + y \in W + U^\perp$. If $\lambda \neq 0$, then $x \in W + U^\perp$, a contradiction. Therefore, $\lambda = 0$, $y = w$, and since $y \in U^\perp$ and $w \in W$, we have $y \in W \cap U^\perp = (0)$, which means that $y = 0$. Therefore, W' is the required subspace and this completes the proof. \square

Here are some consequences of Proposition 29.29. If we set $W = (0)$ in Proposition 29.29(2), then we get the following theorem showing that if E is not anisotropic (there is some nonzero isotropic vector) then weak nontrivial Witt decompositions exist.

Theorem 29.30. *Let φ be an ϵ -Hermitian form on E which is nondegenerate and satisfies property (T). For any totally isotropic subspace U of E of finite dimension $r \geq 1$, there exists a totally isotropic subspace U' of dimension r such that $U \cap U' = (0)$ and $U \oplus U'$ is nondegenerate. As a consequence, if E is not anisotropic, then $(U, U', (U \oplus U')^\perp)$ is a weak nontrivial Witt decomposition for E . Furthermore, by Proposition 29.29(1), the block A in the matrix of φ is the identity matrix.*

Proposition 29.31. *Any two ϵ -Hermitian neutral forms satisfying property (T) defined on spaces of the same dimension are equivalent.*

The following proposition shows that every subspace U of E can be embedded into a nondegenerate subspace. It is needed to prove a version of the Witt extension theorem (Theorem 29.48).

Proposition 29.32. *Let φ be an ϵ -Hermitian form on E which is nondegenerate and satisfies property (T). For any subspace U of E of finite dimension, if we write*

$$U = V \overset{\perp}{\oplus} W,$$

for some orthogonal complement W of $V = \text{rad}(U)$, and if we let $r = \dim(\text{rad}(U))$, then there exists a totally isotropic subspace V' of dimension r such that $V \cap V' = (0)$, and $(V \oplus V') \overset{\perp}{\oplus} W = V' \oplus U$ is nondegenerate. Furthermore, any isometry f from U into another space (E', φ') where φ' is an ϵ -Hermitian form satisfying the same assumptions as φ can be extended to an isometry on $(V \oplus V') \overset{\perp}{\oplus} W$.

Proof. Since W is nondegenerate, W^\perp is also nondegenerate, and $V \subseteq W^\perp$. Therefore, we can apply Theorem 29.30 to the restriction of φ to W^\perp and to V to obtain the required V' . We know that $V \oplus V'$ is nondegenerate and orthogonal to W , which is also nondegenerate, so $(V \oplus V') \overset{\perp}{\oplus} W = V' \oplus U$ is nondegenerate.

We leave the second statement about extending f as an exercise (use the fact that $f(U) = f(V) \overset{\perp}{\oplus} f(W)$, where $V_1 = f(V)$ is totally isotropic of dimension r , to find another totally isotropic subspace V'_1 of dimension r such that $V_1 \cap V'_1 = (0)$ and $V_1 \oplus V'_1$ is orthogonal to $f(W)$). \square

The subspace $(V \oplus V') \overset{\perp}{\oplus} W = V' \oplus U$ is often called a *nondegenerate completion* of U . The subspace $V \oplus V'$ is called an *Artinian space*. Proposition 29.29 shows that $V \oplus V'$ has a basis $(u_1, v_1, \dots, u_r, v_r)$ consisting of vectors $u_i \in V$ and $v_j \in V'$ such that $\varphi(u_i, u_j) = \delta_{ij}$. The subspace spanned by (u_i, v_i) is an Artinian plane, so $V \oplus V'$ is the orthogonal direct sum of r Artinian planes. Such a space is often denoted by Ar_{2r} .

In order to obtain the stronger version of the Witt decomposition when φ has some nonzero isotropic vector and W is anisotropic we now sharpen Proposition 29.29

Theorem 29.33. *Let φ be an ϵ -Hermitian form on E which is nondegenerate and satisfies property (T). Let U_1 and U_2 be two totally isotropic maximal subspaces of E , with U_1 or U_2 of finite dimension ≥ 1 . Write $U = U_1 \cap U_2$, let S_1 be a supplement of U in U_1 and S_2 be a supplement of U in U_2 (so that $U_1 = U \oplus S_1$, $U_2 = U \oplus S_2$), and let $S = S_1 + S_2$. Then, there exist two subspaces W and D of E such that:*

- (a) *The subspaces S , $U + W$, and D are nondegenerate and pairwise orthogonal.*

(b) We have a direct sum $E = S \overset{\perp}{\oplus} (U \oplus W) \overset{\perp}{\oplus} D$.

(c) The subspace D contains no nonzero isotropic vector (D is anisotropic).

(d) The subspace W is totally isotropic.

Furthermore, U_1 and U_2 are both finite dimensional, and we have $\dim(U_1) = \dim(U_2)$, $\dim(W) = \dim(U)$, $\dim(S_1) = \dim(S_2)$, and $\text{codim}(D) = 2\dim(F_1)$.

Proof. First observe that if X is a totally isotropic maximal subspace of E , then any isotropic vector $x \in E$ orthogonal to X must belong to X , since otherwise, $X + Kx$ would be a totally isotropic subspace strictly containing X , contradicting the maximality of X . As a consequence, if x_i is any isotropic vector such that $x_i \in U_i^\perp$ (for $i = 1, 2$), then $x_i \in U_i$.

We claim that

$$S_1 \cap S_2^\perp = (0) \quad \text{and} \quad S_2 \cap S_1^\perp = (0).$$

Assume that $y \in S_1$ is orthogonal to S_2 . Since $U_1 = U \oplus S_1$ and U_1 is totally isotropic, y is orthogonal to U_1 , and thus orthogonal to U , so that y is orthogonal to $U_2 = U \oplus S_2$. Since $S_1 \subseteq U_1$ and U_1 is totally isotropic, y is an isotropic vector orthogonal to U_2 , which by a previous remark implies that $y \in U_2$. Then, since $S_1 \subseteq U_1$ and $U \oplus S_1$ is a direct sum, we have

$$y \in S_1 \cap U_2 = S_1 \cap U_1 \cap U_2 = S_1 \cap U = (0).$$

Therefore $S_1 \cap S_2^\perp = (0)$. A similar proof shows that $S_2 \cap S_1^\perp = (0)$. If U_1 is finite-dimensional (the case where U_2 is finite-dimensional is similar), then S_1 is finite-dimensional, so by Proposition 29.13, S_1^\perp has finite codimension. Since $S_2 \cap S_1^\perp = (0)$, and since any supplement of S_1^\perp has finite dimension, we must have

$$\dim(S_2) \leq \text{codim}(S_1^\perp) = \dim(S_1).$$

By a similar argument, $\dim(S_1) \leq \dim(S_2)$, so we have

$$\dim(S_1) = \dim(S_2).$$

By Proposition 29.29(1), we conclude that $S = S_1 + S_2$ is nondegenerate.

By Proposition 29.21, the subspace $N = S^\perp = (S_1 + S_2)^\perp$ is nondegenerate. Since $U_1 = U \oplus S_1$, $U_2 = U \oplus S_2$, and U_1, U_2 are totally isotropic, U is orthogonal to S_1 and to S_2 , so $U \subseteq N$. Since U is totally isotropic, by Proposition 29.30 applied to N , there is a totally isotropic subspace W of N such that $\dim(W) = \dim(U)$, $U \cap W = (0)$, and $U + W$ is nondegenerate. Consequently, (d) is satisfied by W .

To satisfy (a) and (b), we pick D to be the orthogonal of $U \oplus W$ in N . Then, $N = (U \oplus W) \overset{\perp}{\oplus} D$ and $E = S \overset{\perp}{\oplus} N$, so $E = S \overset{\perp}{\oplus} (U \oplus W) \overset{\perp}{\oplus} D$.

As to (c), since D is orthogonal $U \oplus W$, D is orthogonal to U , and since $D \subseteq N$ and N is orthogonal to $S_1 + S_2$, D is orthogonal to S_1 , so D is orthogonal to $U_1 = U \oplus S_1$. If $y \in D$

is any isotropic vector, since $y \in U_1^\perp$, by a previous remark, $y \in U_1$, so $y \in D \cap U_1$. But, $D \subseteq N$ with $N \cap (S_1 + S_2) = (0)$, and $D \cap (U + W) = (0)$, so $D \cap (U + S_1) = D \cap U_1 = (0)$, which yields $y = 0$. The statements about dimensions are easily obtained. \square

Finally, Theorem 29.33 yields the strong form of the Witt decomposition in which W is anisotropic. Given any matrix $A \in M_n(K)$, we say that A is *definite* if $x^\top A x \neq 0$ for all $x \in K^n$.

Theorem 29.34. *Let φ be an ϵ -Hermitian form on E which is nondegenerate and satisfies property (T).*

- (1) *Any two totally isotropic maximal spaces of finite dimension have the same dimension.*
- (2) *For any totally isotropic maximal subspace U of finite dimension $r \geq 1$, there is another totally isotropic maximal subspace U' of dimension r such that $U \cap U' = (0)$, and $U \oplus U'$ is nondegenerate. Furthermore, if $D = (U \oplus U')^\perp$, then (U, U', D) is a Witt decomposition of E ; that is, there are no nonzero isotropic vectors in D (D is anisotropic).*
- (3) *If E has finite dimension $n \geq 1$ and there is some nonzero isotropic vector for φ (E is not anisotropic), then E has a nontrivial Witt decomposition (U, U', D) as in (2). There is a basis of E such that*

- (a) *if φ is alternating ($\epsilon = -1$ and $\lambda = \bar{\lambda}$ for all $\lambda \in K$), then $n = 2m$ and φ is represented by a matrix of the form*

$$\begin{pmatrix} 0 & I_m \\ -I_m & 0 \end{pmatrix}$$

- (b) *if φ is symmetric ($\epsilon = +1$ and $\lambda = \bar{\lambda}$ for all $\lambda \in K$), then φ is represented by a matrix of the form*

$$\begin{pmatrix} 0 & I_r & 0 \\ I_r & 0 & 0 \\ 0 & 0 & P \end{pmatrix},$$

where either $n = 2r$ and P does not occur, or $n > 2r$ and P is a definite symmetric matrix.

- (c) *if φ is ϵ -Hermitian (the involutive automorphism $\lambda \mapsto \bar{\lambda}$ is not the identity), then φ is represented by a matrix of the form*

$$\begin{pmatrix} 0 & I_r & 0 \\ \epsilon I_r & 0 & 0 \\ 0 & 0 & P \end{pmatrix},$$

where either $n = 2r$ and P does not occur, or $n > 2r$ and P is a definite matrix such that $P^ = \epsilon P$.*

Proof. Part (1) follows from Theorem 29.33. By Proposition 29.30, we obtain a totally isotropic subspace U' of dimension r such that $U \cap U' = (0)$. By applying Theorem 29.33 to $U_1 = U$ and $U_2 = U'$, we get $U = W = (0)$, which proves (2). Part (3) is an immediate consequence of (2). \square

As a consequence of Theorem 29.34, we make the following definition.

Definition 29.19. Let E be a vector space of finite dimension n , and let φ be an ϵ -Hermitian form on E which is nondegenerate and satisfies property (T). The *index* (or *Witt index*) ν of φ , is the common dimension of all totally isotropic maximal subspaces of E . We have $2\nu \leq n$.

Neutral forms only exist if n is even, in which case, $\nu = n/2$. Forms of index $\nu = 0$ have no nonzero isotropic vectors. When $K = \mathbb{R}$, this is satisfied by positive definite or negative definite symmetric forms. When $K = \mathbb{C}$, this is satisfied by positive definite or negative definite Hermitian forms. The vector space of a neutral Hermitian form ($\epsilon = +1$) is an Artinian space, and the vector space of a neutral alternating form is a hyperbolic space.

If the field K is algebraically closed, we can describe all nondegenerate quadratic forms.

Proposition 29.35. *If K is algebraically closed and E has dimension n , then for every nondegenerate quadratic form Φ , there is a basis (e_1, \dots, e_n) such that Φ is given by*

$$\Phi\left(\sum_{i=1}^n x_i e_i\right) = \begin{cases} \sum_{i=1}^m x_i x_{m+i} & \text{if } n = 2m \\ \sum_{i=1}^m x_i x_{m+i} + x_{2m+1}^2 & \text{if } n = 2m + 1. \end{cases}$$

Proof. We work with the polar form φ of Φ . Let U_1 and U_2 be some totally isotropic subspaces such that $U_1 \cap U_2 = (0)$ given by Theorem 29.34, and let q be their common dimension. Then, $W = U = (0)$. Since we can pick bases (e_1, \dots, e_q) in U_1 and (e_{q+1}, \dots, e_{2q}) in U_2 such that $\varphi(e_i, e_{i+q}) = 0$, for $i, j = 1, \dots, q$, it suffices to prove that $\dim(D) \leq 1$. If $x, y \in D$ with $x \neq 0$, from the identity

$$\Phi(y - \lambda x) = \Phi(y) - \lambda\varphi(x, y) + \lambda^2\Phi(x)$$

and the fact that $\Phi(x) \neq 0$ since $x \in D$ and $x \neq 0$, we see that the equation $\Phi(y - \lambda x) = 0$ has at least one solution. Since $\Phi(z) \neq 0$ for every nonzero $z \in D$, we get $y = \lambda x$, and thus $\dim(D) \leq 1$, as claimed. \square

Proposition 29.35 shows that for every nondegenerate quadratic form Φ over an algebraically closed field, if $\dim(E) = 2m$ or $\dim(E) = 2m + 1$ with $m \geq 1$, then Φ has some nonzero isotropic vector.

29.8 Symplectic Groups

In this section, we are dealing with a nondegenerate alternating form φ on a vector space E of dimension n . As we saw earlier, n must be even, say $n = 2m$. By Theorem 29.24, there is a direct sum decomposition of E into pairwise orthogonal subspaces

$$E = W_1 \overset{\perp}{\oplus} \cdots \overset{\perp}{\oplus} W_m,$$

where each W_i is a hyperbolic plane. Each W_i has a basis (u_i, v_i) , with $\varphi(u_i, u_i) = \varphi(v_i, v_i) = 0$ and $\varphi(u_i, v_i) = 1$, for $i = 1, \dots, m$. In the basis

$$(u_1, \dots, u_m, v_1, \dots, v_m),$$

φ is represented by the matrix

$$J_{m,m} = \begin{pmatrix} 0 & I_m \\ -I_m & 0 \end{pmatrix}.$$

The symplectic group $\mathbf{Sp}(2m, K)$ is the group of isometries of φ . The maps in $\mathbf{Sp}(2m, K)$ are called *symplectic* maps. With respect to the above basis, $\mathbf{Sp}(2m, K)$ is the group of $2m \times 2m$ matrices A such that

$$A^\top J_{m,m} A = J_{m,m}.$$

Matrices satisfying the above identity are called *symplectic* matrices. In this section, we show that $\mathbf{Sp}(2m, K)$ is a subgroup of $\mathbf{SL}(2m, K)$ (that is, $\det(A) = +1$ for all $A \in \mathbf{Sp}(2m, K)$), and we show that $\mathbf{Sp}(2m, K)$ is generated by special linear maps called *symplectic transvections*.

First, we leave it as an easy exercise to show that $\mathbf{Sp}(2, K) = \mathbf{SL}(2, K)$. The reader should also prove that $\mathbf{Sp}(2m, K)$ has a subgroup isomorphic to $\mathbf{GL}(m, K)$.

Next we characterize the symplectic maps f that leave fixed every vector in some given hyperplane H , that is,

$$f(v) = v \quad \text{for all } v \in H.$$

Since φ is nondegenerate, by Proposition 29.22, the orthogonal H^\perp of H is a line (that is, $\dim(H^\perp) = 1$). For every $u \in E$ and every $v \in H$, since f is an isometry and $f(v) = v$ for all $v \in H$, we have

$$\begin{aligned} \varphi(f(u) - u, v) &= \varphi(f(u), v) - \varphi(u, v) \\ &= \varphi(f(u), v) - \varphi(f(u), f(v)) \\ &= \varphi(f(u), v - f(v))) \\ &= \varphi(f(u), 0) = 0, \end{aligned}$$

which shows that $f(u) - u \in H^\perp$ for all $u \in E$. Therefore, $f - \text{id}$ is a linear map from E into the line H^\perp whose kernel contains H , which means that there is some nonzero vector $w \in H^\perp$ and some linear form ψ such that

$$f(u) = u + \psi(u)w, \quad u \in E.$$

Since f is an isometry, we must have $\varphi(f(u), f(v)) = \varphi(u, v)$ for all $u, v \in E$, which means that

$$\begin{aligned}\varphi(u, v) &= \varphi(f(u), f(v)) \\ &= \varphi(u + \psi(u)w, v + \psi(v)w) \\ &= \varphi(u, v) + \psi(u)\varphi(w, v) + \psi(v)\varphi(u, w) + \psi(u)\psi(v)\varphi(w, w) \\ &= \varphi(u, v) + \psi(u)\varphi(w, v) - \psi(v)\varphi(w, u),\end{aligned}$$

which yields

$$\psi(u)\varphi(w, v) = \psi(v)\varphi(w, u) \quad \text{for all } u, v \in E.$$

Since φ is nondegenerate, we can pick some v_0 such that $\varphi(w, v_0) \neq 0$, and we get $\psi(u)\varphi(w, v_0) = \psi(v_0)\varphi(w, u)$ for all $u \in E$; that is,

$$\psi(u) = \lambda\varphi(w, u) \quad \text{for all } u \in E,$$

for some $\lambda \in K$. Therefore, f is of the form

$$f(u) = u + \lambda\varphi(w, u)w, \quad \text{for all } u \in E.$$

It is also clear that every f of the above form is a symplectic map. If $\lambda = 0$, then $f = \text{id}$. Otherwise, if $\lambda \neq 0$, then $f(u) = u$ iff $\varphi(w, u) = 0$ iff $u \in (Kw)^\perp = H$, where H is a hyperplane. Thus, f fixes every vector in the hyperplane H . Note that since φ is alternating, $\varphi(w, w) = 0$, which means that $w \in H$.

In summary, we have characterized all the symplectic maps that leave every vector in some hyperplane fixed, and we make the following definition.

Definition 29.20. Given a nondegenerate alternating form φ on a space E , a *symplectic transvection (of direction w)* is a linear map f of the form

$$f(u) = u + \lambda\varphi(w, u)w, \quad \text{for all } u \in E,$$

for some nonzero $w \in E$ and some $\lambda \in K$. If $\lambda \neq 0$, the subspace of vectors left fixed by f is the hyperplane $H = (Kw)^\perp$. The map f is also denoted $\tau_{w,\lambda}$.

Observe that

$$\tau_{w,\lambda} \circ \tau_{w,\mu} = \tau_{w,\lambda+\mu}$$

and $\tau_{w,\lambda} = \text{id}$ iff $\lambda = 0$. The above shows that $\det(\tau_{w,\lambda}) = 1$, since when $\lambda \neq 0$, we have $\tau_{w,\lambda} = (\tau_{w,\lambda/2})^2$.

Our next goal is to show that if u and v are any two nonzero vectors in E , then there is a simple symplectic map f such that $f(u) = v$.

Proposition 29.36. *Given any two nonzero vectors $u, v \in E$, there is a symplectic map f such that $f(u) = v$, and f is either a symplectic transvection, or the composition of two symplectic transvections.*

Proof. There are two cases.

Case 1. $\varphi(u, v) \neq 0$.

In this case, $u \neq v$, since $\varphi(u, u) = 0$. Let us look for a symplectic transvection of the form $\tau_{v-u,\lambda}$. We want

$$v = u + \lambda\varphi(v - u, u)(v - u) = u + \lambda\varphi(v, u)(v - u),$$

which yields

$$(\lambda\varphi(v, u) - 1)(v - u) = 0.$$

Since $\varphi(u, v) \neq 0$ and $\varphi(v, u) = -\varphi(u, v)$, we can pick $\lambda = \varphi(v, u)^{-1}$ and $\tau_{v-u,\lambda}$ maps u to v .

Case 2. $\varphi(u, v) = 0$.

If $u = v$, use $\tau_{u,0} = \text{id}$. Now, assume $u \neq v$. We claim that it is possible to pick some $w \in E$ such that $\varphi(u, w) \neq 0$ and $\varphi(v, w) \neq 0$. Indeed, if $(Ku)^\perp = (Kv)^\perp$, then pick any nonzero vector w not in the hyperplane $(Ku)^\perp$. Otherwise, $(Ku)^\perp$ and $(Kv)^\perp$ are two distinct hyperplanes, so neither is contained in the other (they have the same dimension), so pick any nonzero vector w_1 such that $w_1 \in (Ku)^\perp$ and $w_1 \notin (Kv)^\perp$, and pick any nonzero vector w_2 such that $w_2 \in (Kv)^\perp$ and $w_2 \notin (Ku)^\perp$. If we let $w = w_1 + w_2$, then $\varphi(u, w) = \varphi(u, w_2) \neq 0$, and $\varphi(v, w) = \varphi(v, w_1) \neq 0$. From case 1, we have some symplectic transvection τ_{w-u,λ_1} such that $\tau_{w-u,\lambda_1}(u) = w$, and some symplectic transvection τ_{v-w,λ_2} such that $\tau_{v-w,\lambda_2}(w) = v$, so the composition $\tau_{v-w,\lambda_2} \circ \tau_{w-u,\lambda_1}$ maps u to v . \square

Next, we would like to extend Proposition 29.36 to two hyperbolic planes W_1 and W_2 .

Proposition 29.37. *Given any two hyperbolic planes W_1 and W_2 given by bases (u_1, v_1) and (u_2, v_2) (with $\varphi(u_i, u_i) = \varphi(v_i, v_i) = 0$ and $\varphi(u_i, v_i) = 1$, for $i = 1, 2$), there is a symplectic map f such that $f(u_1) = u_2$, $f(v_1) = v_2$, and f is the composition of at most four symplectic transvections.*

Proof. From Proposition 29.36, we can map u_1 to u_2 , using a map f which is the composition of at most two symplectic transvections. Say $v_3 = f(v_1)$. We claim that there is a map g such that $g(u_2) = u_2$ and $g(v_3) = v_2$, and g is the composition of at most two symplectic transvections. If so, $g \circ f$ maps the pair (u_1, v_1) to the pair (u_2, v_2) , and $g \circ f$ consists of at most four symplectic transvections. Thus, we need to prove the following claim:

Claim. If (u, v) and (u, v') are hyperbolic bases determining two hyperbolic planes, then there is a symplectic map g such that $g(u) = u$, $g(v) = v'$, and g is the composition of at most two symplectic transvections. There are two cases.

Case 1. $\varphi(v, v') \neq 0$.

In this case, there is a symplectic transvection $\tau_{v'-v,\lambda}$ such that $\tau_{v'-v,\lambda}(v) = v'$. We also have

$$\varphi(u, v' - v) = \varphi(u, v') - \varphi(u, v) = 1 - 1 = 0.$$

Therefore, $\tau_{v'-v,\lambda}(u) = u$, and $g = \tau_{v'-v,\lambda}$ does the job.

Case 2. $\varphi(v, v') = 0$.

First, check that $(u, u + v)$ is also hyperbolic basis. Furthermore,

$$\varphi(v, u + v) = \varphi(v, u) + \varphi(v, v) = \varphi(v, u) = -1 \neq 0.$$

Thus, there is a symplectic transvection τ_{v,λ_1} such that $\tau_{u,\lambda_1}(v) = u + v$ and $\tau_{u,\lambda_1}(u) = u$. We also have

$$\varphi(u + v, v') = \varphi(u, v') + \varphi(v, v') = \varphi(u, v') = 1 \neq 0,$$

so there is a symplectic transvection $\tau_{v'-u-v,\lambda_2}$ such that $\tau_{v'-u-v,\lambda_2}(u + v) = v'$. Since

$$\varphi(u, v' - u - v) = \varphi(u, v') - \varphi(u, u) - \varphi(u, v) = 1 - 0 - 1 = 0,$$

we have $\tau_{v'-u-v,\lambda_2}(u) = u$. Then, the composition $g = \tau_{v'-u-v,\lambda_2} \circ \tau_{u,\lambda_1}$ is such that $g(u) = u$ and $g(v) = v'$. \square

We will use Proposition 29.37 in an inductive argument to prove that the symplectic transvections generate the symplectic group. First, make the following observation: If U is a nondegenerate subspace of E , so that

$$E = U \overset{\perp}{\oplus} U^\perp,$$

and if τ is a transvection of H^\perp , then we can form the linear map $\text{id}_U \overset{\perp}{\oplus} \tau$ whose restriction to U is the identity and whose restriction to U^\perp is τ , and $\text{id}_U \overset{\perp}{\oplus} \tau$ is a transvection of E .

Theorem 29.38. *The symplectic group $\mathbf{Sp}(2m, K)$ is generated by the symplectic transvections. For every transvection $f \in \mathbf{Sp}(2m, K)$, we have $\det(f) = 1$.*

Proof. Let G be the subgroup of $\mathbf{Sp}(2m, K)$ generated by the transvections. We need to prove that $G = \mathbf{Sp}(2m, K)$. Let $(u_1, v_1, \dots, u_m, v_m)$ be a symplectic basis of E , and let $f \in \mathbf{Sp}(2m, K)$ be any symplectic map. Then, f maps $(u_1, v_1, \dots, u_m, v_m)$ to another symplectic basis $(u'_1, v'_1, \dots, u'_m, v'_m)$. If we prove that there is some $g \in G$ such that $g(u_i) = u'_i$ and $g(v_i) = v'_i$ for $i = 1, \dots, m$, then $f = g$ and $G = \mathbf{Sp}(2m, K)$.

We use induction on i to prove that there is some $g_i \in G$ so that g_i maps $(u_1, v_1, \dots, u_i, v_i)$ to $(u'_1, v'_1, \dots, u'_i, v'_i)$.

The base case $i = 1$ follows from Proposition 29.37.

For the induction step, assume that we have some $g_i \in G$ mapping $(u_1, v_1, \dots, u_i, v_i)$ to $(u'_1, v'_1, \dots, u'_i, v'_i)$, and let $(u''_{i+1}, v''_{i+1}, \dots, u''_m, v''_m)$ be the image of $(u_{i+1}, v_{i+1}, \dots, u_m, v_m)$ by g_i . If U is the subspace spanned by $(u'_1, v'_1, \dots, u'_m, v'_m)$, then each hyperbolic plane W'_{i+k} given by (u'_{i+k}, v'_{i+k}) and each hyperbolic plane W''_{i+k} given by (u''_{i+k}, v''_{i+k}) belongs to

U^\perp . Using the remark before the theorem and Proposition 29.37, we can find a transvection τ mapping W''_{i+1} onto W'_{i+1} and leaving every vector in U fixed. Then, $\tau \circ g_i$ maps $(u_1, v_1, \dots, u_{i+1}, v_{i+1})$ to $(u'_1, v'_1, \dots, u'_{i+1}, v'_{i+1})$, establishing the induction step.

For the second statement, since we already proved that every transvection has a determinant equal to $+1$, this also holds for any composition of transvections in G , and since $G = \mathbf{Sp}(2m, K)$, we are done. \square

It can also be shown that the center of $\mathbf{Sp}(2m, K)$ is reduced to the subgroup $\{\text{id}, -\text{id}\}$. The *projective symplectic group* $\mathbf{PSp}(2m, K)$ is the quotient group $\mathbf{PSp}(2m, K)/\{\text{id}, -\text{id}\}$. All symplectic projective groups are simple, except $\mathbf{PSp}(2, \mathbb{F}_2)$, $\mathbf{PSp}(2, \mathbb{F}_3)$, and $\mathbf{PSp}(4, \mathbb{F}_2)$, see Grove [83].

The orders of the symplectic groups over finite fields can be determined. For details, see Artin [6], Jacobson [98] and Grove [83].

An interesting property of symplectic spaces is that the determinant of a skew-symmetric matrix B is the square of some polynomial $\text{Pf}(B)$ called the *Pfaffian*; see Jacobson [98] and Artin [6]. We leave considerations of the Pfaffian to the exercises.

We now take a look at the orthogonal groups.

29.9 Orthogonal Groups and the Cartan–Dieudonné Theorem

In this section we are dealing with a nondegenerate symmetric bilinear form φ over a finite-dimensional vector space E of dimension n over a field of characteristic not equal to 2. Recall that the orthogonal group $\mathbf{O}(\varphi)$ is the group of isometries of φ ; that is, the group of linear maps $f: E \rightarrow E$ such that

$$\varphi(f(u), f(v)) = \varphi(u, v) \quad \text{for all } u, v \in E.$$

The elements of $\mathbf{O}(\varphi)$ are also called *orthogonal transformations*. If M is the matrix of φ in any basis, then a matrix A represents an orthogonal transformation iff

$$A^\top M A = M.$$

Since φ is nondegenerate, M is invertible, so we see that $\det(A) = \pm 1$. The subgroup

$$\mathbf{SO}(\varphi) = \{f \in \mathbf{O}(\varphi) \mid \det(f) = 1\}$$

is called the *special orthogonal group* (of φ), and its members are called *rotations* (or *proper orthogonal transformations*). Isometries $f \in \mathbf{O}(\varphi)$ such that $\det(f) = -1$ are called *improper orthogonal transformations*, or sometimes *reversions*.

If H is any nondegenerate hyperplane in E , then $D = H^\perp$ is a nondegenerate line and we have

$$E = H \overset{\perp}{\oplus} H^\perp.$$

For any nonzero vector $u \in D = H^\perp$ Consider the map τ_u given by

$$\tau_u(v) = v - 2 \frac{\varphi(v, u)}{\varphi(u, u)} u \quad \text{for all } v \in E.$$

If we replace u by λu with $\lambda \neq 0$, we have

$$\tau_{\lambda u}(v) = v - 2 \frac{\varphi(v, \lambda u)}{\varphi(\lambda u, \lambda u)} \lambda u = v - 2 \frac{\lambda \varphi(v, u)}{\lambda^2 \varphi(u, u)} \lambda u = v - 2 \frac{\varphi(v, u)}{\varphi(u, u)} u,$$

which shows that τ_u depends only on the line D , and thus only the hyperplane H . Therefore, denote by τ_H the linear map τ_u determined as above by any nonzero vector $u \in H^\perp$. Note that if $v \in H$, then

$$\tau_H(v) = v,$$

and if $v \in D$, then

$$\tau_H(v) = -v.$$

A simple computation shows that

$$\varphi(\tau_H(u), \tau_H(v)) = \varphi(u, v) \quad \text{for all } u, v \in E,$$

so $\tau_H \in \mathbf{O}(\varphi)$, and by picking a basis consisting of u and vectors in H , that $\det(\tau_H) = -1$. It is also clear that $\tau_H^2 = \text{id}$.

Definition 29.21. If H is any nondegenerate hyperplane in E , for any nonzero vector $u \in H^\perp$, the linear map τ_H given by

$$\tau_H(v) = v - 2 \frac{\varphi(v, u)}{\varphi(u, u)} u \quad \text{for all } v \in E$$

is an involutive isometry of E called the *reflection through (or about) the hyperplane H* .

Remarks:

1. It can be shown that if $f \in \mathbf{O}(\varphi)$ leaves every vector in some hyperplane H fixed, then either $f = \text{id}$ or $f = \tau_H$; see Taylor [174] (Chapter 11). Thus, there is no analog to symplectic transvections in the orthogonal group.
2. If $K = \mathbb{R}$ and φ is the usual Euclidean inner product, the matrices corresponding to hyperplane reflections are called *Householder matrices*.

Our goal is to prove that $\mathbf{O}(\varphi)$ is generated by the hyperplane reflections. The following proposition is needed.

Proposition 29.39. *Let φ be a nondegenerate symmetric bilinear form on a vector space E . For any two nonzero vectors $u, v \in E$, if $\varphi(u, u) = \varphi(v, v)$ and $v - u$ is nonisotropic, then the hyperplane reflection $\tau_H = \tau_{v-u}$ maps u to v , with $H = (K(v - u))^\perp$.*

Proof. Since $v - u$ is not isotropic, $\varphi(v - u, v - u) \neq 0$, and we have

$$\begin{aligned}\tau_{v-u}(u) &= u - 2 \frac{\varphi(u, v - u)}{\varphi(v - u, v - u)}(v - u) \\ &= u - 2 \frac{\varphi(u, v) - \varphi(u, u)}{\varphi(v, v) - 2\varphi(u, v) + \varphi(u, u)}(v - u) \\ &= u - \frac{2(\varphi(u, v) - \varphi(u, u))}{2(\varphi(u, u) - 2\varphi(u, v))}(v - u) \\ &= v,\end{aligned}$$

which proves the proposition. \square

We can now obtain a cheap version of the Cartan–Dieudonné theorem.

Theorem 29.40. (*Cartan–Dieudonné, weak form*) *Let φ be a nondegenerate symmetric bilinear form on a K -vector space E of dimension n ($\text{char}(K) \neq 2$). Then, every isometry $f \in \mathbf{O}(\varphi)$ with $f \neq \text{id}$ is the composition of at most $2n - 1$ hyperplane reflections.*

Proof. We proceed by induction on n . For $n = 0$, this is trivial (since $\mathbf{O}(\varphi) = \{\text{id}\}$).

Next, assume that $n \geq 1$. Since φ is nondegenerate, we know that there is some non-isotropic vector $u \in E$. There are three cases.

Case 1. $f(u) = u$.

Since φ is nondegenerate and u is nonisotropic, the hyperplane $H = (Ku)^\perp$ is nondegenerate, $E = H \overset{\perp}{\oplus} Ku$, and since $f(u) = u$, we must have $f(H) = H$. The restriction f' of f to H is an isometry of H . By the induction hypothesis, we can write

$$f' = \tau'_k \circ \cdots \circ \tau'_1,$$

where τ_i is some hyperplane reflection about a hyperplane L_i in H , with $k \leq 2n - 3$. We can extend each τ'_i to a reflection τ_i about the hyperplane $L_i \overset{\perp}{\oplus} Ku$ so that $\tau_i(u) = u$, and clearly,

$$f = \tau_k \circ \cdots \circ \tau_1.$$

Case 2. $f(u) = -u$.

If τ is the hyperplane reflection about the hyperplane $H = (Ku)^\perp$, then $g = \tau \circ f$ is an isometry of E such that $g(u) = u$, and we are back to Case (1). Since $\tau^2 = 1$ We obtain

$$f = \tau \circ \tau_k \circ \cdots \circ \tau_1$$

where τ and the τ_i are hyperplane reflections, with $k \geq 2n - 3$, and we get a total of $2n - 2$ hyperplane reflections.

Case 3. $f(u) \neq u$ and $f(u) \neq -u$.

Note that $f(u) - u$ and $f(u) + u$ are orthogonal, since

$$\begin{aligned}\varphi(f(u) - u, f(u) + u) &= \varphi(f(u), f(u)) + \varphi(f(u), u) - \varphi(u, f(u)) - \varphi(u, u) \\ &= \varphi(u, u) - \varphi(u, u) = 0.\end{aligned}$$

We also have

$$\begin{aligned}\varphi(u, u) &= \varphi((f(u) + u - (f(u) - u))/2, (f(u) + u - (f(u) - u))/2) \\ &= \frac{1}{4}\varphi(f(u) + u, f(u) + u) + \frac{1}{4}\varphi(f(u) - u, f(u) - u),\end{aligned}$$

so $f(u) + u$ and $f(u) - u$ cannot be both isotropic, since u is not isotropic.

If $f(u) - u$ is not isotropic, then the reflection $\tau_{f(u)-u}$ is such that

$$\tau_{f(u)-u}(u) = f(u),$$

and since $\tau_{f(u)-u}^2 = \text{id}$, if $g = \tau_{f(u)-u} \circ f$, then $g(u) = u$, and we are back to case (1). We obtain

$$f = \tau_{f(u)-u} \circ \tau_k \circ \cdots \circ \tau_1$$

where $\tau_{f(u)-u}$ and the τ_i are hyperplane reflections, with $k \geq 2n - 3$, and we get a total of $2n - 2$ hyperplane reflections.

If $f(u) + u$ is not isotropic, then the reflection $\tau_{f(u)+u}$ is such that

$$\tau_{f(u)+u}(u) = -f(u),$$

and since $\tau_{f(u)+u}^2 = \text{id}$, if $g = \tau_{f(u)+u} \circ f$, then $g(u) = -u$, and we are back to case (2). We obtain

$$f = \tau_{f(u)-u} \circ \tau \circ \tau_k \circ \cdots \circ \tau_1$$

where $\tau, \tau_{f(u)-u}$ and the τ_i are hyperplane reflections, with $k \geq 2n - 3$, and we get a total of $2n - 1$ hyperplane reflections. This proves the induction step. \square

The bound $2n - 1$ is not optimal. The strong version of the Cartan–Dieudonné theorem says that at most n reflections are needed, but the proof is harder. Here is a neat proof due to E. Artin (see [6], Chapter III, Section 4).

Case 1 remains unchanged. Case 2 is slightly different: $f(u) - u \neq 0$ is not isotropic. Since $\varphi(f(u) + u, f(u) - u) = 0$, as in the first subcase of Case (3), $g = \tau_{f(u)-u} \circ f$ is such that $g(u) = u$ and we are back to Case 1. This only costs one more reflection.

The new (bad) case is:

Case 3'. $f(u) - u$ is nonzero and isotropic for all nonisotropic $u \in E$. In this case, what saves us is that E must be an Artinian space of dimension $n = 2m$ and that f must be a rotation ($f \in \mathbf{SO}(\varphi)$).

If we accept this fact proved in Proposition 29.43 then pick any hyperplane reflection τ . Then, since f is a rotation, $g = \tau \circ f$ is *not* a rotation because $\det(g) = \det(\tau)\det(f) = (-1)(+1) = -1$, so $g(u) - u$ is either 0 or not isotropic for some nonisotropic $u \in E$ (otherwise, g would be a rotation), we are back to either Case 1 or Case 2, and using the induction hypothesis, we get

$$\tau \circ f = \tau_k \circ \dots, \tau_1,$$

where each τ_i is a hyperplane reflection, and $k \leq 2m$. Since $\tau \circ f$ is not a rotation, actually $k \leq 2m - 1$, and then $f = \tau \circ \tau_k \circ \dots, \tau_1$, the composition of at most $k + 1 \leq 2m$ hyperplane reflections.

Therefore, except for the fact that in Case 3', E must be an Artinian space of dimension $n = 2m$ and that f must be a rotation, which has not been proven yet, we proved the following theorem.

Theorem 29.41. (*Cartan–Dieudonné, strong form*) *Let φ be a nondegenerate symmetric bilinear form on a K -vector space E of dimension n ($\text{char}(K) \neq 2$). Then, every isometry $f \in \mathbf{O}(\varphi)$ with $f \neq \text{id}$ is the composition of at most n hyperplane reflections.*

To fill in the gap, we need two propositions.

Proposition 29.42. *Let (E, φ) be an Artinian space of dimension $2m$, and let U be a totally isotropic subspace of dimension m . For any isometry $f \in \mathbf{O}(\varphi)$, if $f(U) = U$, then $\det(f) = 1$ (f is a rotation).*

Proof. We know that we can find a basis $(u_1, \dots, u_m, v_1, \dots, v_m)$ of E such (u_1, \dots, u_m) is a basis of U and φ is represented by the matrix

$$\begin{pmatrix} 0 & I_m \\ I_m & 0 \end{pmatrix}.$$

Since $f(U) = U$, the matrix representing f is of the form

$$A = \begin{pmatrix} B & C \\ 0 & D \end{pmatrix}.$$

The condition $A^\top A_{m,m} A = A_{m,m}$ translates as

$$\begin{pmatrix} B^\top & 0 \\ C^\top & D^\top \end{pmatrix} \begin{pmatrix} 0 & I_m \\ I_m & 0 \end{pmatrix} \begin{pmatrix} B & C \\ 0 & D \end{pmatrix} = \begin{pmatrix} 0 & I_m \\ I_m & 0 \end{pmatrix}$$

that is,

$$\begin{pmatrix} B^\top & 0 \\ C^\top & D^\top \end{pmatrix} \begin{pmatrix} 0 & D \\ B & C \end{pmatrix} = \begin{pmatrix} 0 & B^\top D \\ D^\top B & C^\top D + D^\top C \end{pmatrix} = \begin{pmatrix} 0 & I_m \\ I_m & 0 \end{pmatrix},$$

which implies that $B^\top D = I$, and so

$$\det(A) = \det(B) \det(D) = \det(B^\top) \det(D) = \det(B^\top D) = \det(I) = 1,$$

as claimed \square

Proposition 29.43. *Let φ be a nondegenerate symmetric bilinear form on a space E of dimension n , and let f be any isometry $f \in \mathbf{O}(\varphi)$ such that $f(u) - u$ is nonzero and isotropic for every nonisotropic vector $u \in E$. Then, E is an Artinian space of dimension $n = 2m$, and f is a rotation ($f \in \mathbf{SO}(\varphi)$).*

Proof. We follow E. Artin's proof (see [6], Chapter III, Section 4). First, consider the case $n = 2$. Since we are assuming that E has some nonzero isotropic vector, by Proposition 29.26, E is an Artinian plane and there is a basis in which φ is represented by the matrix

$$\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix},$$

we have $\varphi((x_1, x_2), (x_1, x_2)) = 2x_1x_2$, and the matrices representing isometries are of the form

$$\begin{pmatrix} \lambda & 0 \\ 0 & \lambda^{-1} \end{pmatrix} \quad \text{or} \quad \begin{pmatrix} 0 & \lambda \\ \lambda^{-1} & 0 \end{pmatrix}, \quad \lambda \in K - \{0\}.$$

In the second case,

$$\begin{pmatrix} 0 & \lambda \\ \lambda^{-1} & 0 \end{pmatrix} \begin{pmatrix} \lambda \\ 1 \end{pmatrix} = \begin{pmatrix} \lambda \\ 1 \end{pmatrix},$$

but $u = (\lambda, 1)$ is a nonisotropic vector such that $f(u) - u = 0$. Therefore, we must be in the first case, and $\det(f) = +1$.

Let us now assume that $n \geq 3$. We are going to prove that $f(y) - y$ is isotropic for all nonzero isotropic vectors y . Let y be any nonzero isotropic vector. Since $n \geq 3$, the orthogonal space $(Ky)^\perp$ has dimension at least 2, and we know that $\text{rad}(Ky) = \text{rad}((Ky)^\perp)$, a space of dimension at most 1, which implies that $(Ky)^\perp$ contains some nonisotropic vector, say x . We have $\varphi(x, y) = 0$, so $\varphi(x + \epsilon y, x + \epsilon y) = \varphi(x, x) \neq 0$, for $\epsilon = \pm 1$. Then, by hypothesis, the vectors $f(x) - x, f(x + y) - (x + y) = f(x) - x + (f(y) - y)$, and $f(x - y) - (x - y) = f(x) - x - (f(y) - y)$ are isotropic. The last two vectors can be written as $f(x) - x + \epsilon(f(y) - y)$ with $\epsilon = \pm 1$, so we have

$$\begin{aligned} 0 &= \varphi(f(x) - x + \epsilon(f(y) - y), f(x) - x + \epsilon(f(y) - y)) \\ &= 2\epsilon\varphi(f(x) - x, f(y) - y) + \epsilon^2\varphi(f(y) - y, f(y) - y). \end{aligned}$$

If we write the two equations corresponding to $\epsilon = \pm 1$, and then add them up, we get

$$\varphi(f(y) - y, f(y) - y) = 0.$$

This proves that $f(y) - y$ is isotropic for any nonzero isotropic vector y . Since by hypothesis $f(u) - u$ is isotropic for every nonisotropic vector u , we proved that $f(u) - u$ is isotropic for every $u \in E$. If we let $W = \text{Im}(f - \text{id})$, then every vector in W is isotropic, and thus W is totally isotropic (recall that we assumed that $\text{char}(K) \neq 2$, so φ is determined by Φ). For any $u \in E$ and any $v \in W^\perp$, since W is totally isotropic, we have

$$\varphi(f(u) - u, f(v) - v) = 0,$$

and since $f(u) - u \in W$ and $v \in W^\perp$, we have $\varphi(f(u) - u, v) = 0$, and so

$$\begin{aligned} 0 &= \varphi(f(u) - u, f(v) - v) \\ &= \varphi(f(u), f(v)) - \varphi(u, f(v)) - \varphi(f(u) - u, v) \\ &= \varphi(u, v) - \varphi(u, f(v)) \\ &= \varphi(u, v - f(v)), \end{aligned}$$

for all $u \in E$. Since φ is nonsingular, this means that $f(v) = v$, for all $v \in W^\perp$. However, by hypothesis, no nonisotropic vector is left fixed, which implies that W^\perp is also totally isotropic. In summary, we proved that $W \subseteq W^\perp$ and $W^\perp \subseteq W^{\perp\perp} = W$, that is,

$$W = W^\perp.$$

Since, $\dim(W) + \dim(W^\perp) = n$, we conclude that W is a totally isotropic subspace of E such that

$$\dim(W) = n/2.$$

By Proposition 29.29, the space E is an Artinian space of dimension $n = 2m$. Since $W = W^\perp$ and $f(W) = W$, by Proposition 29.42, the isometry f is a rotation. \square

Remarks:

1. Another way to finish the proof of Proposition 29.43 is to prove that if f is an isometry, then

$$\text{Ker}(f - \text{id}) = (\text{Im}(f - \text{id}))^\perp.$$

After having proved that $W = \text{Im}(f - \text{id})$ is totally isotropic, we get

$$\text{Ker}(f - \text{id}) = \text{Im}(f - \text{id}),$$

which implies that $(f - \text{id})^2 = 0$. From this, we deduce that $\det(f) = 1$. For details, see Jacobson [98] (Chapter 6, Section 6).

2. If $f = \tau_{H_k} \circ \cdots \circ \tau_{H_1}$, where the H_i are hyperplanes, then it can be shown that

$$\dim(H_1 \cap H_2 \cap \cdots \cap H_s) \geq n - s.$$

Now, since each H_i is left fixed by τ_{H_i} , we see that every vector in $H_1 \cap \cdots \cap H_s$ is left fixed by f . In particular, if $s < n$, then f has some nonzero fixed point. As a consequence, an isometry without fixed points requires n hyperplane reflections.

29.10 Witt's Theorem

Witt's theorem was referred to as a “scandal” by Emil Artin. What he meant by this is that one had to wait until 1936 (Witt [190]) to formulate and prove a theorem at once so simple in its statement and underlying concepts, and so useful in various domains (geometry, arithmetic of quadratic forms).¹

Besides Witt's original proof (Witt [190]), Chevalley's proof [37] seems to be the “best” proof that applies to the symmetric as well as the skew-symmetric case. The proof in Bourbaki [24] is based on Chevalley's proof, and so are a number of other proofs. This is the one we follow (slightly reorganized). In the symmetric case, Serre's exposition is hard to beat (see Serre [157], Chapter IV).

The following observation is one of the key ingredients in the proof of Theorem 29.45.

Proposition 29.44. *Given a finite-dimensional space E equipped with an ϵ -Hermitian form φ , if U_1 and U_2 are two subspaces of E such that $U_1 \cap U_2 = (0)$ and if we have metric linear maps $f_1: U_1 \rightarrow E$ and $f_2: U_2 \rightarrow E$ such that*

$$\varphi(f_1(u_1), f_2(u_2)) = \varphi(u_1, u_2) \quad \text{for } u_i \in U_i \ (i = 1, 2), \quad (*)$$

then the linear map $f: U_1 \oplus U_2 \rightarrow E$ given by $f(u_1 + u_2) = f_1(u_1) + f_2(u_2)$ extends f_1 and f_2 and is metric. Furthermore, if f_1 and f_2 are injective, then so is f .

Proof. Indeed, since f_1 and f_2 are metric and using (*), we have

$$\begin{aligned} \varphi(f_1(u_1) + f_2(u_2), f_1(v_1) + f_2(v_2)) &= \varphi(f_1(u_1), f_1(v_1)) + \varphi(f_1(u_1), f_2(v_2)) \\ &\quad + \varphi(f_2(u_2), f_1(v_1)) + \varphi(f_2(u_2), f_2(v_2)) \\ &= \varphi(u_1, v_1) + \varphi(u_1, v_2) + \varphi(u_2, v_1) + \varphi(u_2, v_2) \\ &= \varphi(u_1 + u_2, v_1 + v_2). \end{aligned}$$

Thus f is a metric map extending f_1 and f_2 . □

Theorem 29.45. (Witt, 1936) *Let E and E' be two finite-dimensional spaces respectively equipped with two nondegenerate ϵ -Hermitian forms φ and φ' satisfying condition (T), and assume that there is an isometry between (E, φ) and (E', φ') . For any subspace U of E , every injective metric linear map f from U into E' extends to an isometry from E to E' .*

Proof. Since (E, φ) and (E', φ') are isometric, we may assume that $E' = E$ and $\varphi' = \varphi$ (if $h: E \rightarrow E'$ is an isometry, then $h^{-1} \circ f$ is an injective metric map from U into E . The details are left to the reader).

¹Curiously, some references to Witt's paper claim its date of publication to be 1936, but others say 1937. The answer to this mystery is that Volume 176 of *Crelle Journal* was published in four issues. The cover page of volume 176 mentions the year 1937, but Witt's paper is dated May 1936. This is not the only paper of Witt appearing in this volume!

We proceed by induction on the dimension r of U . Since the proof is quite intricate, we spell out the general plan of attack. For the induction step, we first show that we can reduce the situation to what we call *Case (H)*, namely that the subspace of U left fixed by f is a hyperplane H in U . Then, the set $D = \{f(u) - u \mid u \in U\}$ is a line in U and it turns out that D^\perp is a hyperplane in E . We now introduce *Hypothesis (V)*, which says we can find a nontrivial subspace V of E orthogonal to D and such that $V \cap U = V \cap f(U) = (0)$. We show that if Hypothesis (V) holds, then f can be extended to an isometry of $U \oplus V$. It is then possible to further extend f to an isometry of E .

To prove that Hypothesis (V) holds we consider two cases. In Case (a), we obtain some V such that $E = U \oplus V$ and we are done. In Case (b), we obtain some V such that $D^\perp = U \oplus V$. We are then reduced to the situation where $U = D^\perp$ is a hyperplane in E and f is an isometry of U . To finish the proof we pick any $v \notin U$, so that $E = U \oplus Kv$, and we find some $v_1 \in E$ such that

$$\begin{aligned}\varphi(f(u), v_1) &= \varphi(u, v) \quad \text{for all } u \in U \\ \varphi(v_1, v_1) &= \varphi(v, v).\end{aligned}$$

Then, by Proposition 29.44, we can extend f to a metric map g of $U + Kv = E$ such that $g(v) = v_1$. The argument used to find v_1 makes use of (\dagger) (see below) and is bit tricky. We also makes use of Property (T) in the form of Lemma 29.28.

We now go back to the proof. The case $r = 0$ is trivial. For the induction step, $r \geq 1$ so $U \neq (0)$, and let H be any hyperplane in U . Let $f: U \rightarrow E$ be an injective metric linear map. By the induction hypothesis, the restriction f_0 of f to H extends to an isometry g_0 of E . If g_0 extends f , we are done. Otherwise, H is the subspace of elements of U left fixed by $g_0^{-1} \circ f$. If the theorem holds in this situation, namely the subspace of U left fixed by $g_0^{-1} \circ f$ is a hyperplane H in U , then we have an isometry g_1 of E extending $g_0^{-1} \circ f$, and $g_0 \circ g_1$ is an isometry of E extending f . Therefore, we are reduced to the following situation:

Case (H). The subspace of U left fixed by f is a hyperplane H in U .

In this case, the set $D = \{f(u) - u \mid u \in U\}$ is a line in U (a one-dimensional subspace). For all $u, v \in U$, we have

$$\varphi(f(u), f(v) - v) = \varphi(f(u), f(v)) - \varphi(f(u), v) = \varphi(u, v) - \varphi(f(u), v) = \varphi(u - f(u), v),$$

that is

$$\varphi(f(u), f(v) - v) = \varphi(u - f(u), v) \quad \text{for all } u, v \in U, \tag{**}$$

and if $u \in H$, which means that $f(u) = u$, we get $u \in D^\perp$. Therefore, $H \subseteq D^\perp$. Since φ is nondegenerate, we have $\dim(D) + \dim(D^\perp) = \dim(E)$, and since $\dim(D) = 1$, the subspace D^\perp is a hyperplane in E .

Hypothesis (V). We can find a nontrivial subspace V of E orthogonal to D and such that $V \cap U = V \cap f(U) = (0)$.

Claim. Hypothesis (V) implies that f can be extended to an isometry of $U \oplus V$.

Proof of Claim. If Hypothesis (V) holds, then we have

$$\varphi(f(u), v) = \varphi(u, v) \quad \text{for all } u \in U \text{ and all } v \in V,$$

since $\varphi(f(u), v) - \varphi(u, v) = \varphi(f(u) - u, v) = 0$, with $f(u) - u \in D$ and $v \in V$ orthogonal to D . By Proposition 29.44 with $f_1 = f$ and f_2 the inclusion of V into E , we can extend f to an injective metric map on $U \oplus V$ leaving all vectors in V fixed. In this case, the set $\{f(w) - w \mid w \in U \oplus V\}$ is still the line D . \square

We show below that the fact that f can be extended to $U \oplus V$ implies that f can be extended to the whole of E . There are two cases. In Case (a), $E = U \oplus V$ and we are done. In case (b), $D^\perp = U \oplus V$ where D^\perp is a hyperplane in E and f is an isometry of D^\perp . By a subtle argument, we will show that f can be extended to an isometry of E .

We are reduced to proving that a subspace V as above exists. We distinguish between two cases.

Case (a). $U \not\subseteq D^\perp$.

Proof of Case (a). In this case, formula (**) show that $f(U)$ is not contained in D^\perp (check this!). Consequently,

$$U \cap D^\perp = f(U) \cap D^\perp = H.$$

We can pick V to be any supplement of H in D^\perp , and the above formula shows that $V \cap U = V \cap f(U) = (0)$. Since $U \oplus V$ contains the hyperplane D^\perp (since $D^\perp = H \oplus V$ and $H \subseteq U$), and $U \oplus V \neq D^\perp$ (since U is not contained in D^\perp and $V \subseteq D^\perp$), we must have $E = U \oplus V$, and as we showed as a consequence of hypothesis (V), f can be extended to an isometry of $U \oplus V = E$. \square

Case (b). $U \subseteq D^\perp$.

Proof of Case (b). In this case, formula (**) shows that $f(U) \subseteq D^\perp$ so $U + f(U) \subseteq D^\perp$, and since $D = \{f(u) - u \mid u \in U\}$, we have $D \subseteq D^\perp$; that is, the line D is isotropic.

We show that there exists a subspace V of D^\perp , such that

$$D^\perp = U \oplus V = f(U) \oplus V.$$

Thus, case (b) shows that we are reduced to the situation where $U = D^\perp$ and f is an isometry of U .

If $U = f(U)$ we pick V to be a supplement of U in D^\perp . Otherwise, let $x \in U$ with $x \notin H$, and let $y \in f(U)$ with $y \notin H$. Since $f(H) = H$ (pointwise), f is injective, and H is a hyperplane in U , we have

$$U = H \oplus Kx, \quad f(U) = H \oplus Ky.$$

We claim that $x + y \notin U$. Otherwise, since $y = x + y - x$, with $x + y, x \in U$ and since $y \in f(U)$, we would have $y \in U \cap f(U) = H$, a contradiction. Similarly, $x + y \notin f(U)$. It follows that

$$U + f(U) = U \oplus K(x + y) = f(U) \oplus K(x + y).$$

Now, pick W to be any supplement of $U + f(U)$ in D^\perp so that $D^\perp = (U + f(U)) \oplus W$, and let

$$V = K(x + y) + W.$$

Then, since $x \in U, y \in f(U)$, $W \subseteq D^\perp$, and $U + f(U) \subseteq D^\perp$, we have $V \subseteq D^\perp$. We also have

$$U \oplus V = U \oplus K(x + y) \oplus W = (U + f(U)) \oplus W = D^\perp$$

and

$$f(U) \oplus V = f(U) \oplus K(x + y) \oplus W = (U + f(U)) \oplus W = D^\perp,$$

so as we showed as a consequence of hypothesis (V), f can be extended to an isometry of the hyperplane $D^\perp = U \oplus V$, and D is still the line $\{f(w) - w \mid w \in U \oplus V\}$. \square

The argument in the proof of Case (b) shows that we are reduced to the situation where $U = D^\perp$ is a hyperplane in E and f is an isometry of U . If we pick any $v \notin U$, then $E = U \oplus Kv$, so suppose we can find some $v_1 \in E$ such that

$$\begin{aligned} \varphi(f(u), v_1) &= \varphi(u, v) \quad \text{for all } u \in U \\ \varphi(v_1, v_1) &= \varphi(v, v). \end{aligned}$$

The first condition is condition (*) of Proposition 29.44, and the second condition asserts that the map $\lambda v \mapsto \lambda v_2$ from the line Kv to the line Kv_1 is a metric map. Then, by Proposition 29.44, we can extend f to a metric map g of $U + Kv = E$ such that $g(v) = v_1$.

To find v_1 , let us prove that for every $v \in E$, there is some $v' \in E$ such that

$$\varphi(f(u), v') = \varphi(u, v) \quad \text{for all } u \in U. \tag{\dagger}$$

This is because the linear form $u \mapsto \varphi(f^{-1}(u), v)$ ($u \in U$) is the restriction of a linear form $\psi \in E^*$, and since φ is nondegenerate, there is some (unique) $v' \in E$, such that

$$\psi(x) = \varphi(x, v') \quad \text{for all } x \in E,$$

which implies that

$$\varphi(u, v') = \varphi(f^{-1}(u), v) \quad \text{for all } u \in U,$$

and since f is an automorphism of U , that (\dagger) holds. Furthermore, observe that formula (\dagger) still holds if we add to v' any vector y in D , since $f(U) = U = D^\perp$. Therefore, for any $v_1 = v' + y$ with $y \in D$, if we extend f to a linear map of E by setting $g(v) = v_1$, then by (\dagger) we have

$$\varphi(g(u), g(v)) = \varphi(u, v) \quad \text{for all } u \in U.$$

We still need to pick $y \in D$ so that $v_1 = v' + y$ satisfies $\varphi(v_1, v_1) = \varphi(v, v)$. However, since $v \notin U = D^\perp$, the vector v is not orthogonal to D , and by Lemma 29.28, there is some $y_0 \in D$ such that

$$\varphi(v' + y_0, v' + y_0) = \varphi(v, v).$$

Then, if we let $v_1 = v' + y_0$, by Proposition 29.44, we can extend f to a metric map g of $U + Kv = E$ by setting $g(v) = v_1$. Since φ is nondegenerate, g is an isometry. \square

The first corollary of Witt's theorem is sometimes called the Witt's cancellation theorem.

Theorem 29.46. (*Witt Cancellation Theorem*) *Let (E_1, φ_1) and (E_2, φ_2) be two pairs of finite-dimensional spaces and nondegenerate ϵ -Hermitian forms satisfying condition (T), and assume that (E_1, φ_1) and (E_2, φ_2) are isometric. For any subspace U of E_1 and any subspace V of E_2 , if there is an isometry $f: U \rightarrow V$, then there is an isometry $g: U^\perp \rightarrow V^\perp$.*

Proof. If $f: U \rightarrow V$ is an isometry between U and V , by Witt's theorem (Theorem 29.46), the linear map f extends to an isometry g between E_1 and E_2 . We claim that g maps U^\perp into V^\perp . This is because if $v \in U^\perp$, we have $\varphi_1(u, v) = 0$ for all $u \in U$, so

$$\varphi_2(g(u), g(v)) = \varphi_1(u, v) = 0 \quad \text{for all } u \in U,$$

and since g is a bijection between U and V , we have $g(U) = V$, so we see that $g(v)$ is orthogonal to V for every $v \in U^\perp$; that is, $g(U^\perp) \subseteq V^\perp$. Since g is a metric map and since φ_1 is nondegenerate, the restriction of g to U^\perp is an isometry from U^\perp to V^\perp . \square

A pair (E, φ) where E is finite-dimensional and φ is a nondegenerate ϵ -Hermitian form is often called an ϵ -Hermitian space. When $\epsilon = 1$ and φ is symmetric, we use the term *Euclidean* space or *quadratic* space. When $\epsilon = -1$ and φ is alternating, we use the term *symplectic* space. When $\epsilon = 1$ and the automorphism $\lambda \mapsto \bar{\lambda}$ is not the identity we use the term *Hermitian* space, and when $\epsilon = -1$, we use the term *skew-Hermitian* space.

We also have the following result showing that the group of isometries of an ϵ -Hermitian space is transitive on totally isotropic subspaces of the same dimension.

Theorem 29.47. *Let E be a finite-dimensional vector space and let φ be a nondegenerate ϵ -Hermitian form on E satisfying condition (T). Then for any two totally isotropic subspaces U and V of the same dimension, there is an isometry $f \in \mathbf{Isom}(\varphi)$ such that $f(U) = V$. Furthermore, every linear automorphism of U is induced by an isometry of E .*

Remark: Witt's cancelation theorem can be used to define an equivalence relation on ϵ -Hermitian spaces and to define a group structure on these equivalence classes. This way, we obtain the *Witt group*, but we will not discuss it here.

Witt's Theorem can be sharpened to isometries in $\mathbf{SO}(\varphi)$, but some condition on U is needed.

Theorem 29.48. (*Witt-Sharpened Version*) Let E be a finite-dimensional space equipped with a nondegenerate symmetric bilinear forms φ . For any subspace U of E , every linear injective metric map f from U into E extends to an isometry g of E with a prescribed value ± 1 of $\det(g)$ iff

$$\dim(U) + \dim(\text{rad}(U)) < \dim(E) = n.$$

If

$$\dim(U) + \dim(\text{rad}(U)) = \dim(E) = n,$$

and $\det(f) = -1$, then there is no $g \in \mathbf{SO}(\varphi)$ extending f .

Proof. If g_1 and g_2 are two extensions of f such that $\det(g_1)\det(g_2) = -1$, then $h = g_1^{-1} \circ g_2$ is an isometry such that $\det(h) = -1$, and h leaves every vector of U fixed. Conversely, if h is an isometry such that $\det(h) = -1$, and $h(u) = u$ for all $u \in U$, then for any extension g_1 of f , the map $g_2 = h \circ g_1$ is another extension of f such that $\det(g_2) = -\det(g_1)$. Therefore, we need to show that a map h as above exists.

If $\dim(U) + \dim(\text{rad}(U)) < \dim(E)$, consider the nondegenerate completion \overline{U} of U given by Proposition 29.32. We know that $\dim(\overline{U}) = \dim(U) + \dim(\text{rad}(U)) < n$, and since \overline{U} is nondegenerate, we have

$$E = \overline{U} \overset{\perp}{\oplus} \overline{U}^{\perp},$$

with $\overline{U}^{\perp} \neq (0)$. Pick any isometry τ of \overline{U}^{\perp} such that $\det(\tau) = -1$, and extend it to an isometry h of E whose restriction to \overline{U} is the identity.

If $\dim(U) + \dim(\text{rad}(U)) = \dim(E) = n$, then $U = V \overset{\perp}{\oplus} W$ with $V = \text{rad}(U)$ and since $\dim(\overline{U}) = \dim(U) + \dim(\text{rad}(U)) = n$, we have

$$E = \overline{U} = (V \oplus V') \overset{\perp}{\oplus} W,$$

where $V \oplus V' = \text{Ar}_{2r} = W^{\perp}$ is an Artinian space. Any isometry h of E which is the identity on U and with $\det(h) = -1$ is the identity on W , and thus it must map $W^{\perp} = \text{Ar}_{2r} = V \oplus V'$ into itself, and the restriction h' of h to Ar_{2r} has $\det(h') = -1$. However, h' is the identity on $V = \text{rad}(U)$, a totally isotropic subspace of Ar_{2r} of dimension r , and by Proposition 29.42, we have $\det(h') = +1$, a contradiction. \square

It can be shown that the center of $\mathbf{O}(\varphi)$ is $\{\text{id}, -\text{id}\}$. For further properties of orthogonal groups, see Grove [83], Jacobson [98], Taylor [174], and Artin [6].

Chapter 30

Polynomials, Ideals and PID's

30.1 Multisets

This chapter contains a review of polynomials and their basic properties. First, multisets are defined. Polynomials in one variable are defined next. The notion of a polynomial function in one argument is defined. Polynomials in several variables are defined, and so is the notion of a polynomial function in several arguments. The Euclidean division algorithm is presented, and the main consequences of its existence are derived. Ideals are defined, and the characterization of greatest common divisors of polynomials in one variables (gcd's) in terms of ideals is shown. We also prove the Bezout identity. Next, we consider the factorization of polynomials in one variables into irreducible factors. The unique factorization of polynomials in one variable into irreducible factors is shown. Roots of polynomials and their multiplicity are defined. It is shown that a nonnull polynomial in one variable and of degree m over an integral domain has at most m roots. The chapter ends with a brief treatment of polynomial interpolation: Lagrange, Newton, and Hermite interpolants are introduced.

In this chapter, it is assumed that all rings considered are commutative. Recall that a (commutative) ring A is an *integral domain* (or an *entire ring*) if $1 \neq 0$, and if $ab = 0$, then either $a = 0$ or $b = 0$, for all $a, b \in A$. This second condition is equivalent to saying that if $a \neq 0$ and $b \neq 0$, then $ab \neq 0$. Also, recall that $a \neq 0$ is *not* a zero divisor if $ab \neq 0$ whenever $b \neq 0$. Observe that a field is an integral domain.

Our goal is to define polynomials in one or more indeterminates (or variables) X_1, \dots, X_n , with coefficients in a ring A . This can be done in several ways, and we choose a definition that has the advantage of extending immediately from one to several variables. First, we need to review the notion of a (finite) multiset.

Definition 30.1. Given a set I , a (*finite*) *multiset over I* is any function $M: I \rightarrow \mathbb{N}$ such that $M(i) \neq 0$ for finitely many $i \in I$. The multiset M such that $M(i) = 0$ for all $i \in I$ is the *empty multiset*, and it is denoted by 0. If $M(i) = k \neq 0$, we say that i is a *member of M of multiplicity k* . The *union* $M_1 + M_2$ of two multisets M_1 and M_2 is defined such that $(M_1 + M_2)(i) = M_1(i) + M_2(i)$, for every $i \in I$. If I is finite, say $I = \{1, \dots, n\}$, the multiset

M such that $M(i) = k_i$ for every i , $1 \leq i \leq n$, is denoted by $k_1 \cdot 1 + \cdots + k_n \cdot n$, or more simply, by (k_1, \dots, k_n) , and $\deg(k_1 \cdot 1 + \cdots + k_n \cdot n) = k_1 + \cdots + k_n$ is the *size* or *degree* of M . The set of all multisets over I is denoted by $\mathbb{N}^{(I)}$, and when $I = \{1, \dots, n\}$, by $\mathbb{N}^{(n)}$.

Intuitively, the order of the elements of a multiset is irrelevant, but the multiplicity of each element is relevant, contrary to sets. Every $i \in I$ is identified with the multiset M_i such that $M_i(i) = 1$ and $M_i(j) = 0$ for $j \neq i$. When $I = \{1\}$, the set $\mathbb{N}^{(1)}$ of multisets $k \cdot 1$ can be identified with \mathbb{N} and $\{1\}^*$. We will denote $k \cdot 1$ simply by k .

 However, beware that when $n \geq 2$, the set $\mathbb{N}^{(n)}$ of multisets cannot be identified with the set of strings in $\{1, \dots, n\}^*$, because multiset union is commutative, but concatenation of strings in $\{1, \dots, n\}^*$ is not commutative when $n \geq 2$. This is because in a multiset $k_1 \cdot 1 + \cdots + k_n \cdot n$, the order is irrelevant, whereas in a string, the order is relevant. For example, $2 \cdot 1 + 3 \cdot 2 = 3 \cdot 2 + 2 \cdot 1$, but $11222 \neq 22211$, as strings over $\{1, 2\}$.

Nevertheless, $\mathbb{N}^{(n)}$ and the set \mathbb{N}^n of ordered n -tuples under component-wise addition are isomorphic under the map

$$k_1 \cdot 1 + \cdots + k_n \cdot n \mapsto (k_1, \dots, k_n).$$

Thus, since the notation (k_1, \dots, k_n) is less cumbersome than $k_1 \cdot 1 + \cdots + k_n \cdot n$, it will be preferred. We just have to remember that the order of the k_i is really irrelevant.

 But when I is infinite, beware that $\mathbb{N}^{(I)}$ and the set \mathbb{N}^I of ordered I -tuples are not isomorphic.

We are now ready to define polynomials.

30.2 Polynomials

We begin with polynomials in one variable.

Definition 30.2. Given a ring A , we define the set $\mathcal{P}_A(1)$ of *polynomials over A in one variable* as the set of functions $P: \mathbb{N} \rightarrow A$ such that $P(k) \neq 0$ for finitely many $k \in \mathbb{N}$. The polynomial such that $P(k) = 0$ for all $k \in \mathbb{N}$ is the *null (or zero) polynomial* and it is denoted by 0. We define addition of polynomials, multiplication by a scalar, and multiplication of polynomials, as follows: Given any three polynomials $P, Q, R \in \mathcal{P}_A(1)$, letting $a_k = P(k)$, $b_k = Q(k)$, and $c_k = R(k)$, for every $k \in \mathbb{N}$, we define $R = P + Q$ such that

$$c_k = a_k + b_k,$$

$R = \lambda P$ such that

$$c_k = \lambda a_k,$$

where $\lambda \in A$,

and $R = PQ$ such that

$$c_k = \sum_{i+j=k} a_i b_j.$$

We define the polynomial e_k such that $e_k(k) = 1$ and $e_k(i) = 0$ for $i \neq k$. We also denote e_0 by 1 when $k = 0$. Given a polynomial P , the $a_k = P(k) \in A$ are called the *coefficients* of P . If P is not the null polynomial, there is a greatest $n \geq 0$ such that $a_n \neq 0$ (and thus, $a_k = 0$ for all $k > n$) called the *degree* of P and denoted by $\deg(P)$. Then, P is written uniquely as

$$P = a_0 e_0 + a_1 e_1 + \cdots + a_n e_n.$$

When P is the null polynomial, we let $\deg(P) = -\infty$.

There is an injection of A into $\mathcal{P}_A(1)$ given by the map $a \mapsto a1$ (recall that 1 denotes e_0). There is also an injection of \mathbb{N} into $\mathcal{P}_A(1)$ given by the map $k \mapsto e_k$. Observe that $e_k = e_1^k$ (with $e_1^0 = e_0 = 1$). In order to alleviate the notation, we often denote e_1 by X , and we call X a *variable (or indeterminate)*. Then, $e_k = e_1^k$ is denoted by X^k . Adopting this notation, given a nonnull polynomial P of degree n , if $P(k) = a_k$, P is denoted by

$$P = a_0 + a_1 X + \cdots + a_n X^n,$$

or by

$$P = a_n X^n + a_{n-1} X^{n-1} + \cdots + a_0,$$

if this is more convenient (the order of the terms does not matter anyway). Sometimes, it will also be convenient to write a polynomial as

$$P = a_0 X^n + a_1 X^{n-1} + \cdots + a_n.$$

The set $\mathcal{P}_A(1)$ is also denoted by $A[X]$ and a polynomial P may be denoted by $P(X)$. In denoting polynomials, we will use both upper-case and lower-case letters, usually, P, Q, R, S, p, q, r, s , but also f, g, h , etc., if needed (as long as no ambiguities arise).

Given a nonnull polynomial P of degree n , the nonnull coefficient a_n is called the *leading coefficient* of P . The coefficient a_0 is called the *constant term* of P . A polynomial of the form $a_k X^k$ is called a *monomial*. We say that $a_k X^k$ occurs in P if $a_k \neq 0$. A nonzero polynomial P of degree n is called a *monic polynomial (or unitary polynomial, or monic)* if $a_n = 1$, where a_n is its leading coefficient, and such a polynomial can be written as

$$P = X^n + a_{n-1} X^{n-1} + \cdots + a_0 \quad \text{or} \quad P = X^n + a_1 X^{n-1} + \cdots + a_n.$$

The choice of the variable X to denote e_1 is standard practice, but there is nothing special about X . We could have chosen Y, Z , or any other symbol, as long as no ambiguities arise.

Formally, the definition of $\mathcal{P}_A(1)$ has nothing to do with X . The reason for using X is simply convenience. Indeed, it is more convenient to write a polynomial as $P = a_0 + a_1X + \cdots + a_nX^n$ rather than as $P = a_0e_0 + a_1e_1 + \cdots + a_ne_n$.

We have the following simple but crucial proposition.

Proposition 30.1. *Given two nonnull polynomials $P(X) = a_0 + a_1X + \cdots + a_mX^m$ of degree m and $Q(X) = b_0 + b_1X + \cdots + b_nX^n$ of degree n , if either a_m or b_n is not a zero divisor, then $a_m b_n \neq 0$, and thus, $PQ \neq 0$ and*

$$\deg(PQ) = \deg(P) + \deg(Q).$$

In particular, if A is an integral domain, then $A[X]$ is an integral domain.

Proof. Since the coefficient of X^{m+n} in PQ is $a_m b_n$, and since we assumed that either a_m or a_n is not a zero divisor, we have $a_m b_n \neq 0$, and thus, $PQ \neq 0$ and

$$\deg(PQ) = \deg(P) + \deg(Q).$$

Then, it is obvious that $A[X]$ is an integral domain. \square

It is easily verified that $A[X]$ is a commutative ring, with multiplicative identity $1X^0 = 1$. It is also easily verified that $A[X]$ satisfies all the conditions of Definition 3.1, but $A[X]$ is not a vector space, since A is not necessarily a field.

A structure satisfying the axioms of Definition 3.1 when K is a ring (and not necessarily a field) is called a *module*. Modules fail to have some of the nice properties that vector spaces have, and thus, they are harder to study. For example, there are modules that do not have a basis. We postpone the study of modules until Chapter 35.

However, when the ring A is a field, $A[X]$ is a vector space. But even when A is just a ring, the family of polynomials $(X^k)_{k \in \mathbb{N}}$ is a basis of $A[X]$, since every polynomial $P(X)$ can be written in a unique way as $P(X) = a_0 + a_1X + \cdots + a_nX^n$ (with $P(X) = 0$ when $P(X)$ is the null polynomial). Thus, $A[X]$ is a free module.

Next, we want to define the notion of evaluating a polynomial $P(X)$ at some $\alpha \in A$. For this, we need a proposition.

Proposition 30.2. *Let A, B be two rings and let $h: A \rightarrow B$ be a ring homomorphism. For any $\beta \in B$, there is a unique ring homomorphism $\varphi: A[X] \rightarrow B$ extending h such that $\varphi(X) = \beta$, as in the following diagram (where we denote by $h+\beta$ the map $h+\beta: A \cup \{X\} \rightarrow B$ such that $(h+\beta)(a) = h(a)$ for all $a \in A$ and $(h+\beta)(X) = \beta$):*

$$\begin{array}{ccc} A \cup \{X\} & \xrightarrow{\iota} & A[X] \\ & \searrow h+\beta & \downarrow \varphi \\ & & B \end{array}$$

Proof. Let $\varphi(0) = 0$, and for every nonnull polynomial $P(X) = a_0 + a_1X + \cdots + a_nX^n$, let

$$\varphi(P(X)) = h(a_0) + h(a_1)\beta + \cdots + h(a_n)\beta^n.$$

It is easily verified that φ is the unique homomorphism $\varphi: A[X] \rightarrow B$ extending h such that $\varphi(X) = \beta$. \square

Taking $A = B$ in Proposition 30.2 and $h: A \rightarrow A$ the identity, for every $\beta \in A$, there is a unique homomorphism $\varphi_\beta: A[X] \rightarrow A$ such that $\varphi_\beta(X) = \beta$, and for every polynomial $P(X)$, we write $\varphi_\beta(P(X))$ as $P(\beta)$ and we call $P(\beta)$ the *value of $P(X)$ at $X = \beta$* . Thus, we can define a function $P_A: A \rightarrow A$ such that $P_A(\beta) = P(\beta)$, for all $\beta \in A$. This function is called the *polynomial function induced by P* .

More generally, P_B can be defined for any (commutative) ring B such that $A \subseteq B$. In general, it is possible that $P_A = Q_A$ for distinct polynomials P, Q . We will see shortly conditions for which the map $P \mapsto P_A$ is injective. In particular, this is true for $A = \mathbb{R}$ (in general, any infinite integral domain). We now define polynomials in n variables.

Definition 30.3. Given $n \geq 1$ and a ring A , the set $\mathcal{P}_A(n)$ of *polynomials over A in n variables* is the set of functions $P: \mathbb{N}^{(n)} \rightarrow A$ such that $P(k_1, \dots, k_n) \neq 0$ for finitely many $(k_1, \dots, k_n) \in \mathbb{N}^{(n)}$. The polynomial such that $P(k_1, \dots, k_n) = 0$ for all (k_1, \dots, k_n) is the *null (or zero) polynomial* and it is denoted by 0. We define addition of polynomials, multiplication by a scalar, and multiplication of polynomials, as follows: Given any three polynomials $P, Q, R \in \mathcal{P}_A(n)$, letting $a_{(k_1, \dots, k_n)} = P(k_1, \dots, k_n)$, $b_{(k_1, \dots, k_n)} = Q(k_1, \dots, k_n)$, $c_{(k_1, \dots, k_n)} = R(k_1, \dots, k_n)$, for every $(k_1, \dots, k_n) \in \mathbb{N}^{(n)}$, we define $R = P + Q$ such that

$$c_{(k_1, \dots, k_n)} = a_{(k_1, \dots, k_n)} + b_{(k_1, \dots, k_n)},$$

$R = \lambda P$, where $\lambda \in A$, such that

$$c_{(k_1, \dots, k_n)} = \lambda a_{(k_1, \dots, k_n)},$$

and $R = PQ$, such that

$$c_{(k_1, \dots, k_n)} = \sum_{(i_1, \dots, i_n) + (j_1, \dots, j_n) = (k_1, \dots, k_n)} a_{(i_1, \dots, i_n)} b_{(j_1, \dots, j_n)}.$$

For every $(k_1, \dots, k_n) \in \mathbb{N}^{(n)}$, we let $e_{(k_1, \dots, k_n)}$ be the polynomial such that

$$e_{(k_1, \dots, k_n)}(k_1, \dots, k_n) = 1 \quad \text{and} \quad e_{(k_1, \dots, k_n)}(h_1, \dots, h_n) = 0,$$

for $(h_1, \dots, h_n) \neq (k_1, \dots, k_n)$. We also denote $e_{(0, \dots, 0)}$ by 1. Given a polynomial P , the $a_{(k_1, \dots, k_n)} = P(k_1, \dots, k_n) \in A$, are called the *coefficients of P* . If P is not the null polynomial, there is a greatest $d \geq 0$ such that $a_{(k_1, \dots, k_n)} \neq 0$ for some $(k_1, \dots, k_n) \in \mathbb{N}^{(n)}$, with $d = k_1 + \cdots + k_n$, called the *total degree of P* and denoted by $\deg(P)$. Then, P is written uniquely as

$$P = \sum_{(k_1, \dots, k_n) \in \mathbb{N}^{(n)}} a_{(k_1, \dots, k_n)} e_{(k_1, \dots, k_n)}.$$

When P is the null polynomial, we let $\deg(P) = -\infty$.

There is an injection of A into $\mathcal{P}_A(n)$ given by the map $a \mapsto a1$ (where 1 denotes $e_{(0,\dots,0)}$). There is also an injection of $\mathbb{N}^{(n)}$ into $\mathcal{P}_A(n)$ given by the map $(h_1, \dots, h_n) \mapsto e_{(h_1, \dots, h_n)}$. Note that $e_{(h_1, \dots, h_n)}e_{(k_1, \dots, k_n)} = e_{(h_1+k_1, \dots, h_n+k_n)}$. In order to alleviate the notation, let X_1, \dots, X_n be n distinct variables and denote $e_{(0, \dots, 0, 1, 0, \dots, 0)}$, where 1 occurs in the position i , by X_i (where $1 \leq i \leq n$). With this convention, in view of $e_{(h_1, \dots, h_n)}e_{(k_1, \dots, k_n)} = e_{(h_1+k_1, \dots, h_n+k_n)}$, the polynomial $e_{(k_1, \dots, k_n)}$ is denoted by $X_1^{k_1} \cdots X_n^{k_n}$ (with $e_{(0, \dots, 0)} = X_1^0 \cdots X_n^0 = 1$) and it is called a *primitive monomial*. Then, P is also written as

$$P = \sum_{(k_1, \dots, k_n) \in \mathbb{N}^{(n)}} a_{(k_1, \dots, k_n)} X_1^{k_1} \cdots X_n^{k_n}.$$

We also denote $\mathcal{P}_A(n)$ by $A[X_1, \dots, X_n]$. A polynomial $P \in A[X_1, \dots, X_n]$ is also denoted by $P(X_1, \dots, X_n)$.

As in the case $n = 1$, there is nothing special about the choice of X_1, \dots, X_n as variables (or indeterminates). It is just a convenience. After all, the construction of $\mathcal{P}_A(n)$ has nothing to do with X_1, \dots, X_n .

Given a nonnull polynomial P of degree d , the nonnull coefficients $a_{(k_1, \dots, k_n)} \neq 0$ such that $d = k_1 + \cdots + k_n$ are called the *leading coefficients of P* . A polynomial of the form $a_{(k_1, \dots, k_n)} X_1^{k_1} \cdots X_n^{k_n}$ is called a *monomial*. Note that $\deg(a_{(k_1, \dots, k_n)} X_1^{k_1} \cdots X_n^{k_n}) = k_1 + \cdots + k_n$. Given a polynomial

$$P = \sum_{(k_1, \dots, k_n) \in \mathbb{N}^{(n)}} a_{(k_1, \dots, k_n)} X_1^{k_1} \cdots X_n^{k_n},$$

a monomial $a_{(k_1, \dots, k_n)} X_1^{k_1} \cdots X_n^{k_n}$ occurs in the polynomial P if $a_{(k_1, \dots, k_n)} \neq 0$.

A polynomial

$$P = \sum_{(k_1, \dots, k_n) \in \mathbb{N}^{(n)}} a_{(k_1, \dots, k_n)} X_1^{k_1} \cdots X_n^{k_n}$$

is *homogeneous of degree d* if

$$\deg(X_1^{k_1} \cdots X_n^{k_n}) = d,$$

for every monomial $a_{(k_1, \dots, k_n)} X_1^{k_1} \cdots X_n^{k_n}$ occurring in P . If P is a polynomial of total degree d , it is clear that P can be written uniquely as

$$P = P^{(0)} + P^{(1)} + \cdots + P^{(d)},$$

where $P^{(i)}$ is the sum of all monomials of degree i occurring in P , where $0 \leq i \leq d$.

It is easily verified that $A[X_1, \dots, X_n]$ is a commutative ring, with multiplicative identity $1X_1^0 \cdots X_n^0 = 1$. It is also easily verified that $A[X]$ is a module. When A is a field, $A[X]$ is a vector space.

Even when A is just a ring, the family of polynomials

$$(X_1^{k_1} \cdots X_n^{k_n})_{(k_1, \dots, k_n) \in \mathbb{N}^{(n)}}$$

is a basis of $A[X_1, \dots, X_n]$, since every polynomial $P(X_1, \dots, X_n)$ can be written in a unique way as

$$P(X_1, \dots, X_n) = \sum_{(k_1, \dots, k_n) \in \mathbb{N}^{(n)}} a_{(k_1, \dots, k_n)} X_1^{k_1} \cdots X_n^{k_n}.$$

Thus, $A[X_1, \dots, X_n]$ is a free module.

Remark: The construction of Definition 30.3 can be immediately extended to an arbitrary set I , and not just $I = \{1, \dots, n\}$. It can also be applied to monoids more general than $\mathbb{N}^{(I)}$.

Proposition 30.2 is generalized as follows.

Proposition 30.3. *Let A, B be two rings and let $h: A \rightarrow B$ be a ring homomorphism. For any $\beta = (\beta_1, \dots, \beta_n) \in B^n$, there is a unique ring homomorphism $\varphi: A[X_1, \dots, X_n] \rightarrow B$ extending h such that $\varphi(X_i) = \beta_i$, $1 \leq i \leq n$, as in the following diagram (where we denote by $h + \beta$ the map $h + \beta: A \cup \{X_1, \dots, X_n\} \rightarrow B$ such that $(h + \beta)(a) = h(a)$ for all $a \in A$ and $(h + \beta)(X_i) = \beta_i$, $1 \leq i \leq n$):*

$$\begin{array}{ccc} A \cup \{X_1, \dots, X_n\} & \xrightarrow{\iota} & A[X_1, \dots, X_n] \\ & \searrow^{h+\beta} & \downarrow \varphi \\ & & B \end{array}$$

Proof. Let $\varphi(0) = 0$, and for every nonnull polynomial

$$P(X_1, \dots, X_n) = \sum_{(k_1, \dots, k_n) \in \mathbb{N}^{(n)}} a_{(k_1, \dots, k_n)} X_1^{k_1} \cdots X_n^{k_n},$$

let

$$\varphi(P(X_1, \dots, X_n)) = \sum h(a_{(k_1, \dots, k_n)}) \beta_1^{k_1} \cdots \beta_n^{k_n}.$$

It is easily verified that φ is the unique homomorphism $\varphi: A[X_1, \dots, X_n] \rightarrow B$ extending h such that $\varphi(X_i) = \beta_i$. \square

Taking $A = B$ in Proposition 30.3 and $h: A \rightarrow A$ the identity, for every $\beta_1, \dots, \beta_n \in A$, there is a unique homomorphism $\varphi: A[X_1, \dots, X_n] \rightarrow A$ such that $\varphi(X_i) = \beta_i$, and for every polynomial $P(X_1, \dots, X_n)$, we write $\varphi(P(X_1, \dots, X_n))$ as $P(\beta_1, \dots, \beta_n)$ and we call $P(\beta_1, \dots, \beta_n)$ the *value of $P(X_1, \dots, X_n)$ at $X_1 = \beta_1, \dots, X_n = \beta_n$* . Thus, we can define a function $P_A: A^n \rightarrow A$ such that $P_A(\beta_1, \dots, \beta_n) = P(\beta_1, \dots, \beta_n)$, for all $\beta_1, \dots, \beta_n \in A$. This function is called the *polynomial function induced by P* .

More generally, P_B can be defined for any (commutative) ring B such that $A \subseteq B$. As in the case of a single variable, it is possible that $P_A = Q_A$ for distinct polynomials P, Q . We will see shortly that the map $P \mapsto P_A$ is injective when $A = \mathbb{R}$ (in general, any infinite integral domain).

Given any nonnull polynomial $P(X_1, \dots, X_n) = \sum_{(k_1, \dots, k_n) \in \mathbb{N}^{(n)}} a_{(k_1, \dots, k_n)} X_1^{k_1} \cdots X_n^{k_n}$ in $A[X_1, \dots, X_n]$, where $n \geq 2$, $P(X_1, \dots, X_n)$ can be uniquely written as

$$P(X_1, \dots, X_n) = \sum Q_{k_n}(X_1, \dots, X_{n-1}) X_n^{k_n},$$

where each polynomial $Q_{k_n}(X_1, \dots, X_{n-1})$ is in $A[X_1, \dots, X_{n-1}]$. Even if A is a field, $A[X_1, \dots, X_{n-1}]$ is not a field, which confirms that it is useful (and necessary!) to consider polynomials over rings that are not necessarily fields.

It is not difficult to show that $A[X_1, \dots, X_n]$ and $A[X_1, \dots, X_{n-1}][X_n]$ are isomorphic rings. This way, it is often possible to prove properties of polynomials in several variables X_1, \dots, X_n , by induction on the number n of variables. For example, given two nonnull polynomials $P(X_1, \dots, X_n)$ of total degree p and $Q(X_1, \dots, X_n)$ of total degree q , since we assumed that A is an integral domain, we can prove that

$$\deg(PQ) = \deg(P) + \deg(Q),$$

and that $A[X_1, \dots, X_n]$ is an integral domain.

Next, we will consider the division of polynomials (in one variable).

30.3 Euclidean Division of Polynomials

We know that every natural number $n \geq 2$ can be written uniquely as a product of powers of prime numbers and that prime numbers play a very important role in arithmetic. It would be nice if every polynomial could be expressed (uniquely) as a product of “irreducible” factors. This is indeed the case for polynomials over a field. The fact that there is a division algorithm for the natural numbers is essential for obtaining many of the arithmetical properties of the natural numbers. As we shall see next, there is also a division algorithm for polynomials in $A[X]$, when A is a field.

Proposition 30.4. *Let A be a ring, let $f(X), g(X) \in A[X]$ be two polynomials of degree $m = \deg(f)$ and $n = \deg(g)$ with $f(X) \neq 0$, and assume that the leading coefficient a_m of $f(X)$ is invertible. Then, there exist unique polynomials $q(X)$ and $r(X)$ in $A[X]$ such that*

$$g = f q + r \quad \text{and} \quad \deg(r) < \deg(f) = m.$$

Proof. We first prove the existence of q and r . Let

$$f = a_m X^m + a_{m-1} X^{m-1} + \cdots + a_0,$$

and

$$g = b_n X^n + b_{n-1} X^{n-1} + \cdots + b_0.$$

If $n < m$, then let $q = 0$ and $r = g$. Since $\deg(g) < \deg(f)$ and $r = g$, we have $\deg(r) < \deg(f)$.

If $n \geq m$, we proceed by induction on n . If $n = 0$, then $g = b_0$, $m = 0$, $f = a_0 \neq 0$, and we let $q = a_0^{-1}b_0$ and $r = 0$. Since $\deg(r) = \deg(0) = -\infty$ and $\deg(f) = \deg(a_0) = 0$ because $a_0 \neq 0$, we have $\deg(r) < \deg(f)$.

If $n \geq 1$, since $n \geq m$, note that

$$\begin{aligned} g_1(X) &= g(X) - b_n a_m^{-1} X^{n-m} f(X) \\ &= b_n X^n + b_{n-1} X^{n-1} + \cdots + b_0 - b_n a_m^{-1} X^{n-m} (a_m X^m + a_{m-1} X^{m-1} + \cdots + a_0) \end{aligned}$$

is a polynomial of degree $\deg(g_1) < n$, since the terms $b_n X^n$ and $b_n a_m^{-1} X^{n-m} a_m X^m$ of degree n cancel out. Now, since $\deg(g_1) < n$, by the induction hypothesis, we can find q_1 and r such that

$$g_1 = f q_1 + r \quad \text{and} \quad \deg(r) < \deg(f) = m,$$

and thus,

$$g_1(X) = g(X) - b_n a_m^{-1} X^{n-m} f(X) = f(X) q_1(X) + r(X),$$

from which, letting $q(X) = b_n a_m^{-1} X^{n-m} + q_1(X)$, we get

$$g = f q + r \quad \text{and} \quad \deg(r) < m = \deg(f).$$

We now prove uniqueness. If

$$g = f q_1 + r_1 = f q_2 + r_2,$$

with $\deg(r_1) < \deg(f)$ and $\deg(r_2) < \deg(f)$, we get

$$f(q_1 - q_2) = r_2 - r_1.$$

If $q_2 - q_1 \neq 0$, since the leading coefficient a_m of f is invertible, by Proposition 30.1, we have

$$\deg(r_2 - r_1) = \deg(f(q_1 - q_2)) = \deg(f) + \deg(q_2 - q_1),$$

and so, $\deg(r_2 - r_1) \geq \deg(f)$, which contradicts the fact that $\deg(r_1) < \deg(f)$ and $\deg(r_2) < \deg(f)$. Thus, $q_1 = q_2$, and then also $r_1 = r_2$. \square

It should be noted that the proof of Proposition 30.4 actually provides an algorithm for finding the *quotient* q and the *remainder* r of the division of g by f . This algorithm is called the *Euclidean algorithm, or division algorithm*. Note that the division of g by f is always possible when f is a monic polynomial, since 1 is invertible. Also, when A is a field, $a_m \neq 0$ is always invertible, and thus, the division can always be performed. We say that f divides g when $r = 0$ in the result of the division $g = f q + r$. We now draw some important consequences of the existence of the Euclidean algorithm.

30.4 Ideals, PID's, and Greatest Common Divisors

First, we introduce the fundamental concept of an ideal.

Definition 30.4. Given a ring A , an *ideal of A* is any nonempty subset \mathfrak{I} of A satisfying the following two properties:

- (ID1) If $a, b \in \mathfrak{I}$, then $b - a \in \mathfrak{I}$.
- (ID2) If $a \in \mathfrak{I}$, then $ax \in \mathfrak{I}$ for every $x \in A$.

An ideal \mathfrak{I} is a *principal ideal* if there is some $a \in \mathfrak{I}$, called a *generator*, such that

$$\mathfrak{I} = \{ax \mid x \in A\}.$$

The equality $\mathfrak{I} = \{ax \mid x \in A\}$ is also written as $\mathfrak{I} = aA$ or as $\mathfrak{I} = (a)$. The ideal $\mathfrak{I} = (0) = \{0\}$ is called the *null ideal* (or *zero ideal*).

An ideal \mathfrak{I} is a *maximal ideal* if $\mathfrak{I} \neq A$ and for every ideal $\mathfrak{J} \neq A$, if $\mathfrak{J} \subseteq \mathfrak{I}$, then $\mathfrak{J} = \mathfrak{I}$. An ideal \mathfrak{I} is a *prime ideal* if $\mathfrak{I} \neq A$ and if $ab \in \mathfrak{I}$, then $a \in \mathfrak{I}$ or $b \in \mathfrak{I}$, for all $a, b \in A$. Equivalently, \mathfrak{I} is a prime ideal if $\mathfrak{I} \neq A$ and if $a, b \in A - \mathfrak{I}$, then $ab \in A - \mathfrak{I}$, for all $a, b \in A$. In other words, $A - \mathfrak{I}$ is closed under multiplication and $1 \in A - \mathfrak{I}$.

Note that if \mathfrak{I} is an ideal, then $\mathfrak{I} = A$ iff $1 \in \mathfrak{I}$. Since by definition, an ideal \mathfrak{I} is nonempty, there is some $a \in \mathfrak{I}$, and by (ID1) we get $0 = a - a \in \mathfrak{I}$. Then, for every $a \in \mathfrak{I}$, since $0 \in \mathfrak{I}$, by (ID1) we get $-a \in \mathfrak{I}$. Thus, an ideal is an additive subgroup of A . Because of (ID2), an ideal is also a subring.

Observe that if A is a field, then A only has two ideals, namely, the trivial ideal (0) and A itself. Indeed, if $\mathfrak{I} \neq (0)$, because every nonnull element has an inverse, then $1 \in \mathfrak{I}$, and thus, $\mathfrak{I} = A$.

Definition 30.5. Given a ring A , for any two elements $a, b \in A$ we say that b is a *multiple of a* and that a divides b if $b = ac$ for some $c \in A$; this is usually denoted by $a \mid b$.

Note that the principal ideal (a) is the set of all multiples of a , and that a divides b iff b is a multiple of a iff $b \in (a)$ iff $(b) \subseteq (a)$.

Note that every $a \in A$ divides 0. However, it is customary to say that a is a *zero divisor* iff $ac = 0$ for some $c \neq 0$. With this convention, 0 is a zero divisor unless $A = \{0\}$ (the trivial ring), and A is an integral domain iff 0 is the only zero divisor in A .

Given $a, b \in A$ with $a, b \neq 0$, if $(a) = (b)$ then there exist $c, d \in A$ such that $a = bc$ and $b = ad$. From this, we get $a = adc$ and $b = bcd$, that is, $a(1 - dc) = 0$ and $b(1 - cd) = 0$. If A is an integral domain, we get $dc = 1$ and $cd = 1$, that is, c is invertible with inverse d . Thus, when A is an integral domain, we have $b = ad$, with d invertible. The converse is obvious, if $b = ad$ with d invertible, then $(a) = (b)$.

It is worth recording this fact as the following proposition.

Proposition 30.5. *If A is an integral domain, for any $a, b \in A$ with $a, b \neq 0$, we have $(a) = (b)$ iff there exists some invertible $d \in A$ such that $b = ad$.*

An invertible element $u \in A$ is also called a *unit*.

Given two ideals \mathfrak{I} and \mathfrak{J} , their sum

$$\mathfrak{I} + \mathfrak{J} = \{a + b \mid a \in \mathfrak{I}, b \in \mathfrak{J}\}$$

is clearly an ideal. Given any nonempty subset J of A , the set

$$\{a_1x_1 + \cdots + a_nx_n \mid x_1, \dots, x_n \in A, a_1, \dots, a_n \in J, n \geq 1\}$$

is easily seen to be an ideal, and in fact, it is the smallest ideal containing J . It is usually denoted by (J) .

Ideals play a very important role in the study of rings. They tend to show up everywhere. For example, they arise naturally from homomorphisms.

Proposition 30.6. *Given any ring homomorphism $h: A \rightarrow B$, the kernel $\text{Ker } h = \{a \in A \mid h(a) = 0\}$ of h is an ideal.*

Proof. Given $a, b \in A$, we have $a, b \in \text{Ker } h$ iff $h(a) = h(b) = 0$, and since h is a homomorphism, we get

$$h(b - a) = h(b) - h(a) = 0,$$

and

$$h(ax) = h(a)h(x) = 0$$

for all $x \in A$, which shows that $\text{Ker } h$ is an ideal. \square

There is a sort of converse property. Given a ring A and an ideal $\mathfrak{I} \subseteq A$, we can define the quotient ring A/\mathfrak{I} , and there is a surjective homomorphism $\pi: A \rightarrow A/\mathfrak{I}$ whose kernel is precisely \mathfrak{I} .

Proposition 30.7. *Given any ring A and any ideal $\mathfrak{I} \subseteq A$, the equivalence relation $\equiv_{\mathfrak{I}}$ defined by $a \equiv_{\mathfrak{I}} b$ iff $b - a \in \mathfrak{I}$ is a congruence, which means that if $a_1 \equiv_{\mathfrak{I}} b_1$ and $a_2 \equiv_{\mathfrak{I}} b_2$, then*

$$1. a_1 + a_2 \equiv_{\mathfrak{I}} b_1 + b_2, \text{ and}$$

$$2. a_1a_2 \equiv_{\mathfrak{I}} b_1b_2.$$

Then, the set A/\mathfrak{I} of equivalence classes modulo \mathfrak{I} is a ring under the operations

$$\begin{aligned} [a] + [b] &= [a + b] \\ [a][b] &= [ab]. \end{aligned}$$

The map $\pi: A \rightarrow A/\mathfrak{I}$ such that $\pi(a) = [a]$ is a surjective homomorphism whose kernel is precisely \mathfrak{I} .

Proof. Everything is straightforward. For example, if $a_1 \equiv_{\mathfrak{I}} b_1$ and $a_2 \equiv_{\mathfrak{I}} b_2$, then $b_1 - a_1 \in \mathfrak{I}$ and $b_2 - a_2 \in \mathfrak{I}$. Since \mathfrak{I} is an ideal, we get

$$(b_1 - a_1)b_2 = b_1b_2 - a_1b_2 \in \mathfrak{I}$$

and

$$(b_2 - a_2)a_1 = a_1b_2 - a_1a_2 \in \mathfrak{I}.$$

Since \mathfrak{I} is an ideal, and thus, an additive group, we get

$$b_1b_2 - a_1a_2 \in \mathfrak{I},$$

i.e., $a_1a_2 \equiv_{\mathfrak{I}} b_1b_2$. The equality $\text{Ker } \pi = \mathfrak{I}$ holds because \mathfrak{I} is an ideal. \square

Example 30.1.

1. In the ring \mathbb{Z} , for every $p \in \mathbb{Z}$, the subgroup $p\mathbb{Z}$ is an ideal, and $\mathbb{Z}/p\mathbb{Z}$ is a ring, the ring of residues modulo p . This ring is a field iff p is a prime number.
2. The quotient of the polynomial ring $\mathbb{R}[X]$ by a prime ideal \mathfrak{I} is an integral domain.
3. The quotient of the polynomial ring $\mathbb{R}[X]$ by a maximal ideal \mathfrak{I} is a field. For example, if $\mathfrak{I} = (X^2 + 1)$, the principal ideal generated by $X^2 + 1$ (which is indeed a maximal ideal since $X^2 + 1$ has no real roots), then $\mathbb{R}[X]/(X^2 + 1) \cong \mathbb{C}$.

The following proposition yields a characterization of prime ideals and maximal ideals in terms of quotients.

Proposition 30.8. *Given a ring A , for any ideal $\mathfrak{I} \subseteq A$, the following properties hold.*

- (1) *The ideal \mathfrak{I} is a prime ideal iff A/\mathfrak{I} is an integral domain.*
- (2) *The ideal \mathfrak{I} is a maximal ideal iff A/\mathfrak{I} is a field.*

Proof. (1) Assume that \mathfrak{I} is a prime ideal. Since \mathfrak{I} is prime, $\mathfrak{I} \neq A$, and thus, A/\mathfrak{I} is not the trivial ring (0) . If $[a][b] = 0$, since $[a][b] = [ab]$, we have $ab \in \mathfrak{I}$, and since \mathfrak{I} is prime, then either $a \in \mathfrak{I}$ or $b \in \mathfrak{I}$, so that either $[a] = 0$ or $[b] = 0$. Thus, A/\mathfrak{I} is an integral domain.

Conversely, assume that A/\mathfrak{I} is an integral domain. Since A/\mathfrak{I} is not the trivial ring, $\mathfrak{I} \neq A$. Assume that $ab \in \mathfrak{I}$. Then, we have

$$\pi(ab) = \pi(a)\pi(b) = 0,$$

which implies that either $\pi(a) = 0$ or $\pi(b) = 0$, since A/\mathfrak{I} is an integral domain (where $\pi: A \rightarrow A/\mathfrak{I}$ is the quotient map). Thus, either $a \in \mathfrak{I}$ or $b \in \mathfrak{I}$, and \mathfrak{I} is a prime ideal.

(2) Assume that \mathfrak{J} is a maximal ideal. As in (1), A/\mathfrak{J} is not the trivial ring (0) . Let $[a] \neq 0$ in A/\mathfrak{J} . We need to prove that $[a]$ has a multiplicative inverse. Since $[a] \neq 0$, we have $a \notin \mathfrak{J}$. Let \mathfrak{J}_a be the ideal generated by \mathfrak{J} and a . We have

$$\mathfrak{J} \subseteq \mathfrak{J}_a \quad \text{and} \quad \mathfrak{J} \neq \mathfrak{J}_a,$$

since $a \notin \mathfrak{J}$, and since \mathfrak{J} is maximal, this implies that

$$\mathfrak{J}_a = A.$$

However, we know that

$$\mathfrak{J}_a = \{ax + h \mid x \in A, h \in \mathfrak{J}\},$$

and thus, there is some $x \in A$ so that

$$ax + h = 1,$$

which proves that $[a][x] = [1]$, as desired.

Conversely, assume that A/\mathfrak{J} is a field. Again, since A/\mathfrak{J} is not the trivial ring, $\mathfrak{J} \neq A$. Let \mathfrak{J} be any proper ideal such that $\mathfrak{J} \subseteq \mathfrak{J}$, and assume that $\mathfrak{J} \neq \mathfrak{J}$. Thus, there is some $j \in \mathfrak{J} - \mathfrak{J}$, and since $\text{Ker } \pi = \mathfrak{J}$, we have $\pi(j) \neq 0$. Since A/\mathfrak{J} is a field and π is surjective, there is some $k \in A$ so that $\pi(j)\pi(k) = 1$, which implies that

$$jk - 1 = i$$

for some $i \in \mathfrak{J}$, and since $\mathfrak{J} \subset \mathfrak{J}$ and \mathfrak{J} is an ideal, it follows that $1 = jk - i \in \mathfrak{J}$, showing that $\mathfrak{J} = A$, a contradiction. Therefore, $\mathfrak{J} = \mathfrak{J}$, and \mathfrak{J} is a maximal ideal. \square

As a corollary, we obtain the following useful result. It emphasizes the importance of maximal ideals.

Corollary 30.9. *Given any ring A , every maximal ideal \mathfrak{J} in A is a prime ideal.*

Proof. If \mathfrak{J} is a maximal ideal, then, by Proposition 30.8, the quotient ring A/\mathfrak{J} is a field. However, a field is an integral domain, and by Proposition 30.8 (again), \mathfrak{J} is a prime ideal. \square

Observe that a ring A is an integral domain iff (0) is a prime ideal. This is an example of a prime ideal which is not a maximal ideal, as immediately seen in $A = \mathbb{Z}$, where (p) is a maximal ideal for every prime number p .

 A less obvious example of a prime ideal which is not a maximal ideal is the ideal (X) in the ring of polynomials $\mathbb{Z}[X]$. Indeed, $(X, 2)$ is also a prime ideal, but (X) is properly contained in $(X, 2)$. The ideal (X) is the set of all polynomials of the form $XQ(X)$ for any $Q(X) \in \mathbb{Z}[X]$, in other words the set of all polynomials in $\mathbb{Z}[X]$ with constant term equal to 0, and the ideal $(X, 2)$ is the set of all polynomials of the form

$$XQ_1(X) + 2Q_2(X), \quad Q_1(X), Q_2(X) \in \mathbb{Z}[X],$$

which is just the set of all polynomials in $\mathbb{Z}[X]$ whose constant term is of the form $2c$ for some $c \in \mathbb{Z}$. The ideal (X) is indeed properly contained in the ideal $(X, 2)$. If $P(X)Q(X) \in (X, 2)$, let a be the constant term in $P(X)$ and let b be the constant term in $Q(X)$. Since $P(X)Q(X) \in (X, 2)$, we must have $ab = 2c$ for some $c \in \mathbb{Z}$, and since 2 is prime, either a is divisible by 2 or b is divisible by 2. It follows that either $P(X) \in (X, 2)$ or $Q(X) \in (X, 2)$, which shows that $(X, 2)$ is a prime ideal.

Definition 30.6. An integral domain in which every ideal is a principal ideal is called a *principal ring* or *principal ideal domain*, for short, a *PID*.

The ring \mathbb{Z} is a PID. This is a consequence of the existence of a (Euclidean) division algorithm. As we shall see next, when K is a field, the ring $K[X]$ is also a principal ring.

However, when $n \geq 2$, the ring $K[X_1, \dots, X_n]$ is not principal. For example, in the ring $K[X, Y]$, the ideal (X, Y) generated by X and Y is not principal. First, since (X, Y) is the set of all polynomials of the form $Xq_1 + Yq_2$, where $q_1, q_2 \in K[X, Y]$, except when $Xq_1 + Yq_2 = 0$, we have $\deg(Xq_1 + Yq_2) \geq 1$. Thus, $1 \notin (X, Y)$. Now if there was some $p \in K[X, Y]$ such that $(X, Y) = (p)$, since $1 \notin (X, Y)$, we must have $\deg(p) \geq 1$. But we would also have $X = pq_1$ and $Y = pq_2$, for some $q_1, q_2 \in K[X, Y]$. Since $\deg(X) = \deg(Y) = 1$, this is impossible.

Even though $K[X, Y]$ is not a principal ring, a suitable version of unique factorization in terms of irreducible factors holds. The ring $K[X, Y]$ (and more generally $K[X_1, \dots, X_n]$) is what is called a *unique factorization domain*, for short, UFD, or a *factorial ring*.

From this point until Definition 30.11, we consider polynomials in one variable over a field K .

Remark: Although we already proved part (1) of Proposition 30.10 in a more general situation above, we reprove it in the special case of polynomials. This may offend the purists, but most readers will probably not mind.

Proposition 30.10. *Let K be a field. The following properties hold:*

- (1) *For any two nonzero polynomials $f, g \in K[X]$, $(f) = (g)$ iff there is some $\lambda \neq 0$ in K such that $g = \lambda f$.*
- (2) *For every nonnull ideal \mathfrak{I} in $K[X]$, there is a unique monic polynomial $f \in K[X]$ such that $\mathfrak{I} = (f)$.*

Proof. (1) If $(f) = (g)$, there are some nonzero polynomials $q_1, q_2 \in K[X]$ such that $g = fq_1$ and $f = gq_2$. Thus, we have $f = fq_1q_2$, which implies $f(1 - q_1q_2) = 0$. Since K is a field, by Proposition 30.1, $K[X]$ has no zero divisor, and since we assumed $f \neq 0$, we must have $q_1q_2 = 1$. However, if either q_1 or q_2 is not a constant, by Proposition 30.1 again, $\deg(q_1q_2) = \deg(q_1) + \deg(q_2) \geq 1$, contradicting $q_1q_2 = 1$, since $\deg(1) = 0$. Thus, both $q_1, q_2 \in K - \{0\}$, and (1) holds with $\lambda = q_1$. In the other direction, it is obvious that $g = \lambda f$ implies that $(f) = (g)$.

(2) Since we are assuming that \mathfrak{I} is not the null ideal, there is some polynomial of smallest degree in \mathfrak{I} , and since K is a field, by suitable multiplication by a scalar, we can make sure that this polynomial is monic. Thus, let f be a monic polynomial of smallest degree in \mathfrak{I} . By (ID2), it is clear that $(f) \subseteq \mathfrak{I}$. Now, let $g \in \mathfrak{I}$. Using the Euclidean algorithm, there exist unique $q, r \in K[X]$ such that

$$g = qf + r \quad \text{and} \quad \deg(r) < \deg(f).$$

If $r \neq 0$, there is some $\lambda \neq 0$ in K such that λr is a monic polynomial, and since $\lambda r = \lambda g - \lambda qf$, with $f, g \in \mathfrak{I}$, by (ID1) and (ID2), we have $\lambda r \in \mathfrak{I}$, where $\deg(\lambda r) < \deg(f)$ and λr is a monic polynomial, contradicting the minimality of the degree of f . Thus, $r = 0$, and $g \in (f)$. The uniqueness of the monic polynomial f follows from (1). \square

Proposition 30.10 shows that $K[X]$ is a principal ring when K is a field.

We now investigate the existence of a greatest common divisor (gcd) for two nonzero polynomials. Given any two nonzero polynomials $f, g \in K[X]$, recall that f divides g if $g = fq$ for some $q \in K[X]$.

Definition 30.7. Given any two nonzero polynomials $f, g \in K[X]$, a polynomial $d \in K[X]$ is a *greatest common divisor of f and g* (for short, a *gcd of f and g*) if d divides f and g and whenever $h \in K[X]$ divides f and g , then h divides d . We say that f and g are *relatively prime* if 1 is a gcd of f and g .

Note that f and g are relatively prime iff all of their gcd's are constants (scalars in K), or equivalently, if f, g have no divisor q of degree $\deg(q) \geq 1$.

In particular, note that f and g are relatively prime when f is a nonzero constant polynomial (a scalar $\lambda \neq 0$ in K) and g is any nonzero polynomial.

We can characterize gcd's of polynomials as follows.

Proposition 30.11. Let K be a field and let $f, g \in K[X]$ be any two nonzero polynomials. For every polynomial $d \in K[X]$, the following properties are equivalent:

- (1) The polynomial d is a gcd of f and g .
- (2) The polynomial d divides f and g and there exist $u, v \in K[X]$ such that

$$d = uf + vg.$$

- (3) The ideals $(f), (g)$, and (d) satisfy the equation

$$(d) = (f) + (g).$$

In addition, $d \neq 0$, and d is unique up to multiplication by a nonzero scalar in K .

Proof. Given any two nonzero polynomials $u, v \in K[X]$, observe that u divides v iff $(v) \subseteq (u)$. Now, (2) can be restated as $(f) \subseteq (d)$, $(g) \subseteq (d)$, and $d \in (f) + (g)$, which is equivalent to $(d) = (f) + (g)$, namely (3).

If (2) holds, since $d = uf + vg$, whenever $h \in K[X]$ divides f and g , then h divides d , and d is a gcd of f and g .

Assume that d is a gcd of f and g . Then, since d divides f and d divides g , we have $(f) \subseteq (d)$ and $(g) \subseteq (d)$, and thus $(f) + (g) \subseteq (d)$, and $(f) + (g)$ is nonempty since f and g are nonzero. By Proposition 30.10, there exists a monic polynomial $d_1 \in K[X]$ such that $(d_1) = (f) + (g)$. Then, d_1 divides both f and g , and since d is a gcd of f and g , then d_1 divides d , which shows that $(d) \subseteq (d_1) = (f) + (g)$. Consequently, $(f) + (g) = (d)$, and (3) holds.

Since $(d) = (f) + (g)$ and f and g are nonzero, the last part of the proposition is obvious. \square

As a consequence of Proposition 30.11, two nonzero polynomials $f, g \in K[X]$ are relatively prime iff there exist $u, v \in K[X]$ such that

$$uf + vg = 1.$$

The identity

$$d = uf + vg$$

of part (2) of Proposition 30.11 is often called the *Bezout identity*.

We derive more useful consequences of Proposition 30.11.

Proposition 30.12. *Let K be a field and let $f, g \in K[X]$ be any two nonzero polynomials. For every gcd $d \in K[X]$ of f and g , the following properties hold:*

- (1) *For every nonzero polynomial $q \in K[X]$, the polynomial dq is a gcd of fq and gq .*
- (2) *For every nonzero polynomial $q \in K[X]$, if q divides f and g , then d/q is a gcd of f/q and g/q .*

Proof. (1) By Proposition 30.11 (2), d divides f and g , and there exist $u, v \in K[X]$, such that

$$d = uf + vg.$$

Then, dq divides fq and gq , and

$$dq = ufq + vgq.$$

By Proposition 30.11 (2), dq is a gcd of fq and gq . The proof of (2) is similar. \square

The following proposition is used often.

Proposition 30.13. (*Euclid's proposition*) Let K be a field and let $f, g, h \in K[X]$ be any nonzero polynomials. If f divides gh and f is relatively prime to g , then f divides h .

Proof. From Proposition 30.11, f and g are relatively prime iff there exist some polynomials $u, v \in K[X]$ such that

$$uf + vg = 1.$$

Then, we have

$$ufh + vgh = h,$$

and since f divides gh , it divides both ufh and vgh , and so, f divides h . \square

Proposition 30.14. Let K be a field and let $f, g_1, \dots, g_m \in K[X]$ be some nonzero polynomials. If f and g_i are relatively prime for all i , $1 \leq i \leq m$, then f and $g_1 \cdots g_m$ are relatively prime.

Proof. We proceed by induction on m . The case $m = 1$ is trivial. Let $h = g_2 \cdots g_m$. By the induction hypothesis, f and h are relatively prime. Let d be a gcd of f and g_1h . We claim that d is relatively prime to g_1 . Otherwise, d and g_1 would have some nonconstant gcd d_1 which would divide both f and g_1 , contradicting the fact that f and g_1 are relatively prime. Now, by Proposition 30.13, since d divides g_1h and d and g_1 are relatively prime, d divides $h = g_2 \cdots g_m$. But then, d is a divisor of f and h , and since f and h are relatively prime, d must be a constant, and f and $g_1 \cdots g_m$ are relatively prime. \square

Definition 30.7 is generalized to any finite number of polynomials as follows.

Definition 30.8. Given any nonzero polynomials $f_1, \dots, f_n \in K[X]$, where $n \geq 2$, a polynomial $d \in K[X]$ is a *greatest common divisor* of f_1, \dots, f_n (for short, a *gcd* of f_1, \dots, f_n) if d divides each f_i and whenever $h \in K[X]$ divides each f_i , then h divides d . We say that f_1, \dots, f_n are *relatively prime* if 1 is a gcd of f_1, \dots, f_n .

It is easily shown that Proposition 30.11 can be generalized to any finite number of polynomials, and similarly for its relevant corollaries. The details are left as an exercise.

Proposition 30.15. Let K be a field and let $f_1, \dots, f_n \in K[X]$ be any $n \geq 2$ nonzero polynomials. For every polynomial $d \in K[X]$, the following properties are equivalent:

- (1) The polynomial d is a gcd of f_1, \dots, f_n .
- (2) The polynomial d divides each f_i and there exist $u_1, \dots, u_n \in K[X]$ such that

$$d = u_1f_1 + \cdots + u_nf_n.$$

- (3) The ideals (f_i) , and (d) satisfy the equation

$$(d) = (f_1) + \cdots + (f_n).$$

In addition, $d \neq 0$, and d is unique up to multiplication by a nonzero scalar in K .

As a consequence of Proposition 30.15, some polynomials $f_1, \dots, f_n \in K[X]$ are relatively prime iff there exist $u_1, \dots, u_n \in K[X]$ such that

$$u_1f_1 + \cdots + u_nf_n = 1.$$

The identity

$$u_1f_1 + \cdots + u_nf_n = 1$$

of part (2) of Proposition 30.15 is also called the *Bezout identity*.

We now consider the factorization of polynomials of a single variable into irreducible factors.

30.5 Factorization and Irreducible Factors in $K[X]$

Definition 30.9. Given a field K , a polynomial $p \in K[X]$ is *irreducible or indecomposable or prime* if $\deg(p) \geq 1$ and if p is not divisible by any polynomial $q \in K[X]$ such that $1 \leq \deg(q) < \deg(p)$. Equivalently, p is irreducible if $\deg(p) \geq 1$ and if $p = q_1q_2$, then either $q_1 \in K$ or $q_2 \in K$ (and of course, $q_1 \neq 0$, $q_2 \neq 0$).

Example 30.2. Every polynomial $aX + b$ of degree 1 is irreducible. Over the field \mathbb{R} , the polynomial $X^2 + 1$ is irreducible (why?), but $X^3 + 1$ is not irreducible, since

$$X^3 + 1 = (X + 1)(X^2 - X + 1).$$

The polynomial $X^2 - X + 1$ is irreducible over \mathbb{R} (why?). It would seem that $X^4 + 1$ is irreducible over \mathbb{R} , but in fact,

$$X^4 + 1 = (X^2 - \sqrt{2}X + 1)(X^2 + \sqrt{2}X + 1).$$

However, in view of the above factorization, $X^4 + 1$ is irreducible over \mathbb{Q} .

It can be shown that the irreducible polynomials over \mathbb{R} are the polynomials of degree 1, or the polynomials of degree 2 of the form $aX^2 + bX + c$, for which $b^2 - 4ac < 0$ (i.e., those having no real roots). This is not easy to prove! Over the complex numbers \mathbb{C} , the only irreducible polynomials are those of degree 1. This is a version of a fact often referred to as the “Fundamental theorem of Algebra”, or, as the French sometimes say, as “d’Alembert’s theorem”!

We already observed that for any two nonzero polynomials $f, g \in K[X]$, f divides g iff $(g) \subseteq (f)$. In view of the definition of a maximal ideal given in Definition 30.4, we now prove that a polynomial $p \in K[X]$ is irreducible iff (p) is a maximal ideal in $K[X]$.

Proposition 30.16. A polynomial $p \in K[X]$ is irreducible iff (p) is a maximal ideal in $K[X]$.

Proof. Since $K[X]$ is an integral domain, for all nonzero polynomials $p, q \in K[X]$, $\deg(pq) = \deg(p) + \deg(q)$, and thus, $(p) \neq K[X]$ iff $\deg(p) \geq 1$. Assume that $p \in K[X]$ is irreducible. Since every ideal in $K[X]$ is a principal ideal, every ideal in $K[X]$ is of the form (q) , for some $q \in K[X]$. If $(p) \subseteq (q)$, with $\deg(q) \geq 1$, then q divides p , and since $p \in K[X]$ is irreducible, this implies that $p = \lambda q$ for some $\lambda \neq 0$ in K , and so, $(p) = (q)$. Thus, (p) is a maximal ideal. Conversely, assume that (p) is a maximal ideal. Then, as we showed above, $\deg(p) \geq 1$, and if q divides p , with $\deg(q) \geq 1$, then $(p) \subseteq (q)$, and since (p) is a maximal ideal, this implies that $(p) = (q)$, which means that $p = \lambda q$ for some $\lambda \neq 0$ in K , and so, p is irreducible. \square

Let $p \in K[X]$ be irreducible. Then, for every nonzero polynomial $g \in K[X]$, either p and g are relatively prime, or p divides g . Indeed, if d is any gcd of p and g , if d is a constant, then p and g are relatively prime, and if not, because p is irreducible, we have $d = \lambda p$ for some $\lambda \neq 0$ in K , and thus, p divides g . As a consequence, if $p, q \in K[X]$ are both irreducible, then either p and q are relatively prime, or $p = \lambda q$ for some $\lambda \neq 0$ in K . In particular, if $p, q \in K[X]$ are both irreducible monic polynomials and $p \neq q$, then p and q are relatively prime.

We now prove the (unique) factorization of polynomials into irreducible factors.

Theorem 30.17. *Given any field K , for every nonzero polynomial*

$$f = a_d X^d + a_{d-1} X^{d-1} + \cdots + a_0$$

of degree $d = \deg(f) \geq 1$ in $K[X]$, there exists a unique set $\{\langle p_1, k_1 \rangle, \dots, \langle p_m, k_m \rangle\}$ such that

$$f = a_d p_1^{k_1} \cdots p_m^{k_m},$$

where the $p_i \in K[X]$ are distinct irreducible monic polynomials, the k_i are (not necessarily distinct) integers, and $m \geq 1$, $k_i \geq 1$.

Proof. First, we prove the existence of such a factorization by induction on $d = \deg(f)$. Clearly, it is enough to prove the result for monic polynomials f of degree $d = \deg(f) \geq 1$. If $d = 1$, then $f = X + a_0$, which is an irreducible monic polynomial.

Assume $d \geq 2$, and assume the induction hypothesis for all monic polynomials of degree $< d$. Consider the set S of all monic polynomials g such that $\deg(g) \geq 1$ and g divides f . Since $f \in S$, the set S is nonempty, and thus, S contains some monic polynomial p_1 of minimal degree. Since $\deg(p_1) \geq 1$, the monic polynomial p_1 must be irreducible. Otherwise we would have $p_1 = g_1 g_2$, for some monic polynomials g_1, g_2 such that $\deg(p_1) > \deg(g_1) \geq 1$ and $\deg(p_1) > \deg(g_2) \geq 1$, and since p_1 divide f , then g_1 would divide f , contradicting the minimality of the degree of p_1 . Thus, we have $f = p_1 q$, for some irreducible monic polynomial p_1 , with q also monic. Since $\deg(p_1) \geq 1$, we have $\deg(q) < \deg(f)$, and we can apply the induction hypothesis to q . Thus, we obtain a factorization of the desired form.

We now prove uniqueness. Assume that

$$f = a_d p_1^{k_1} \cdots p_m^{k_m},$$

and

$$f = a_d q_1^{h_1} \cdots q_n^{h_n}.$$

Thus, we have

$$a_d p_1^{k_1} \cdots p_m^{k_m} = a_d q_1^{h_1} \cdots q_n^{h_n}.$$

We prove that $m = n$, $p_i = q_i$ and $h_i = k_i$, for all i , with $1 \leq i \leq n$.

The proof proceeds by induction on $h_1 + \cdots + h_n$.

If $h_1 + \cdots + h_n = 1$, then $n = 1$ and $h_1 = 1$. Then, since $K[X]$ is an integral domain, we have

$$p_1^{k_1} \cdots p_m^{k_m} = q_1,$$

and since q_1 and the p_i are irreducible monic, we must have $m = 1$ and $p_1 = q_1$.

If $h_1 + \cdots + h_n \geq 2$, since $K[X]$ is an integral domain and since $h_1 \geq 1$, we have

$$p_1^{k_1} \cdots p_m^{k_m} = q_1 q,$$

with

$$q = q_1^{h_1-1} \cdots q_n^{h_n},$$

where $(h_1 - 1) + \cdots + h_n \geq 1$ (and $q_1^{h_1-1} = 1$ if $h_1 = 1$). Now, if q_1 is not equal to any of the p_i , by a previous remark, q_1 and p_i are relatively prime, and by Proposition 30.14, q_1 and $p_1^{k_1} \cdots p_m^{k_m}$ are relatively prime. But this contradicts the fact that q_1 divides $p_1^{k_1} \cdots p_m^{k_m}$. Thus, q_1 is equal to one of the p_i . Without loss of generality, we can assume that $q_1 = p_1$. Then, since $K[X]$ is an integral domain, we have

$$p_1^{k_1-1} \cdots p_m^{k_m} = q_1^{h_1-1} \cdots q_n^{h_n},$$

where $p_1^{k_1-1} = 1$ if $k_1 = 1$, and $q_1^{h_1-1} = 1$ if $h_1 = 1$. Now, $(h_1 - 1) + \cdots + h_n < h_1 + \cdots + h_n$, and we can apply the induction hypothesis to conclude that $m = n$, $p_i = q_i$ and $h_i = k_i$, with $1 \leq i \leq n$. \square

The above considerations about unique factorization into irreducible factors can be extended almost without changes to more general rings known as *Euclidean domains*. In such rings, some abstract version of the division theorem is assumed to hold.

Definition 30.10. A *Euclidean domain* (or *Euclidean ring*) is an integral domain A such that there exists a function $\varphi: A \rightarrow \mathbb{N}$ with the following property: For all $a, b \in A$ with $b \neq 0$, there are some $q, r \in A$ such that

$$a = bq + r \quad \text{and} \quad \varphi(r) < \varphi(b).$$

Note that the pair (q, r) is not necessarily unique.

Actually, unique factorization holds in principal ideal domains (PID's), see Theorem 32.12. As shown below, every Euclidean domain is a PID, and thus, unique factorization holds for Euclidean domains.

Proposition 30.18. *Every Euclidean domain A is a PID.*

Proof. Let \mathfrak{I} be a nonnull ideal in A . Then, the set

$$\{\varphi(a) \mid a \in \mathfrak{I}\}$$

is nonempty, and thus, has a smallest element m . Let b be any (nonnull) element of \mathfrak{I} such that $m = \varphi(b)$. We claim that $\mathfrak{I} = (b)$. Given any $a \in \mathfrak{I}$, we can write

$$a = bq + r$$

for some $q, r \in A$, with $\varphi(r) < \varphi(b)$. Since $b \in \mathfrak{I}$ and \mathfrak{I} is an ideal, we also have $bq \in \mathfrak{I}$, and since $a, bq \in \mathfrak{I}$ and \mathfrak{I} is an ideal, then $r \in \mathfrak{I}$ with $\varphi(r) < \varphi(b) = m$, contradicting the minimality of m . Thus, $r = 0$ and $a \in (b)$. But then,

$$\mathfrak{I} \subseteq (b),$$

and since $b \in \mathfrak{I}$, we get

$$\mathfrak{I} = (b),$$

and A is a PID. □

As a corollary of Proposition 30.18, the ring \mathbb{Z} is a Euclidean domain (using the function $\varphi(a) = |a|$) and thus, a PID. If K is a field, the function φ on $K[X]$ defined such that

$$\varphi(f) = \begin{cases} 0 & \text{if } f = 0, \\ \deg(f) + 1 & \text{if } f \neq 0, \end{cases}$$

shows that $K[X]$ is a Euclidean domain.

Example 30.3. A more interesting example of a Euclidean domain is the ring $\mathbb{Z}[i]$ of *Gaussian integers*, i.e., the subring of \mathbb{C} consisting of all complex numbers of the form $a + ib$, where $a, b \in \mathbb{Z}$. Using the function φ defined such that

$$\varphi(a + ib) = a^2 + b^2,$$

we leave it as an interesting exercise to prove that $\mathbb{Z}[i]$ is a Euclidean domain.

Not every PID is a Euclidean ring.

Remark: Given any integer $d \in \mathbb{Z}$ such that $d \neq 0, 1$ and d does not have any square factor greater than one, the *quadratic field* $\mathbb{Q}(\sqrt{d})$ is the field consisting of all complex numbers of the form $a + ib\sqrt{-d}$ if $d < 0$, and of all the real numbers of the form $a + b\sqrt{d}$ if $d > 0$, with $a, b \in \mathbb{Q}$. The subring of $\mathbb{Q}(\sqrt{d})$ consisting of all elements as above for which $a, b \in \mathbb{Z}$ is denoted by $\mathbb{Z}[\sqrt{d}]$. We define the *ring of integers* of the field $\mathbb{Q}(\sqrt{d})$ as the subring of $\mathbb{Q}(\sqrt{d})$ consisting of the following elements:

- (1) If $d \equiv 2 \pmod{4}$ or $d \equiv 3 \pmod{4}$, then all elements of the form $a + ib\sqrt{-d}$ (if $d < 0$) or all elements of the form $a + b\sqrt{d}$ (if $d > 0$), with $a, b \in \mathbb{Z}$;
- (2) If $d \equiv 1 \pmod{4}$, then all elements of the form $(a + ib\sqrt{-d})/2$ (if $d < 0$) or all elements of the form $(a + b\sqrt{d})/2$ (if $d > 0$), with $a, b \in \mathbb{Z}$ and with a, b either both even or both odd.

Observe that when $d \equiv 2 \pmod{4}$ or $d \equiv 3 \pmod{4}$, the ring of integers of $\mathbb{Q}(\sqrt{d})$ is equal to $\mathbb{Z}[\sqrt{d}]$.

It can be shown that the rings of integers of the fields $\mathbb{Q}(\sqrt{-d})$ where $d = 19, 43, 67, 163$ are PID's, but not Euclidean rings. The proof is hard and long. First, it can be shown that these rings are UFD's (refer to Definition 32.2), see Stark [164] (Chapter 8, Theorems 8.21 and 8.22). Then, we use the fact that the ring of integers of the field $\mathbb{Q}(\sqrt{d})$ (with $d \neq 0, 1$ any square-free integers) is a certain kind of integral domain called a Dedekind ring; see Atiyah-MacDonald [8] (Chapter 9, Theorem 9.5) or Samuel [143] (Chapter III, Section 3.4). Finally, we use the fact that if a Dedekind ring is a UFD then it is a PID, which follows from Proposition 32.13.

Actually, the rings of integers of $\mathbb{Q}(\sqrt{d})$ that are Euclidean domains are completely determined but the proof is quite difficult. It turns out that there are twenty one such rings corresponding to the integers: $-11, -7, -3, -2, -1, 2, 3, 5, 6, 7, 11, 13, 17, 19, 21, 29, 33, 37, 41, 57$ and 73 , see Stark [164] (Chapter 8). For more on quadratic fields and their rings of integers, see Stark [164] (Chapter 8) or Niven, Zuckerman and Montgomery [132] (Chapter 9).

It is possible to characterize a larger class of rings (in terms of ideals), *factorial rings (or unique factorization domains)*, for which unique factorization holds (see Section 32.1). We now consider zeros (or roots) of polynomials.

30.6 Roots of Polynomials

We go back to the general case of an arbitrary ring for a little while.

Definition 30.11. Given a ring A and any polynomial $f \in A[X]$, we say that some $\alpha \in A$ is a *zero of f , or a root of f* , if $f(\alpha) = 0$. Similarly, given a polynomial $f \in A[X_1, \dots, X_n]$, we say that $(\alpha_1, \dots, \alpha_n) \in A^n$ is a *zero of f , or a root of f* , if $f(\alpha_1, \dots, \alpha_n) = 0$.

When $f \in A[X]$ is the null polynomial, every $\alpha \in A$ is trivially a zero of f . This case being trivial, we usually assume that we are considering zeros of nonnull polynomials.

Example 30.4. Considering the polynomial $f(X) = X^2 - 1$, both $+1$ and -1 are zeros of $f(X)$. Over the field of reals, the polynomial $g(X) = X^2 + 1$ has no zeros. Over the field \mathbb{C} of complex numbers, $g(X) = X^2 + 1$ has two roots i and $-i$, the square roots of -1 , which are “imaginary numbers.”

We have the following basic proposition showing the relationship between polynomial division and roots.

Proposition 30.19. *Let $f \in A[X]$ be any polynomial and $\alpha \in A$ any element of A . If the result of dividing f by $X - \alpha$ is $f = (X - \alpha)q + r$, then $r = 0$ iff $f(\alpha) = 0$, i.e., α is a root of f iff $r = 0$.*

Proof. We have $f = (X - \alpha)q + r$, with $\deg(r) < 1 = \deg(X - \alpha)$. Thus, r is a constant in K , and since $f(\alpha) = (\alpha - \alpha)q(\alpha) + r$, we get $f(\alpha) = r$, and the proposition is trivial. \square

We now consider the issue of multiplicity of a root.

Proposition 30.20. *Let $f \in A[X]$ be any nonnull polynomial and $h \geq 0$ any integer. The following conditions are equivalent.*

- (1) *f is divisible by $(X - \alpha)^h$ but not by $(X - \alpha)^{h+1}$.*
- (2) *There is some $g \in A[X]$ such that $f = (X - \alpha)^h g$ and $g(\alpha) \neq 0$.*

Proof. Assume (1). Then, we have $f = (X - \alpha)^h g$ for some $g \in A[X]$. If we had $g(\alpha) = 0$, by Proposition 30.19, g would be divisible by $(X - \alpha)$, and then f would be divisible by $(X - \alpha)^{h+1}$, contradicting (1).

Assume (2), that is, $f = (X - \alpha)^h g$ and $g(\alpha) \neq 0$. If f is divisible by $(X - \alpha)^{h+1}$, then we have $f = (X - \alpha)^{h+1} g_1$, for some $g_1 \in A[X]$. Then, we have

$$(X - \alpha)^h g = (X - \alpha)^{h+1} g_1,$$

and thus

$$(X - \alpha)^h (g - (X - \alpha)g_1) = 0,$$

and since the leading coefficient of $(X - \alpha)^h$ is 1 (show this by induction), by Proposition 30.1, $(X - \alpha)^h$ is not a zero divisor, and we get $g - (X - \alpha)g_1 = 0$, i.e., $g = (X - \alpha)g_1$, and so $g(\alpha) = 0$, contrary to the hypothesis. \square

As a consequence of Proposition 30.20, for every nonnull polynomial $f \in A[X]$ and every $\alpha \in A$, there is a unique integer $h \geq 0$ such that f is divisible by $(X - \alpha)^h$ but not by $(X - \alpha)^{h+1}$. Indeed, since f is divisible by $(X - \alpha)^h$, we have $h \leq \deg(f)$. When $h = 0$, α is not a root of f , i.e., $f(\alpha) \neq 0$. The interesting case is when α is a root of f .

Definition 30.12. Given a ring A and any nonnull polynomial $f \in A[X]$, given any $\alpha \in A$, the unique $h \geq 0$ such that f is divisible by $(X - \alpha)^h$ but not by $(X - \alpha)^{h+1}$ is called the *order, or multiplicity, of α* . We have $h = 0$ iff α is not a root of f , and when α is a root of f , if $h = 1$, we call α a *simple root*, if $h = 2$, a *double root*, and generally, a root of multiplicity $h \geq 2$ is called a *multiple root*.

Observe that Proposition 30.20 (2) implies that if $A \subseteq B$, where A and B are rings, for every nonnull polynomial $f \in A[X]$, if $\alpha \in A$ is a root of f , then the multiplicity of α with respect to $f \in A[X]$ and the multiplicity of α with respect to f considered as a polynomial in $B[X]$, is the same.

We now show that if the ring A is an integral domain, the number of roots of a nonzero polynomial is at most its degree.

Proposition 30.21. Let $f, g \in A[X]$ be nonnull polynomials, let $\alpha \in A$, and let $h \geq 0$ and $k \geq 0$ be the multiplicities of α with respect to f and g . The following properties hold.

- (1) If l is the multiplicity of α with respect to $(f + g)$, then $l \geq \min(h, k)$. If $h \neq k$, then $l = \min(h, k)$.
- (2) If m is the multiplicity of α with respect to fg , then $m \geq h + k$. If A is an integral domain, then $m = h + k$.

Proof. (1) We have $f(X) = (X - \alpha)^h f_1(X)$, $g(X) = (X - \alpha)^k g_1(X)$, with $f_1(\alpha) \neq 0$ and $g_1(\alpha) \neq 0$. Clearly, $l \geq \min(h, k)$. If $h \neq k$, assume $h < k$. Then, we have

$$f(X) + g(X) = (X - \alpha)^h f_1(X) + (X - \alpha)^k g_1(X) = (X - \alpha)^h (f_1(X) + (X - \alpha)^{k-h} g_1(X)),$$

and since $(f_1(X) + (X - \alpha)^{k-h} g_1(X))(\alpha) = f_1(\alpha) \neq 0$, we have $l = h = \min(h, k)$.

- (2) We have

$$f(X)g(X) = (X - \alpha)^{h+k} f_1(X)g_1(X),$$

with $f_1(\alpha) \neq 0$ and $g_1(\alpha) \neq 0$. Clearly, $m \geq h + k$. If A is an integral domain, then $f_1(\alpha)g_1(\alpha) \neq 0$, and so $m = h + k$. \square

Proposition 30.22. Let A be an integral domain. Let f be any nonnull polynomial $f \in A[X]$ and let $\alpha_1, \dots, \alpha_m \in A$ be $m \geq 1$ distinct roots of f of respective multiplicities k_1, \dots, k_m . Then, we have

$$f(X) = (X - \alpha_1)^{k_1} \cdots (X - \alpha_m)^{k_m} g(X),$$

where $g \in A[X]$ and $g(\alpha_i) \neq 0$ for all i , $1 \leq i \leq m$.

Proof. We proceed by induction on m . The case $m = 1$ is obvious in view of Definition 30.12 (which itself, is justified by Proposition 30.20). If $m \geq 2$, by the induction hypothesis, we have

$$f(X) = (X - \alpha_1)^{k_1} \cdots (X - \alpha_{m-1})^{k_{m-1}} g_1(X),$$

where $g_1 \in A[X]$ and $g_1(\alpha_i) \neq 0$, for $1 \leq i \leq m - 1$. Since A is an integral domain and $\alpha_i \neq \alpha_j$ for $i \neq j$, since α_m is a root of f , we have

$$0 = (\alpha_m - \alpha_1)^{k_1} \cdots (\alpha_m - \alpha_{m-1})^{k_{m-1}} g_1(\alpha_m),$$

which implies that $g_1(\alpha_m) = 0$. Now, by Proposition 30.21 (2), since α_m is not a root of the polynomial $(X - \alpha_1)^{k_1} \cdots (X - \alpha_{m-1})^{k_{m-1}}$ and since A is an integral domain, α_m must be a root of multiplicity k_m of g_1 , which means that

$$g_1(X) = (X - \alpha_m)^{k_m} g(X),$$

with $g(\alpha_m) \neq 0$. Since $g_1(\alpha_i) \neq 0$ for $1 \leq i \leq m - 1$ and A is an integral domain, we must also have $g(\alpha_i) \neq 0$, for $1 \leq i \leq m - 1$. Thus, we have

$$f(X) = (X - \alpha_1)^{k_1} \cdots (X - \alpha_m)^{k_m} g(X),$$

where $g \in A[X]$, and $g(\alpha_i) \neq 0$ for $1 \leq i \leq m$. □

As a consequence of Proposition 30.22, we get the following important result.

Theorem 30.23. *Let A be an integral domain. For every nonnull polynomial $f \in A[X]$, if the degree of f is $n = \deg(f)$ and k_1, \dots, k_m are the multiplicities of all the distinct roots of f (where $m \geq 0$), then $k_1 + \cdots + k_m \leq n$.*

Proof. Immediate from Proposition 30.22. □

Since fields are integral domains, Theorem 30.23 holds for nonnull polynomials over fields and in particular, for \mathbb{R} and \mathbb{C} . An important consequence of Theorem 30.23 is the following.

Proposition 30.24. *Let A be an integral domain. For any two polynomials $f, g \in A[X]$, if $\deg(f) \leq n$, $\deg(g) \leq n$, and if there are $n + 1$ distinct elements $\alpha_1, \alpha_2, \dots, \alpha_{n+1} \in A$ (with $\alpha_i \neq \alpha_j$ for $i \neq j$) such that $f(\alpha_i) = g(\alpha_i)$ for all i , $1 \leq i \leq n + 1$, then $f = g$.*

Proof. Assume $f \neq g$, then, $(f - g)$ is nonnull, and since $f(\alpha_i) = g(\alpha_i)$ for all i , $1 \leq i \leq n + 1$, the polynomial $(f - g)$ has $n + 1$ distinct roots. Thus, $(f - g)$ has $n + 1$ distinct roots and is of degree at most n , which contradicts Theorem 30.23. □

Proposition 30.24 is often used to show that polynomials coincide. We will use it to show some interpolation formulae due to Lagrange and Hermite. But first, we characterize the multiplicity of a root of a polynomial. For this, we need the notion of derivative familiar in analysis. Actually, we can simply define this notion algebraically.

First, we need to rule out some undesirable behaviors. Given a field K , as we saw in Example 2.8, we can define a homomorphism $\chi: \mathbb{Z} \rightarrow K$ given by

$$\chi(n) = n \cdot 1,$$

where 1 is the multiplicative identity of K . Recall that we define $n \cdot a$ by

$$n \cdot a = \underbrace{a + \cdots + a}_n$$

if $n \geq 0$ (with $0 \cdot a = 0$) and

$$n \cdot a = -(-n) \cdot a$$

if $n < 0$. We say that the field K is of *characteristic zero* if the homomorphism χ is injective. Then, for any $a \in K$ with $a \neq 0$, we have $n \cdot a \neq 0$ for all $n \neq 0$

The fields \mathbb{Q} , \mathbb{R} , and \mathbb{C} are of characteristic zero. In fact, it is easy to see that every field of characteristic zero contains a subfield isomorphic to \mathbb{Q} . Thus, finite fields can't be of characteristic zero.

Remark: If a field is not of characteristic zero, it is not hard to show that its characteristic, that is, the smallest $n \geq 2$ such that $n \cdot 1 = 0$, is a prime number p . The characteristic p of K is the generator of the principal ideal $p\mathbb{Z}$, the kernel of the homomorphism $\chi: \mathbb{Z} \rightarrow K$. Thus, every finite field is of characteristic some prime p . Infinite fields of nonzero characteristic also exist.

Definition 30.13. Let A be a ring. The *derivative f' , or Df , or D^1f , of a polynomial $f \in A[X]$* is defined inductively as follows:

$$\begin{aligned} f' &= 0, \quad \text{if } f = 0, \text{ the null polynomial,} \\ f' &= 0, \quad \text{if } f = a, a \neq 0, a \in A, \\ f' &= na_nX^{n-1} + (n-1)a_{n-1}X^{n-2} + \cdots + 2a_2X + a_1, \\ &\quad \text{if } f = a_nX^n + a_{n-1}X^{n-1} + \cdots + a_0, \text{ with } n = \deg(f) \geq 1. \end{aligned}$$

If $A = K$ is a field of characteristic zero, if $\deg(f) \geq 1$, the leading coefficient na_n of f' is nonzero, and thus, f' is not the null polynomial. Thus, if $A = K$ is a field of characteristic zero, when $n = \deg(f) \geq 1$, we have $\deg(f') = n - 1$.

For rings or for fields of characteristic $p \geq 2$, we could have $f' = 0$, for a polynomial f of degree ≥ 1 .

The following standard properties of derivatives are recalled without proof (prove them as an exercise).

Given any two polynomials, $f, g \in A[X]$, we have

$$\begin{aligned} (f + g)' &= f' + g', \\ (fg)' &= f'g + fg'. \end{aligned}$$

For example, if $f = (X - \alpha)^k g$ and $k \geq 1$, we have

$$f' = k(X - \alpha)^{k-1}g + (X - \alpha)^kg'.$$

We can now give a criterion for the existence of simple roots. The first proposition holds for any ring.

Proposition 30.25. *Let A be any ring. For every nonnull polynomial $f \in A[X]$, $\alpha \in A$ is a simple root of f iff α is a root of f and α is not a root of f' .*

Proof. Since $\alpha \in A$ is a root of f , we have $f = (X - \alpha)g$ for some $g \in A[X]$. Now, α is a simple root of f iff $g(\alpha) \neq 0$. However, we have $f' = g + (X - \alpha)g'$, and so $f'(\alpha) = g(\alpha)$. Thus, α is a simple root of f iff $f'(\alpha) \neq 0$. \square

We can improve the previous proposition as follows.

Proposition 30.26. *Let A be any ring. For every nonnull polynomial $f \in A[X]$, let $\alpha \in A$ be a root of multiplicity $k \geq 1$ of f . Then, α is a root of multiplicity at least $k - 1$ of f' . If A is a field of characteristic zero, then α is a root of multiplicity $k - 1$ of f' .*

Proof. Since $\alpha \in A$ is a root of multiplicity k of f , we have $f = (X - \alpha)^k g$ for some $g \in A[X]$ and $g(\alpha) \neq 0$. Since

$$f' = k(X - \alpha)^{k-1}g + (X - \alpha)^k g' = (X - \alpha)^{k-1}(kg + (X - \alpha)g'),$$

it is clear that the multiplicity of α w.r.t. f' is at least $k - 1$. Now, $(kg + (X - \alpha)g')(\alpha) = kg(\alpha)$, and if A is of characteristic zero, since $g(\alpha) \neq 0$, then $kg(\alpha) \neq 0$. Thus, α is a root of multiplicity $k - 1$ of f' . \square

As a consequence, we obtain the following test for the existence of a root of multiplicity k for a polynomial f :

Given a field K of characteristic zero, for any nonnull polynomial $f \in K[X]$, any $\alpha \in K$ is a root of multiplicity $k \geq 1$ of f iff α is a root of $f, D^1 f, D^2 f, \dots, D^{k-1} f$, but not a root of $D^k f$.

We can now return to polynomial functions and tie up some loose ends. Given a ring A , recall that every polynomial $f \in A[X_1, \dots, X_n]$ induces a function $f_A: A^n \rightarrow A$ defined such that $f_A(\alpha_1, \dots, \alpha_n) = f(\alpha_1, \dots, \alpha_n)$, for every $(\alpha_1, \dots, \alpha_n) \in A^n$. We now give a sufficient condition for the mapping $f \mapsto f_A$ to be injective.

Proposition 30.27. *Let A be an integral domain. For every polynomial $f \in A[X_1, \dots, X_n]$, if A_1, \dots, A_n are n infinite subsets of A such that $f(\alpha_1, \dots, \alpha_n) = 0$ for all $(\alpha_1, \dots, \alpha_n) \in A_1 \times \dots \times A_n$, then $f = 0$, i.e., f is the null polynomial. As a consequence, if A is an infinite integral domain, then the map $f \mapsto f_A$ is injective.*

Proof. We proceed by induction on n . Assume $n = 1$. If $f \in A[X_1]$ is nonnull, let $m = \deg(f)$ be its degree. Since A_1 is infinite and $f(\alpha_1) = 0$ for all $\alpha_1 \in A_1$, then f has an infinite number of roots. But since f is of degree m , this contradicts Theorem 30.23. Thus, $f = 0$.

If $n \geq 2$, we can view $f \in A[X_1, \dots, X_n]$ as a polynomial

$$f = g_m X_n^m + g_{m-1} X_n^{m-1} + \dots + g_0,$$

where the coefficients g_i are polynomials in $A[X_1, \dots, X_{n-1}]$. Now, for every $(\alpha_1, \dots, \alpha_{n-1}) \in A_1 \times \dots \times A_{n-1}$, $f(\alpha_1, \dots, \alpha_{n-1}, X_n)$ determines a polynomial $h(X_n) \in A[X_n]$, and since A_n is infinite and $h(\alpha_n) = f(\alpha_1, \dots, \alpha_{n-1}, \alpha_n) = 0$ for all $\alpha_n \in A_n$, by the induction hypothesis, we have $g_i(\alpha_1, \dots, \alpha_{n-1}) = 0$. Now, since A_1, \dots, A_{n-1} are infinite, using the induction hypothesis again, we get $g_i = 0$, which shows that f is the null polynomial. The second part of the proposition follows immediately from the first, by letting $A_i = A$. \square

When A is an infinite integral domain, in particular an infinite field, since the map $f \mapsto f_A$ is injective, we identify the polynomial f with the polynomial function f_A , and we write f_A simply as f .

The following proposition can be very useful to show polynomial identities.

Proposition 30.28. *Let A be an infinite integral domain and $f, g_1, \dots, g_m \in A[X_1, \dots, X_n]$ be polynomials. If the g_i are nonnull polynomials and if*

$$f(\alpha_1, \dots, \alpha_n) = 0 \text{ whenever } g_i(\alpha_1, \dots, \alpha_n) \neq 0 \text{ for all } i, 1 \leq i \leq m,$$

for every $(\alpha_1, \dots, \alpha_n) \in A^n$, then

$$f = 0,$$

i.e., f is the null polynomial.

Proof. If f is not the null polynomial, since the g_i are nonnull and A is an integral domain, then the product $f g_1 \cdots g_m$ is nonnull. By Proposition 30.27, only the null polynomial maps to the zero function, and thus there must be some $(\alpha_1, \dots, \alpha_n) \in A^n$, such that

$$f(\alpha_1, \dots, \alpha_n) g_1(\alpha_1, \dots, \alpha_n) \cdots g_m(\alpha_1, \dots, \alpha_n) \neq 0,$$

but this contradicts the hypothesis. \square

Proposition 30.28 is often called the *principle of extension of algebraic identities*. Another perhaps more illuminating way of stating this proposition is as follows: For any polynomial $g \in A[X_1, \dots, X_n]$, let

$$V(g) = \{(\alpha_1, \dots, \alpha_n) \in A^n \mid g(\alpha_1, \dots, \alpha_n) = 0\},$$

the set of zeros of g . Note that $V(g_1) \cup \dots \cup V(g_m) = V(g_1 \cdots g_m)$. Then, Proposition 30.28 can be stated as:

If $f(\alpha_1, \dots, \alpha_n) = 0$ for every $(\alpha_1, \dots, \alpha_n) \in A^n - V(g_1 \cdots g_m)$, then $f = 0$.

In other words, if the algebraic identity $f(\alpha_1, \dots, \alpha_n) = 0$ holds on the complement of $V(g_1) \cup \dots \cup V(g_m) = V(g_1 \cdots g_m)$, then $f(\alpha_1, \dots, \alpha_n) = 0$ holds everywhere in A^n . With this second formulation, we understand better the terminology “principle of extension of algebraic identities.”

Remark: Letting $U(g) = A - V(g)$, the identity $V(g_1) \cup \dots \cup V(g_m) = V(g_1 \dots g_m)$ translates to $U(g_1) \cap \dots \cap U(g_m) = U(g_1 \dots g_m)$. This suggests to define a topology on A whose basis of open sets consists of the sets $U(g)$. In this topology (called the Zariski topology), the sets of the form $V(g)$ are closed sets. Also, when $g_1, \dots, g_m \in A[X_1, \dots, X_n]$ and $n \geq 2$, understanding the structure of the closed sets of the form $V(g_1) \cap \dots \cap V(g_m)$ is quite difficult, and it is the object of algebraic geometry (at least, its classical part).

When $f \in A[X_1, \dots, X_n]$ and $n \geq 2$, one should not apply Proposition 30.27 abusively. For example, let

$$f(X, Y) = X^2 + Y^2 - 1,$$

considered as a polynomial in $\mathbb{R}[X, Y]$. Since \mathbb{R} is an infinite field and since

$$f\left(\frac{1-t^2}{1+t^2}, \frac{2t}{1+t^2}\right) = \frac{(1-t^2)^2}{(1+t^2)^2} + \frac{(2t)^2}{(1+t^2)^2} - 1 = 0,$$

for every $t \in \mathbb{R}$, it would be tempting to say that $f = 0$. But what's wrong with the above reasoning is that there are no two infinite subsets R_1, R_2 of \mathbb{R} such that $f(\alpha_1, \alpha_2) = 0$ for all $(\alpha_1, \alpha_2) \in \mathbb{R}^2$. For every $\alpha_1 \in \mathbb{R}$, there are at most two $\alpha_2 \in \mathbb{R}$ such that $f(\alpha_1, \alpha_2) = 0$. What the example shows though, is that a nonnull polynomial $f \in A[X_1, \dots, X_n]$ where $n \geq 2$ can have an infinite number of zeros. This is in contrast with nonnull polynomials in one variables over an infinite field (which have a number of roots bounded by their degree).

We now look at polynomial interpolation.

30.7 Polynomial Interpolation (Lagrange, Newton, Hermite)

Let K be a field. First, we consider the following interpolation problem: Given a sequence $(\alpha_1, \dots, \alpha_{m+1})$ of pairwise distinct scalars in K and any sequence $(\beta_1, \dots, \beta_{m+1})$ of scalars in K , where the β_j are not necessarily distinct, find a polynomial $P(X)$ of degree $\leq m$ such that

$$P(\alpha_1) = \beta_1, \dots, P(\alpha_{m+1}) = \beta_{m+1}.$$

First, observe that if such a polynomial exists, then it is unique. Indeed, this is a consequence of Proposition 30.24. Thus, we just have to find any polynomial of degree $\leq m$. Consider the following so-called *Lagrange polynomials*:

$$L_i(X) = \frac{(X - \alpha_1) \cdots (X - \alpha_{i-1})(X - \alpha_{i+1}) \cdots (X - \alpha_{m+1})}{(\alpha_i - \alpha_1) \cdots (\alpha_i - \alpha_{i-1})(\alpha_i - \alpha_{i+1}) \cdots (\alpha_i - \alpha_{m+1})}.$$

Note that $L(\alpha_i) = 1$ and that $L(\alpha_j) = 0$, for all $j \neq i$. But then,

$$P(X) = \beta_1 L_1 + \cdots + \beta_{m+1} L_{m+1}$$

is the unique desired polynomial, since clearly, $P(\alpha_i) = \beta_i$. Such a polynomial is called a *Lagrange interpolant*. Also note that the polynomials (L_1, \dots, L_{m+1}) form a basis of the vector space of all polynomials of degree $\leq m$. Indeed, if we had

$$\lambda_1 L_1(X) + \dots + \lambda_{m+1} L_{m+1}(X) = 0,$$

setting X to α_i , we would get $\lambda_i = 0$. Thus, the L_i are linearly independent, and by the previous argument, they are a set of generators. We we call (L_1, \dots, L_{m+1}) the *Lagrange basis* (of order $m + 1$).

It is known from numerical analysis that from a computational point of view, the Lagrange basis is not very good. Newton proposed another solution, the method of divided differences.

Consider the polynomial $P(X)$ of degree $\leq m$, called the *Newton interpolant*,

$$P(X) = \lambda_0 + \lambda_1(X - \alpha_1) + \lambda_2(X - \alpha_1)(X - \alpha_2) + \dots + \lambda_m(X - \alpha_1)(X - \alpha_2) \cdots (X - \alpha_m).$$

Then, the λ_i can be determined by successively setting X to, $\alpha_1, \alpha_2, \dots, \alpha_{m+1}$. More precisely, we define inductively the polynomials $Q(X)$ and $Q(\alpha_1, \dots, \alpha_i, X)$, for $1 \leq i \leq m$, as follows:

$$\begin{aligned} Q(X) &= P(X) \\ Q_1(\alpha_1, X) &= \frac{Q(X) - Q(\alpha_1)}{X - \alpha_1} \\ Q(\alpha_1, \alpha_2, X) &= \frac{Q(\alpha_1, X) - Q(\alpha_1, \alpha_2)}{X - \alpha_2} \\ &\quad \dots \\ Q(\alpha_1, \dots, \alpha_i, X) &= \frac{Q(\alpha_1, \dots, \alpha_{i-1}, X) - Q(\alpha_1, \dots, \alpha_{i-1}, \alpha_i)}{X - \alpha_i}, \\ &\quad \dots \\ Q(\alpha_1, \dots, \alpha_m, X) &= \frac{Q(\alpha_1, \dots, \alpha_{m-1}, X) - Q(\alpha_1, \dots, \alpha_{m-1}, \alpha_m)}{X - \alpha_m}. \end{aligned}$$

By induction on i , $1 \leq i \leq m - 1$, it is easily verified that

$$\begin{aligned} Q(X) &= P(X), \\ Q(\alpha_1, \dots, \alpha_i, X) &= \lambda_i + \lambda_{i+1}(X - \alpha_{i+1}) + \dots + \lambda_m(X - \alpha_{i+1}) \cdots (X - \alpha_m), \\ Q(\alpha_1, \dots, \alpha_m, X) &= \lambda_m. \end{aligned}$$

From the above expressions, it is clear that

$$\begin{aligned} \lambda_0 &= Q(\alpha_1), \\ \lambda_i &= Q(\alpha_1, \dots, \alpha_i, \alpha_{i+1}), \\ \lambda_m &= Q(\alpha_1, \dots, \alpha_m, \alpha_{m+1}). \end{aligned}$$

The expression $Q(\alpha_1, \alpha_2, \dots, \alpha_{i+1})$ is called the *i-th difference quotient*. Then, we can compute the λ_i in terms of $\beta_1 = P(\alpha_1), \dots, \beta_{m+1} = P(\alpha_{m+1})$, using the inductive formulae for the $Q(\alpha_1, \dots, \alpha_i, X)$ given above, initializing the $Q(\alpha_i)$ such that $Q(\alpha_i) = \beta_i$.

The above method is called the method of *divided differences* and it is due to Newton.

An astute observation may be used to optimize the computation. Observe that if $P_i(X)$ is the polynomial of degree $\leq i$ taking the values $\beta_1, \dots, \beta_{i+1}$ at the points $\alpha_1, \dots, \alpha_{i+1}$, then the coefficient of X^i in $P_i(X)$ is $Q(\alpha_1, \alpha_2, \dots, \alpha_{i+1})$, which is the value of λ_i in the Newton interpolant

$$P_i(X) = \lambda_0 + \lambda_1(X - \alpha_1) + \lambda_2(X - \alpha_1)(X - \alpha_2) + \dots + \lambda_i(X - \alpha_1)(X - \alpha_2) \cdots (X - \alpha_i).$$

As a consequence, $Q(\alpha_1, \alpha_2, \dots, \alpha_{i+1})$ does not depend on the specific ordering of the α_j and there are better ways of computing it. For example, $Q(\alpha_1, \alpha_2, \dots, \alpha_{i+1})$ can be computed using

$$Q(\alpha_1, \dots, \alpha_{i+1}) = \frac{Q(\alpha_2, \dots, \alpha_{i+1}) - Q(\alpha_1, \dots, \alpha_i)}{\alpha_{i+1} - \alpha_1}.$$

Then, the computation can be arranged into a triangular array reminiscent of Pascal's triangle, as follows:

Initially, $Q(\alpha_j) = \beta_j$, $1 \leq j \leq m+1$, and

$$\begin{array}{ccccccc} Q(\alpha_1) & & & & & & \\ & Q(\alpha_1, \alpha_2) & & & & & \\ Q(\alpha_2) & & Q(\alpha_1, \alpha_2, \alpha_3) & & & & \\ & Q(\alpha_2, \alpha_3) & & \dots & & & \\ Q(\alpha_3) & & Q(\alpha_2, \alpha_3, \alpha_4) & & & & \\ & Q(\alpha_3, \alpha_4) & & \dots & & & \\ Q(\alpha_4) & & \dots & & & & \\ & & \dots & & & & \end{array}$$

In this computation, each successive column is obtained by forming the difference quotients of the preceding column according to the formula

$$Q(\alpha_k, \dots, \alpha_{i+k}) = \frac{Q(\alpha_{k+1}, \dots, \alpha_{i+k}) - Q(\alpha_k, \dots, \alpha_{i+k-1})}{\alpha_{i+k} - \alpha_k}.$$

The λ_i are the elements of the descending diagonal.

Observe that if we performed the above computation starting with a polynomial $Q(X)$ of degree m , we could extend it by considering new given points $\alpha_{m+2}, \alpha_{m+3}$, etc. Then, from what we saw above, the $(m+1)$ th column consists of λ_m in the expression of $Q(X)$ as a Newton interpolant and the $(m+2)$ th column consists of zeros. Such divided differences are used in numerical analysis.

Newton's method can be used to compute the value $P(\alpha)$ at some α of the interpolant $P(X)$ taking the values $\beta_1, \dots, \beta_{m+1}$ for the (distinct) arguments $\alpha_1, \dots, \alpha_{m+1}$. We also mention that inductive methods for computing $P(\alpha)$ without first computing the coefficients of the Newton interpolant exist, for example, Aitken's method. For this method, the reader is referred to Farin [58].

It has been observed that Lagrange interpolants oscillate quite badly as their degree increases, and thus, this makes them undesirable as a stable method for interpolation. A standard example due to Runge, is the function

$$f(x) = \frac{1}{1+x^2},$$

in the interval $[-5, +5]$. Assuming a uniform distribution of points on the curve in the interval $[-5, +5]$, as the degree of the Lagrange interpolant increases, the interpolant shows wilder and wilder oscillations around the points $x = -5$ and $x = +5$. This phenomenon becomes quite noticeable beginning for degree 14, and gets worse and worse. For degree 22, things are quite bad! Equivalently, one may consider the function

$$f(x) = \frac{1}{1+25x^2},$$

in the interval $[-1, +1]$.

We now consider a more general interpolation problem which will lead to the Hermite polynomials.

We consider the following interpolation problem:

Given a sequence $(\alpha_1, \dots, \alpha_{m+1})$ of pairwise distinct scalars in K , integers n_1, \dots, n_{m+1} where $n_j \geq 0$, and $m+1$ sequences $(\beta_j^0, \dots, \beta_j^{n_j})$ of scalars in K , letting

$$n = n_1 + \dots + n_{m+1} + m,$$

find a polynomial P of degree $\leq n$, such that

$$\begin{aligned} P(\alpha_1) &= \beta_1^0, & \dots & & P(\alpha_{m+1}) &= \beta_{m+1}^0, \\ D^1 P(\alpha_1) &= \beta_1^1, & \dots & & D^1 P(\alpha_{m+1}) &= \beta_{m+1}^1, \\ &&&\dots&& \\ D^i P(\alpha_1) &= \beta_1^i, & \dots & & D^i P(\alpha_{m+1}) &= \beta_{m+1}^i, \\ &&&\dots&& \\ D^{n_1} P(\alpha_1) &= \beta_1^{n_1}, & \dots & & D^{n_{m+1}} P(\alpha_{m+1}) &= \beta_{m+1}^{n_{m+1}}. \end{aligned}$$

Note that the above equations constitute $n+1$ constraints, and thus, we can expect that there is a unique polynomial of degree $\leq n$ satisfying the above problem. This is indeed the case and such a polynomial is called a *Hermite polynomial*. We call the above problem the *Hermite interpolation problem*.

Proposition 30.29. *The Hermite interpolation problem has a unique solution of degree $\leq n$, where $n = n_1 + \dots + n_{m+1} + m$.*

Proof. First, we prove that the Hermite interpolation problem has at most one solution. Assume that P and Q are two distinct solutions of degree $\leq n$. Then, by Proposition 30.26 and the criterion following it, $P - Q$ has among its roots α_1 of multiplicity at least $n_1 + 1, \dots, \alpha_{m+1}$ of multiplicity at least $n_{m+1} + 1$. However, by Theorem 30.23, we should have

$$n_1 + 1 + \dots + n_{m+1} + 1 = n_1 + \dots + n_{m+1} + m + 1 \leq n,$$

which is a contradiction, since $n = n_1 + \dots + n_{m+1} + m$. Thus, $P = Q$. We are left with proving the existence of a Hermite interpolant. A quick way to do so is to use Proposition 7.12, which tells us that given a square matrix A over a field K , the following properties hold:

For every column vector B , there is a unique column vector X such that $AX = B$ iff the only solution to $AX = 0$ is the trivial vector $X = 0$ iff $D(A) \neq 0$.

If we let $P = y_0 + y_1X + \dots + y_nX^n$, the Hermite interpolation problem yields a linear system of equations in the unknowns (y_0, \dots, y_n) with some associated $(n+1) \times (n+1)$ matrix A . Now, the system $AY = 0$ has a solution iff P has among its roots α_1 of multiplicity at least $n_1 + 1, \dots, \alpha_{m+1}$ of multiplicity at least $n_{m+1} + 1$. By the previous argument, since P has degree $\leq n$, we must have $P = 0$, that is, $Y = 0$. This concludes the proof. \square

Proposition 30.29 shows the existence of unique polynomials $H_j^i(X)$ of degree $\leq n$ such that $D^i H_j^i(\alpha_j) = 1$ and $D^k H_j^i(\alpha_l) = 0$, for $k \neq i$ or $l \neq j$, $1 \leq j, l \leq m+1$, $0 \leq i, k \leq n_j$. The polynomials H_j^i are called *Hermite basis polynomials*.

One problem with Proposition 30.29 is that it does not give an explicit way of computing the Hermite basis polynomials. We first show that this can be done explicitly in the special cases $n_1 = \dots = n_{m+1} = 1$, and $n_1 = \dots = n_{m+1} = 2$, and then suggest a method using a generalized Newton interpolant.

Assume that $n_1 = \dots = n_{m+1} = 1$. We try $H_j^0 = (a(X - \alpha_j) + b)L_j^2$, and $H_j^1 = (c(X - \alpha_j) + d)L_j^2$, where L_j is the Lagrange interpolant determined earlier. Since

$$DH_j^0 = aL_j^2 + 2(a(X - \alpha_j) + b)L_j DL_j,$$

requiring that $H_j^0(\alpha_j) = 1$, $H_j^0(\alpha_k) = 0$, $DH_j^0(\alpha_j) = 0$, and $DH_j^0(\alpha_k) = 0$, for $k \neq j$, implies $b = 1$ and $a = -2DL_j(\alpha_j)$. Similarly, from the requirements $H_j^1(\alpha_j) = 0$, $H_j^1(\alpha_k) = 0$, $DH_j^1(\alpha_j) = 1$, and $DH_j^1(\alpha_k) = 0$, $k \neq j$, we get $c = 1$ and $d = 0$.

Thus, we have the Hermite polynomials

$$H_j^0 = (1 - 2DL_j(\alpha_j)(X - \alpha_j))L_j^2, \quad H_j^1 = (X - \alpha_j)L_j^2.$$

In the special case where $m = 1$, $\alpha_1 = 0$, and $\alpha_2 = 1$, we leave as an exercise to show that the Hermite polynomials are

$$\begin{aligned} H_0^0 &= 2X^3 - 3X^2 + 1, \\ H_1^0 &= -2X^3 + 3X^2, \\ H_0^1 &= X^3 - 2X^2 + X, \\ H_1^1 &= X^3 - X^2. \end{aligned}$$

As a consequence, the polynomial P of degree 3 such that $P(0) = x_0$, $P(1) = x_1$, $P'(0) = m_0$, and $P'(1) = m_1$, can be written as

$$P(X) = x_0(2X^3 - 3X^2 + 1) + m_0(X^3 - 2X^2 + X) + m_1(X^3 - X^2) + x_1(-2X^3 + 3X^2).$$

If we want the polynomial P of degree 3 such that $P(a) = x_0$, $P(b) = x_1$, $P'(a) = m_0$, and $P'(b) = m_1$, where $b \neq a$, then we have

$$P(X) = x_0(2t^3 - 3t^2 + 1) + (b-a)m_0(t^3 - 2t^2 + t) + (b-a)m_1(t^3 - t^2) + x_1(-2t^3 + 3t^2),$$

where

$$t = \frac{X - a}{b - a}.$$

Observe the presence of the extra factor $(b - a)$ in front of m_0 and m_1 , the formula would be false otherwise!

We now consider the case where $n_1 = \dots = n_{m+1} = 2$. Let us try

$$H_j^i(X) = (a^i(X - \alpha_j)^2 + b^i(X - \alpha_j) + c^i)L_j^3,$$

where $0 \leq i \leq 2$. Sparing the readers some (tedious) computations, we find:

$$\begin{aligned} H_j^0(X) &= \left((6(DL_j(\alpha_j))^2 - \frac{3}{2}D^2L_j(\alpha_j))(X - \alpha_j)^2 - 3DL_j(\alpha_j)(X - \alpha_j) + 1 \right) L_j^3(X), \\ H_j^1(X) &= \left(9(DL_j(\alpha_j))^2(X - \alpha_j)^2 - 3DL_j(\alpha_j)(X - \alpha_j) \right) L_j^3(X), \\ H_j^2(X) &= \frac{1}{2}(X - \alpha_j)^2 L_j^3(X). \end{aligned}$$

Going back to the general problem, it seems to us that a kind of Newton interpolant will be more manageable. Let

$$\begin{aligned} P_0^0(X) &= 1, \\ P_j^0(X) &= (X - \alpha_1)^{n_1+1} \cdots (X - \alpha_j)^{n_j+1}, \quad 1 \leq j \leq m \\ P_0^i(X) &= (X - \alpha_1)^i(X - \alpha_2)^{n_2+1} \cdots (X - \alpha_{m+1})^{n_{m+1}+1}, \quad 1 \leq i \leq n_1, \\ P_j^i(X) &= (X - \alpha_1)^{n_1+1} \cdots (X - \alpha_j)^{n_j+1} (X - \alpha_{j+1})^i (X - \alpha_{j+2})^{n_{j+2}+1} \cdots (X - \alpha_{m+1})^{n_{m+1}+1}, \\ &\quad 1 \leq j \leq m-1, \quad 1 \leq i \leq n_{j+1}, \\ P_m^i(X) &= (X - \alpha_1)^{n_1+1} \cdots (X - \alpha_m)^{n_m+1} (X - \alpha_{m+1})^i, \quad 1 \leq i \leq n_{m+1}, \end{aligned}$$

and let

$$P(X) = \sum_{\substack{j=0, i=0 \\ j=m, i=n_{j+1}}}^{\substack{j=m, i=n_{j+1} \\ j=0, i=0}} \lambda_j^i P_j^i(X).$$

We can think of $P(X)$ as a generalized Newton interpolant. We can compute the derivatives $D^k P_j^i$, for $1 \leq k \leq n_{j+1}$, and if we look for the Hermite basis polynomials $H_j^i(X)$ such that $D^i H_j^i(\alpha_j) = 1$ and $D^k H_j^i(\alpha_l) = 0$, for $k \neq i$ or $l \neq j$, $1 \leq j, l \leq m + 1$, $0 \leq i, k \leq n_j$, we find that we have to solve triangular systems of linear equations. Thus, as in the simple case $n_1 = \dots = n_{m+1} = 0$, we can solve successively for the λ_j^i . Obviously, the computations are quite formidable and we leave such considerations for further study.

Chapter 31

Annihilating Polynomials and the Primary Decomposition

In this chapter all vector spaces are defined over an arbitrary field K .

In Section 7.7 we explained that if $f: E \rightarrow E$ is a linear map on a K -vector space E , then for any polynomial $p(X) = a_0X^d + a_1X^{d-1} + \cdots + a_d$ with coefficients in the field K , we can define the *linear map* $p(f): E \rightarrow E$ by

$$p(f) = a_0f^d + a_1f^{d-1} + \cdots + a_d\text{id},$$

where $f^k = f \circ \cdots \circ f$, the k -fold composition of f with itself. Note that

$$p(f)(u) = a_0f^d(u) + a_1f^{d-1}(u) + \cdots + a_d u,$$

for every vector $u \in E$. Then we showed that if E is finite-dimensional and if $\chi_f(X) = \det(XI - f)$ is the characteristic polynomial of f , by the Cayley–Hamilton theorem, we have

$$\chi_f(f) = 0.$$

This fact suggests looking at the set of all polynomials $p(X)$ such that

$$p(f) = 0.$$

Such polynomials are called *annihilating polynomials* of f , the set of all these polynomials, denoted $\text{Ann}(f)$, is called the *annihilator* of f , and the Cayley-Hamilton theorem shows that it is nontrivial since it contains a polynomial of positive degree. It turns out that $\text{Ann}(f)$ contains a polynomial m_f of smallest degree that generates $\text{Ann}(f)$, and this polynomial divides the characteristic polynomial. Furthermore, the polynomial m_f encapsulates a lot of information about f , in particular whether f can be diagonalized. One of the main reasons for this is that a scalar $\lambda \in K$ is a zero of the minimal polynomial m_f if and only if λ is an eigenvalue of f .

The first main result is Theorem 31.6 which states that if $f: E \rightarrow E$ is a linear map on a finite-dimensional space E , then f is diagonalizable iff its minimal polynomial m is of the form

$$m = (X - \lambda_1) \cdots (X - \lambda_k),$$

where $\lambda_1, \dots, \lambda_k$ are distinct elements of K .

One of the technical tools used to prove this result is the notion of *f -conductor*; see Definition 31.2. As a corollary of Theorem 31.6 we obtain results about finite commuting families of diagonalizable or triangulable linear maps.

If $f: E \rightarrow E$ is a linear map and $\lambda \in K$ is an eigenvalue of f , recall that the eigenspace E_λ associated with λ is the kernel of the linear map $\lambda \text{id} - f$. If all the eigenvalues $\lambda_1, \dots, \lambda_k$ of f are in K and if f is diagonalizable, then

$$E = E_{\lambda_1} \oplus \cdots \oplus E_{\lambda_k},$$

but in general there are not enough eigenvectors to span E . A remedy is to generalize the notion of eigenvector and look for (nonzero) vectors u (called generalized eigenvectors) such that

$$(\lambda \text{id} - f)^r(u) = 0, \quad \text{for some } r \geq 1.$$

Then, it turns out that if the minimal polynomial of f is of the form

$$m = (X - \lambda_1)^{r_1} \cdots (X - \lambda_k)^{r_k},$$

then $r = r_i$ does the job for λ_i ; that is, if we let

$$W_i = \text{Ker} (\lambda_i \text{id} - f)^{r_i},$$

then

$$E = W_1 \oplus \cdots \oplus W_k.$$

The above facts are parts of the *primary decomposition theorem* (Theorem 31.11). It is a special case of a more general result involving the factorization of the minimal polynomial m into its irreducible monic factors; see Theorem 31.10.

Theorem 31.11 implies that every linear map f that has all its eigenvalues in K can be written as $f = D + N$, where D is diagonalizable and N is nilpotent (which means that $N^r = 0$ for some positive integer r). Furthermore D and N commute and are unique. This is the *Jordan decomposition*, Theorem 31.12.

The Jordan decomposition suggests taking a closer look at nilpotent maps. We prove that for any nilpotent linear map $f: E \rightarrow E$ on a finite-dimensional vector space E of dimension n over a field K , there is a basis of E such that the matrix N of f is of the form

$$N = \begin{pmatrix} 0 & \nu_1 & 0 & \cdots & 0 & 0 \\ 0 & 0 & \nu_2 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 0 & \nu_n \\ 0 & 0 & 0 & \cdots & 0 & 0 \end{pmatrix},$$

where $\nu_i = 1$ or $\nu_i = 0$; see Theorem 31.16. As a corollary we obtain the *Jordan form*; which involves matrices of the form

$$J_r(\lambda) = \begin{pmatrix} \lambda & 1 & 0 & \cdots & 0 \\ 0 & \lambda & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & 0 & \ddots & 1 \\ 0 & 0 & 0 & \cdots & \lambda \end{pmatrix},$$

called *Jordan blocks*; see Theorem 31.17.

31.1 Annihilating Polynomials and the Minimal Polynomial

Given a linear map $f: E \rightarrow E$, it is easy to check that the set $\text{Ann}(f)$ of polynomials that annihilate f is an ideal. Furthermore, when E is finite-dimensional, the Cayley–Hamilton Theorem implies that $\text{Ann}(f)$ is not the zero ideal. Therefore, by Proposition 30.10, there is a unique monic polynomial m_f that generates $\text{Ann}(f)$. Results from Chapter 30, especially about gcd's of polynomials, will come handy.

Definition 31.1. If $f: E \rightarrow E$ is a linear map on a finite-dimensional vector space E , the unique monic polynomial $m_f(X)$ that generates the ideal $\text{Ann}(f)$ of polynomials which annihilate f (the *annihilator* of f) is called the *minimal polynomial* of f .

The minimal polynomial m_f of f is the monic polynomial of smallest degree that annihilates f . Thus, the minimal polynomial divides the characteristic polynomial χ_f , and $\deg(m_f) \geq 1$. For simplicity of notation, we often write m instead of m_f .

If A is any $n \times n$ matrix, the set $\text{Ann}(A)$ of polynomials that annihilate A is the set of polynomials

$$p(X) = a_0X^d + a_1X^{d-1} + \cdots + a_{d-1}X + a_d$$

such that

$$a_0A^d + a_1A^{d-1} + \cdots + a_{d-1}A + a_dI = 0.$$

It is clear that $\text{Ann}(A)$ is a nonzero ideal and its unique monic generator is called the *minimal polynomial* of A . We check immediately that if Q is an invertible matrix, then A and $Q^{-1}AQ$ have the same minimal polynomial. Also, if A is the matrix of f with respect to some basis, then f and A have the same minimal polynomial.

The zeros (in K) of the minimal polynomial of f and the eigenvalues of f (in K) are intimately related.

Proposition 31.1. *Let $f: E \rightarrow E$ be a linear map on some finite-dimensional vector space E . Then $\lambda \in K$ is a zero of the minimal polynomial $m_f(X)$ of f iff λ is an eigenvalue of f*

iff λ is a zero of $\chi_f(X)$. Therefore, the minimal and the characteristic polynomials have the same zeros (in K), except for multiplicities.

Proof. First assume that $m(\lambda) = 0$ (with $\lambda \in K$, and writing m instead of m_f). If so, using polynomial division, m can be factored as

$$m = (X - \lambda)q,$$

with $\deg(q) < \deg(m)$. Since m is the minimal polynomial, $q(f) \neq 0$, so there is some nonzero vector $v \in E$ such that $u = q(f)(v) \neq 0$. But then, because m is the minimal polynomial,

$$\begin{aligned} 0 &= m(f)(v) \\ &= (f - \lambda \text{id})(q(f)(v)) \\ &= (f - \lambda \text{id})(u), \end{aligned}$$

which shows that λ is an eigenvalue of f .

Conversely, assume that $\lambda \in K$ is an eigenvalue of f . This means that for some $u \neq 0$, we have $f(u) = \lambda u$. Now it is easy to show that

$$m(f)(u) = m(\lambda)u,$$

and since m is the minimal polynomial of f , we have $m(f)(u) = 0$, so $m(\lambda)u = 0$, and since $u \neq 0$, we must have $m(\lambda) = 0$. \square

Proposition 31.2. *Let $f: E \rightarrow E$ be a linear map on some finite-dimensional vector space E . If f diagonalizable, then its minimal polynomial is a product of distinct factors of degree 1.*

Proof. If we assume that f is diagonalizable, then its eigenvalues are all in K , and if $\lambda_1, \dots, \lambda_k$ are the distinct eigenvalues of f , and then by Proposition 31.1, the minimal polynomial m of f must be a product of powers of the polynomials $(X - \lambda_i)$. Actually, we claim that

$$m = (X - \lambda_1) \cdots (X - \lambda_k).$$

For this we just have to show that m annihilates f . However, for any eigenvector u of f , one of the linear maps $f - \lambda_i \text{id}$ sends u to 0, so

$$m(f)(u) = (f - \lambda_1 \text{id}) \circ \cdots \circ (f - \lambda_k \text{id})(u) = 0.$$

Since E is spanned by the eigenvectors of f , we conclude that

$$m(f) = 0. \quad \square$$

It turns out that the converse of Proposition 31.2 is true, but this will take a little work to establish it.

31.2 Minimal Polynomials of Diagonalizable Linear Maps

In this section we prove that if the minimal polynomial m_f of a linear map f is of the form

$$m_f = (X - \lambda_1) \cdots (X - \lambda_k)$$

for distinct scalars $\lambda_1, \dots, \lambda_k \in K$, then f is diagonalizable. This is a powerful result that has a number of implications. But first we need of few properties of invariant subspaces.

Given a linear map $f: E \rightarrow E$, recall that a subspace W of E is *invariant under f* if $f(u) \in W$ for all $u \in W$. For example, if $f: \mathbb{R}^2 \rightarrow \mathbb{R}^2$ is $f(x, y) = (-x, y)$, the y -axis is invariant under f .

Proposition 31.3. *Let W be a subspace of E invariant under the linear map $f: E \rightarrow E$ (where E is finite-dimensional). Then the minimal polynomial of the restriction $f|W$ of f to W divides the minimal polynomial of f , and the characteristic polynomial of $f|W$ divides the characteristic polynomial of f .*

Sketch of proof. The key ingredient is that we can pick a basis (e_1, \dots, e_n) of E in which (e_1, \dots, e_k) is a basis of W . The matrix of f over this basis is a block matrix of the form

$$A = \begin{pmatrix} B & C \\ 0 & D \end{pmatrix},$$

where B is a $k \times k$ matrix, D is an $(n-k) \times (n-k)$ matrix, and C is a $k \times (n-k)$ matrix. Then

$$\det(XI - A) = \det(XI - B) \det(XI - D),$$

which implies the statement about the characteristic polynomials. Furthermore,

$$A^i = \begin{pmatrix} B^i & C_i \\ 0 & D^i \end{pmatrix},$$

for some $k \times (n-k)$ matrix C_i . It follows that any polynomial which annihilates A also annihilates B and D . So the minimal polynomial of B divides the minimal polynomial of A . \square

For the next step, there are at least two ways to proceed. We can use an old-fashion argument using Lagrange interpolants, or we can use a slight generalization of the notion of annihilator. We pick the second method because it illustrates nicely the power of principal ideals.

What we need is the notion of conductor (also called transporter).

Definition 31.2. Let $f: E \rightarrow E$ be a linear map on a finite-dimensional vector space E , let W be an invariant subspace of f , and let u be any vector in E . The set $S_f(u, W)$ consisting of all polynomials $q \in K[X]$ such that $q(f)(u) \in W$ is called the *f -conductor of u into W* .

Observe that the minimal polynomial m_f of f always belongs to $S_f(u, W)$, so this is a nontrivial set. Also, if $W = (0)$, then $S_f(u, (0))$ is just the annihilator of f . The crucial property of $S_f(u, W)$ is that it is an ideal.

Proposition 31.4. *If W is an invariant subspace for f , then for each $u \in E$, the f -conductor $S_f(u, W)$ is an ideal in $K[X]$.*

We leave the proof as a simple exercise, using the fact that if W invariant under f , then W is invariant under every polynomial $q(f)$ in $S_f(u, W)$.

Since $S_f(u, W)$ is an ideal, it is generated by a unique monic polynomial q of smallest degree, and because the minimal polynomial m_f of f is in $S_f(u, W)$, the polynomial q divides m .

Definition 31.3. The unique monic polynomial which generates $S_f(u, W)$ is called the *conductor of u into W* .

Example 31.1. For example, suppose $f: \mathbb{R}^2 \rightarrow \mathbb{R}^2$ where $f(x, y) = (x, 0)$. Observe that $W = \{(x, 0) \in \mathbb{R}^2\}$ is invariant under f . By representing f as $\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$, we see that $m_f(X) = \chi_f(X) = X^2 - X$. Let $u = (0, y)$. Then $S_f(u, W) = (X)$ and we say X is the conductor of u into W .

Proposition 31.5. *Let $f: E \rightarrow E$ be a linear map on a finite-dimensional space E and assume that the minimal polynomial m of f is of the form*

$$m = (X - \lambda_1)^{r_1} \cdots (X - \lambda_k)^{r_k},$$

where the eigenvalues $\lambda_1, \dots, \lambda_k$ of f belong to K . If W is a proper subspace of E which is invariant under f , then there is a vector $u \in E$ with the following properties:

- (a) $u \notin W$;
- (b) $(f - \lambda_i \text{id})(u) \in W$, for some eigenvalue λ of f .

Proof. Observe that (a) and (b) together assert that the conductor of u into W is a polynomial of the form $X - \lambda_i$. Pick any vector $v \in E$ not in W , and let g be the conductor of v into W , i.e. $g(f)(v) \in W$. Since g divides m and $v \notin W$, the polynomial g is not a constant, and thus it is of the form

$$g = (X - \lambda_1)^{s_1} \cdots (X - \lambda_k)^{s_k},$$

with at least some $s_i > 0$. Choose some index j such that $s_j > 0$. Then $X - \lambda_j$ is a factor of g , so we can write

$$g = (X - \lambda_j)q. \tag{*}$$

By definition of g , the vector $u = g(f)(v)$ cannot be in W , since otherwise g would not be of minimal degree. However, $(*)$ implies that

$$\begin{aligned}(f - \lambda_j \text{id})(u) &= (f - \lambda_j \text{id})(q(f)(v)) \\ &= g(f)(v)\end{aligned}$$

is in W , which concludes the proof. \square

We can now prove the main result of this section.

Theorem 31.6. *Let $f: E \rightarrow E$ be a linear map on a finite-dimensional space E . Then f is diagonalizable iff its minimal polynomial m is of the form*

$$m = (X - \lambda_1) \cdots (X - \lambda_k),$$

where $\lambda_1, \dots, \lambda_k$ are distinct elements of K .

Proof. We already showed in Proposition 31.2 that if f is diagonalizable, then its minimal polynomial is of the above form (where $\lambda_1, \dots, \lambda_k$ are the distinct eigenvalues of f).

For the converse, let W be the subspace spanned by all the eigenvectors of f . If $W \neq E$, since W is invariant under f , by Proposition 31.5, there is some vector $u \notin W$ such that for some λ_j , we have

$$(f - \lambda_j \text{id})(u) \in W.$$

Let $v = (f - \lambda_j \text{id})(u) \in W$. Since $v \in W$, we can write

$$v = w_1 + \cdots + w_k$$

where $f(w_i) = \lambda_i w_i$ (either $w_i = 0$ or w_i is an eigenvector for λ_i), and so for every polynomial h , we have

$$h(f)(v) = h(\lambda_1)w_1 + \cdots + h(\lambda_k)w_k,$$

which shows that $h(f)(v) \in W$ for every polynomial h . We can write

$$m = (X - \lambda_j)q$$

for some polynomial q , and also

$$q - q(\lambda_j) = p(X - \lambda_j)$$

for some polynomial p . We know that $p(f)(v) \in W$, and since m is the minimal polynomial of f , we have

$$0 = m(f)(u) = (f - \lambda_j \text{id})(q(f)(u)),$$

which implies that $q(f)(u) \in W$ (either $q(f)(u) = 0$, or it is an eigenvector associated with λ_j). However,

$$q(f)(u) - q(\lambda_j)u = p(f)((f - \lambda_j \text{id})(u)) = p(f)(v),$$

and since $p(f)(v) \in W$ and $q(f)(u) \in W$, we conclude that $q(\lambda_j)u \in W$. But, $u \notin W$, which implies that $q(\lambda_j) = 0$, so λ_j is a double root of m , a contradiction. Therefore, we must have $W = E$. \square

Remark: Proposition 31.5 can be used to give a quick proof of Theorem 15.5.

31.3 Commuting Families of Diagonalizable and Triangularizable Maps

Using Theorem 31.6, we can give a short proof about commuting diagonalizable linear maps.

Definition 31.4. If \mathcal{F} is a family of linear maps on a vector space E , we say that \mathcal{F} is a *commuting family* iff $f \circ g = g \circ f$ for all $f, g \in \mathcal{F}$.

Proposition 31.7. *Let \mathcal{F} be a finite commuting family of diagonalizable linear maps on a vector space E . There exists a basis of E such that every linear map in \mathcal{F} is represented in that basis by a diagonal matrix.*

Proof. We proceed by induction on $n = \dim(E)$. If $n = 1$, there is nothing to prove. If $n > 1$, there are two cases. If all linear maps in \mathcal{F} are of the form λid for some $\lambda \in K$, then the proposition holds trivially. In the second case, let $f \in \mathcal{F}$ be some linear map in \mathcal{F} which is not a scalar multiple of the identity. In this case, f has at least two distinct eigenvalues $\lambda_1, \dots, \lambda_k$, and because f is diagonalizable, E is the direct sum of the corresponding eigenspaces $E_{\lambda_1}, \dots, E_{\lambda_k}$. For every index i , the eigenspace E_{λ_i} is invariant under f and under every other linear map g in \mathcal{F} , since for any $g \in \mathcal{F}$ and any $u \in E_{\lambda_i}$, because f and g commute, we have

$$f(g(u)) = g(f(u)) = g(\lambda_i u) = \lambda_i g(u)$$

so $g(u) \in E_{\lambda_i}$. Let \mathcal{F}_i be the family obtained by restricting each $f \in \mathcal{F}$ to E_{λ_i} . By Proposition 31.3, the minimal polynomial of every linear map $f \mid E_{\lambda_i}$ in \mathcal{F}_i divides the minimal polynomial m_f of f , and since f is diagonalizable, m_f is a product of distinct linear factors, so the minimal polynomial of $f \mid E_{\lambda_i}$ is also a product of distinct linear factors. By Theorem 31.6, the linear map $f \mid E_{\lambda_i}$ is diagonalizable. Since $k > 1$, we have $\dim(E_{\lambda_i}) < \dim(E)$ for $i = 1, \dots, k$, and by the induction hypothesis, for each i there is a basis of E_{λ_i} over which $f \mid E_{\lambda_i}$ is represented by a diagonal matrix. Since the above argument holds for all i , by combining the bases of the E_{λ_i} , we obtain a basis of E such that the matrix of every linear map $f \in \mathcal{F}$ is represented by a diagonal matrix. \square

Remark: Proposition 31.7 also holds for infinite commuting families \mathcal{F} of diagonalizable linear maps, because E being finite dimensional, there is a finite subfamily of linearly independent linear maps in \mathcal{F} spanning \mathcal{F} .

There is also an analogous result for commuting families of linear maps represented by upper triangular matrices. To prove this we need the following proposition.

Proposition 31.8. *Let \mathcal{F} be a nonempty finite commuting family of triangulable linear maps on a finite-dimensional vector space E . Let W be a proper subspace of E which is invariant under \mathcal{F} . Then there exists a vector $u \in E$ such that:*

1. $u \notin W$.
2. For every $f \in \mathcal{F}$, the vector $f(u)$ belongs to the subspace $W \oplus Ku$ spanned by W and u .

Proof. By renaming the elements of \mathcal{F} if necessary, we may assume that (f_1, \dots, f_r) is a basis of the subspace of $\text{End}(E)$ spanned by \mathcal{F} . We prove by induction on r that there exists some vector $u \in E$ such that

1. $u \notin W$.
2. $(f_i - \alpha_i \text{id})(u) \in W$ for $i = 1, \dots, r$, for some scalars $\alpha_i \in K$.

Consider the base case $r = 1$. Since f_1 is triangulable, its eigenvalues all belong to K since they are the diagonal entries of the triangular matrix associated with f_1 (this is the easy direction of Theorem 15.5), so the minimal polynomial of f_1 is of the form

$$m = (X - \lambda_1)^{r_1} \cdots (X - \lambda_k)^{r_k},$$

where the eigenvalues $\lambda_1, \dots, \lambda_k$ of f_1 belong to K . We conclude by applying Proposition 31.5.

Next assume that $r \geq 2$ and that the induction hypothesis holds for f_1, \dots, f_{r-1} . Thus, there is a vector $u_{r-1} \in E$ such that

1. $u_{r-1} \notin W$.
2. $(f_i - \alpha_i \text{id})(u_{r-1}) \in W$ for $i = 1, \dots, r-1$, for some scalars $\alpha_i \in K$.

Let

$$V_{r-1} = \{w \in E \mid (f_i - \alpha_i \text{id})(w) \in W, i = 1, \dots, r-1\}.$$

Clearly, $W \subseteq V_{r-1}$ and $u_{r-1} \in V_{r-1}$. We claim that V_{r-1} is invariant under \mathcal{F} . This is because, for any $v \in V_{r-1}$ and any $f \in \mathcal{F}$, since f and f_i commute, we have

$$(f_i - \alpha_i \text{id})(f(v)) = f((f_i - \alpha_i \text{id})(v)), \quad 1 \leq i \leq r-1.$$

Now $(f_i - \alpha_i \text{id})(v) \in W$ because $v \in V_{r-1}$, and W is invariant under \mathcal{F} , so $f(f_i - \alpha_i \text{id})(v)) \in W$, that is, $(f_i - \alpha_i \text{id})(f(v)) \in W$.

Consider the restriction g_r of f_r to V_{r-1} . The minimal polynomial of g_r divides the minimal polynomial of f_r , and since f_r is triangulable, just as we saw for f_1 , the minimal polynomial of f_r is of the form

$$m = (X - \lambda_1)^{r_1} \cdots (X - \lambda_k)^{r_k},$$

where the eigenvalues $\lambda_1, \dots, \lambda_k$ of f_r belong to K , so the minimal polynomial of g_r is of the same form. By Proposition 31.5, there is some vector $u_r \in V_{r-1}$ such that

1. $u_r \notin W$.
2. $(g_r - \alpha_r \text{id})(u_r) \in W$ for some scalars $\alpha_r \in K$.

Now since $u_r \in V_{r-1}$, we have $(f_i - \alpha_i \text{id})(u_r) \in W$ for $i = 1, \dots, r-1$, so $(f_i - \alpha_i \text{id})(u_r) \in W$ for $i = 1, \dots, r$ (since g_r is the restriction of f_r), which concludes the proof of the induction step. Finally, since every $f \in \mathcal{F}$ is the linear combination of (f_1, \dots, f_r) , Condition (2) of the inductive claim implies Condition (2) of the proposition. \square

We can now prove the following result.

Proposition 31.9. *Let \mathcal{F} be a nonempty finite commuting family of triangulable linear maps on a finite-dimensional vector space E . There exists a basis of E such that every linear map in \mathcal{F} is represented in that basis by an upper triangular matrix.*

Proof. Let $n = \dim(E)$. We construct inductively a basis (u_1, \dots, u_n) of E such that if W_i is the subspace spanned by (u_1, \dots, u_i) , then for every $f \in \mathcal{F}$,

$$f(u_i) = a_{1i}^f u_1 + \cdots + a_{ii}^f u_i,$$

for some $a_{ij}^f \in K$; that is, $f(u_i)$ belongs to the subspace W_i .

We begin by applying Proposition 31.8 to the subspace $W_0 = (0)$ to get u_1 so that for all $f \in \mathcal{F}$,

$$f(u_1) = \alpha_1^f u_1.$$

For the induction step, since W_i invariant under \mathcal{F} , we apply Proposition 31.8 to the subspace W_i , to get $u_{i+1} \in E$ such that

1. $u_{i+1} \notin W_i$.
2. For every $f \in \mathcal{F}$, the vector $f(u_{i+1})$ belong to the subspace spanned by W_i and u_{i+1} .

Condition (1) implies that $(u_1, \dots, u_i, u_{i+1})$ is linearly independent, and Condition (2) means that for every $f \in \mathcal{F}$,

$$f(u_{i+1}) = a_{1i+1}^f u_1 + \cdots + a_{i+1i+1}^f u_{i+1},$$

for some $a_{i+1j}^f \in K$, establishing the induction step. After n steps, each $f \in \mathcal{F}$ is represented by an upper triangular matrix. \square

Observe that if \mathcal{F} consists of a single linear map f and if the minimal polynomial of f is of the form

$$m = (X - \lambda_1)^{r_1} \cdots (X - \lambda_k)^{r_k},$$

with all $\lambda_i \in K$, using Proposition 31.5 instead of Proposition 31.8, the proof of Proposition 31.9 yields another proof of Theorem 15.5.

31.4 The Primary Decomposition Theorem

If $f: E \rightarrow E$ is a linear map and $\lambda \in K$ is an eigenvalue of f , recall that the eigenspace E_λ associated with λ is the kernel of the linear map $\lambda \text{id} - f$. If all the eigenvalues $\lambda_1, \dots, \lambda_k$ of f are in K , it may happen that

$$E = E_{\lambda_1} \oplus \cdots \oplus E_{\lambda_k},$$

but in general there are not enough eigenvectors to span E . What if we generalize the notion of eigenvector and look for (nonzero) vectors u such that

$$(\lambda \text{id} - f)^r(u) = 0, \quad \text{for some } r \geq 1?$$

It turns out that if the minimal polynomial of f is of the form

$$m = (X - \lambda_1)^{r_1} \cdots (X - \lambda_k)^{r_k},$$

then $r = r_i$ does the job for λ_i ; that is, if we let

$$W_i = \text{Ker}(\lambda_i \text{id} - f)^{r_i},$$

then

$$E = W_1 \oplus \cdots \oplus W_k.$$

This result is very nice but seems to require that the eigenvalues of f all belong to K . Actually, it is a special case of a more general result involving the factorization of the minimal polynomial m into its irreducible monic factors (see Theorem 30.17),

$$m = p_1^{r_1} \cdots p_k^{r_k},$$

where the p_i are distinct irreducible monic polynomials over K .

Theorem 31.10. (Primary Decomposition Theorem) *Let $f: E \rightarrow E$ be a linear map on the finite-dimensional vector space E over the field K . Write the minimal polynomial m of f as*

$$m = p_1^{r_1} \cdots p_k^{r_k},$$

where the p_i are distinct irreducible monic polynomials over K , and the r_i are positive integers. Let

$$W_i = \text{Ker}(p_i^{r_i}(f)), \quad i = 1, \dots, k.$$

Then

- (a) $E = W_1 \oplus \cdots \oplus W_k$.
- (b) *Each W_i is invariant under f .*
- (c) *The minimal polynomial of the restriction $f|_{W_i}$ of f to W_i is $p_i^{r_i}$.*

Proof. The trick is to construct projections π_i using the polynomials $p_j^{r_j}$ so that the range of π_i is equal to W_i . Let

$$g_i = m/p_i^{r_i} = \prod_{j \neq i} p_j^{r_j}.$$

Note that

$$p_i^{r_i} g_i = m.$$

Since p_1, \dots, p_k are irreducible and distinct, they are relatively prime. Then using Proposition 30.14, it is easy to show that g_1, \dots, g_k are relatively prime. Otherwise, some irreducible polynomial p would divide all of g_1, \dots, g_k , so by Proposition 30.14 it would be equal to one of the irreducible factors p_i . But that p_i is missing from g_i , a contradiction. Therefore, by Proposition 30.15, there exist some polynomials h_1, \dots, h_k such that

$$g_1 h_1 + \cdots + g_k h_k = 1.$$

Let $q_i = g_i h_i$ and let $\pi_i = q_i(f) = g_i(f)h_i(f)$. We have

$$q_1 + \cdots + q_k = 1,$$

and since m divides $q_i q_j$ for $i \neq j$, we get

$$\begin{aligned} \pi_1 + \cdots + \pi_k &= \text{id} \\ \pi_i \pi_j &= 0, \quad i \neq j. \end{aligned}$$

(We implicitly used the fact that if p, q are two polynomials, the linear maps $p(f) \circ q(f)$ and $q(f) \circ p(f)$ are the same since $p(f)$ and $q(f)$ are polynomials in the powers of f , which commute.) Composing the first equation with π_i and using the second equation, we get

$$\pi_i^2 = \pi_i.$$

Therefore, the π_i are projections, and E is the direct sum of the images of the π_i . Indeed, every $u \in E$ can be expressed as

$$u = \pi_1(u) + \cdots + \pi_k(u).$$

Also, if

$$\pi_1(u) + \cdots + \pi_k(u) = 0,$$

then by applying π_i we get

$$0 = \pi_i^2(u) = \pi_i(u), \quad i = 1, \dots, k.$$

To finish proving (a), we need to show that

$$W_i = \text{Ker}(p_i^{r_i}(f)) = \pi_i(E).$$

If $v \in \pi_i(E)$, then $v = \pi_i(u)$ for some $u \in E$, so

$$\begin{aligned} p_i^{r_i}(f)(v) &= p_i^{r_i}(f)(\pi_i(u)) \\ &= p_i^{r_i}(f)g_i(f)h_i(f)(u) \\ &= h_i(f)p_i^{r_i}(f)g_i(f)(u) \\ &= h_i(f)m(f)(u) = 0, \end{aligned}$$

because m is the minimal polynomial of f . Therefore, $v \in W_i$.

Conversely, assume that $v \in W_i = \text{Ker}(p_i^{r_i}(f))$. If $j \neq i$, then $g_j h_j$ is divisible by $p_i^{r_i}$, so

$$g_j(f)h_j(f)(v) = \pi_j(v) = 0, \quad j \neq i.$$

Then since $\pi_1 + \cdots + \pi_k = \text{id}$, we have $v = \pi_i v$, which shows that v is in the range of π_i . Therefore, $W_i = \text{Im}(\pi_i)$, and this finishes the proof of (a).

If $p_i^{r_i}(f)(u) = 0$, then $p_i^{r_i}(f)(f(u)) = f(p_i^{r_i}(f)(u)) = 0$, so (b) holds.

If we write $f_i = f|_{W_i}$, then $p_i^{r_i}(f_i) = 0$, because $p_i^{r_i}(f) = 0$ on W_i (its kernel). Therefore, the minimal polynomial of f_i divides $p_i^{r_i}$. Conversely, let q be any polynomial such that $q(f_i) = 0$ (on W_i). Since $m = p_i^{r_i}g_i$, the fact that $m(f)(u) = 0$ for all $u \in E$ shows that

$$p_i^{r_i}(f)(g_i(f)(u)) = 0, \quad u \in E,$$

and thus $\text{Im}(g_i(f)) \subseteq \text{Ker}(p_i^{r_i}(f)) = W_i$. Consequently, since $q(f)$ is zero on W_i ,

$$q(f)g_i(f) = 0 \quad \text{for all } u \in E.$$

But then qg_i is divisible by the minimal polynomial $m = p_i^{r_i}g_i$ of f , and since $p_i^{r_i}$ and g_i are relatively prime, by Euclid's proposition, $p_i^{r_i}$ must divide q . This finishes the proof that the minimal polynomial of f_i is $p_i^{r_i}$, which is (c). \square

To best understand the projection constructions of Theorem 31.10, we provide the following two explicit examples of the primary decomposition theorem.

Example 31.2. First let $f: \mathbb{R}^3 \rightarrow \mathbb{R}^3$ be defined as $f(x, y, z) = (y, -x, z)$. In terms of the standard basis f is represented by the 3×3 matrix $X_f := \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}$. Then a simple calculation shows that $m_f(x) = \chi_f(x) = (x^2 + 1)(x - 1)$. Using the notation of the preceding proof set

$$m = p_1 p_2, \quad p_1 = x^2 + 1, \quad p_2 = x - 1.$$

Then

$$g_1 = \frac{m}{p_1} = x - 1, \quad g_2 = \frac{m}{p_2} = x^2 + 1.$$

We must find $h_1, h_2 \in \mathbb{R}[x]$ such that $g_1 h_1 + g_2 h_2 = 1$. In general this is the hard part of the projection construction. But since we are only working with two relatively prime polynomials g_1, g_2 , we may apply the Euclidean algorithm to discover that

$$-\frac{x+1}{2}(x-1) + \frac{1}{2}(x^2+1) = 1,$$

where $h_1 = -\frac{x+1}{2}$ while $h_2 = \frac{1}{2}$. By definition

$$\pi_1 = g_1(f)h_1(f) = -\frac{1}{2}(X_f - \text{id})(X_f + \text{id}) = -\frac{1}{2}(X_f^2 - \text{id}) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix},$$

and

$$\pi_2 = g_2(f)h_2(f) = \frac{1}{2}(X_f^2 + \text{id}) = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

Then $\mathbb{R}^3 = W_1 \oplus W_2$, where

$$W_1 = \pi_1(\mathbb{R}^3) = \text{Ker}(p_1(X_f)) = \text{Ker}(X_f^2 + \text{id}) = \text{Ker} \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} = \{(x, y, 0) \in \mathbb{R}^3\},$$

$$W_2 = \pi_2(\mathbb{R}^3) = \text{Ker}(p_2(X_f)) = \text{Ker}(X_f - \text{id}) = \text{Ker} \begin{pmatrix} -1 & -1 & 0 \\ 1 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix} = \{(0, 0, z) \in \mathbb{R}^3\}.$$

Example 31.3. For our second example of the primary decomposition theorem let $f: \mathbb{R}^3 \rightarrow \mathbb{R}^3$ be defined as $f(x, y, z) = (y, -x + z, -y)$, with standard matrix representation $X_f = \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & -1 \\ 0 & 1 & 0 \end{pmatrix}$. A simple calculation shows that $m_f(x) = \chi_f(x) = x(x^2 + 2)$. Set

$$p_1 = x^2 + 2, \quad p_2 = x, \quad g_1 = \frac{m_f}{p_1} = x, \quad g_2 = \frac{m_f}{p_2} = x^2 + 2.$$

Since $\gcd(g_1, g_2) = 1$, we use the Euclidean algorithm to find

$$h_1 = -\frac{1}{2}x, \quad h_2 = \frac{1}{2},$$

such that $g_1 h_1 + g_2 h_2 = 1$. Then

$$\pi_1 = g_1(f)h_1(f) = -\frac{1}{2}X_f^2 = \begin{pmatrix} \frac{1}{2} & 0 & -\frac{1}{2} \\ 0 & 1 & 0 \\ -\frac{1}{2} & 0 & \frac{1}{2} \end{pmatrix},$$

while

$$\pi_2 = g_2(f)h_2(f) = \frac{1}{2}(X_f^2 + 2\text{id}) = \begin{pmatrix} \frac{1}{2} & 0 & \frac{1}{2} \\ 0 & 0 & 0 \\ \frac{1}{2} & 0 & \frac{1}{2} \end{pmatrix}.$$

Although it is not entirely obvious, π_1 and π_2 are indeed projections since

$$\pi_1^2 = \begin{pmatrix} \frac{1}{2} & 0 & -\frac{1}{2} \\ 0 & 1 & 0 \\ -\frac{1}{2} & 0 & \frac{1}{2} \end{pmatrix} \begin{pmatrix} \frac{1}{2} & 0 & -\frac{1}{2} \\ 0 & 1 & 0 \\ -\frac{1}{2} & 0 & \frac{1}{2} \end{pmatrix} = \begin{pmatrix} \frac{1}{2} & 0 & -\frac{1}{2} \\ 0 & 1 & 0 \\ -\frac{1}{2} & 0 & \frac{1}{2} \end{pmatrix} = \pi_1,$$

and

$$\pi_2^2 = \begin{pmatrix} \frac{1}{2} & 0 & \frac{1}{2} \\ 0 & 0 & 0 \\ \frac{1}{2} & 0 & \frac{1}{2} \end{pmatrix} \begin{pmatrix} \frac{1}{2} & 0 & \frac{1}{2} \\ 0 & 0 & 0 \\ \frac{1}{2} & 0 & \frac{1}{2} \end{pmatrix} = \begin{pmatrix} \frac{1}{2} & 0 & \frac{1}{2} \\ 0 & 0 & 0 \\ \frac{1}{2} & 0 & \frac{1}{2} \end{pmatrix} = \pi_2.$$

Furthermore observe that $\pi_1 + \pi_2 = \text{id}$. The primary decomposition theorem implies that $\mathbb{R}^3 = W_1 \oplus W_2$ where

$$W_1 = \pi_1(\mathbb{R}^3) = \text{Ker}(p_1(f)) = \text{Ker}(X^2 + 2) = \text{Ker} \begin{pmatrix} 1 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 1 \end{pmatrix} = \text{span}\{(0, 1, 0), (1, 0, -1)\},$$

$$W_2 = \pi_2(\mathbb{R}^3) = \text{Ker}(p_2(f)) = \text{Ker}(X) = \text{span}\{(1, 0, 1)\}.$$

See Figure 31.1.

If all the eigenvalues of f belong to the field K , we obtain the following result.

Theorem 31.11. (*Primary Decomposition Theorem, Version 2*) *Let $f: E \rightarrow E$ be a linear map on the finite-dimensional vector space E over the field K . If all the eigenvalues $\lambda_1, \dots, \lambda_k$ of f belong to K , write*

$$m = (X - \lambda_1)^{r_1} \cdots (X - \lambda_k)^{r_k}$$

for the minimal polynomial of f ,

$$\chi_f = (X - \lambda_1)^{n_1} \cdots (X - \lambda_k)^{n_k}$$

for the characteristic polynomial of f , with $1 \leq r_i \leq n_i$, and let

$$W_i = \text{Ker}(\lambda_i \text{id} - f)^{r_i}, \quad i = 1, \dots, k.$$

Then

$$(a) \quad E = W_1 \oplus \cdots \oplus W_k.$$

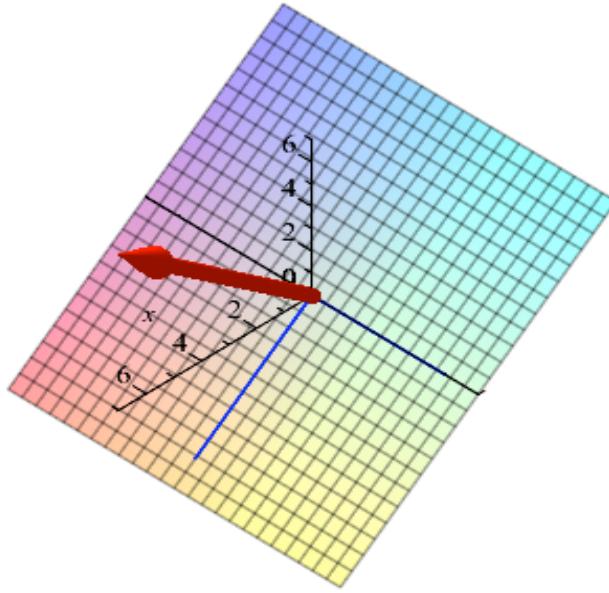

Figure 31.1: The direct sum decomposition of $\mathbb{R}^3 = W_1 \oplus W_2$ where W_1 is the plane $x + z = 0$ and W_2 is line $t(1, 0, 1)$. The spanning vectors of W_1 are in blue.

- (b) Each W_i is invariant under f .
- (c) $\dim(W_i) = n_i$.
- (d) The minimal polynomial of the restriction $f|_{W_i}$ of f to W_i is $(X - \lambda_i)^{r_i}$.

Proof. Parts (a), (b) and (d) have already been proven in Theorem 31.10, so it remains to prove (c). Since W_i is invariant under f , let f_i be the restriction of f to W_i . The characteristic polynomial χ_{f_i} of f_i divides $\chi(f)$, and since $\chi(f)$ has all its roots in K , so does $\chi_i(f)$. By Theorem 15.5, there is a basis of W_i in which f_i is represented by an upper triangular matrix, and since $(\lambda_i \text{id} - f)^{r_i} = 0$, the diagonal entries of this matrix are equal to λ_i . Consequently,

$$\chi_{f_i} = (X - \lambda_i)^{\dim(W_i)},$$

and since χ_{f_i} divides $\chi(f)$, we conclude that

$$\dim(W_i) \leq n_i, \quad i = 1, \dots, k.$$

Because E is the direct sum of the W_i , we have $\dim(W_1) + \dots + \dim(W_k) = n$, and since $n_1 + \dots + n_k = n$, we must have

$$\dim(W_i) = n_i, \quad i = 1, \dots, k,$$

proving (c). □

Definition 31.5. If $\lambda \in K$ is an eigenvalue of f , we define a *generalized eigenvector* of f as a nonzero vector $u \in E$ such that

$$(\lambda \text{id} - f)^r(u) = 0, \quad \text{for some } r \geq 1.$$

The *index* of λ is defined as the smallest $r \geq 1$ such that

$$\text{Ker}(\lambda \text{id} - f)^r = \text{Ker}(\lambda \text{id} - f)^{r+1}.$$

It is clear that $\text{Ker}(\lambda \text{id} - f)^i \subseteq \text{Ker}(\lambda \text{id} - f)^{i+1}$ for all $i \geq 1$. By Theorem 31.11(d), if $\lambda = \lambda_i$, the index of λ_i is equal to r_i .

31.5 Jordan Decomposition

Recall that a linear map $g: E \rightarrow E$ is said to be *nilpotent* if there is some positive integer r such that $g^r = 0$. Another important consequence of Theorem 31.11 is that f can be written as the sum of a diagonalizable and a nilpotent linear map (which commute). For example $f: \mathbb{R}^2 \rightarrow \mathbb{R}^2$ be the \mathbb{R} -linear map $f(x, y) = (x, x + y)$ with standard matrix representation $X_f = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$. A basic calculation shows that $m_f(x) = \chi_f(x) = (x - 1)^2$. By Theorem 31.6 we know that f is not diagonalizable over \mathbb{R} . But since the eigenvalue $\lambda_1 = 1$ of f does belong to \mathbb{R} , we may use the projection construction inherent within Theorem 31.11 to write $f = D + N$, where D is a diagonalizable linear map and N is a nilpotent linear map. The proof of Theorem 31.10 implies that

$$p_1^{r_1} = (x - 1)^2, \quad g_1 = 1 = h_1, \quad \pi_1 = g_1(f)h_1(f) = \text{id}.$$

Then

$$D = \lambda_1 \pi_1 = \text{id}, \quad N = f - D = f(x, y) - \text{id}(x, y) = (x, x + y) - (x, y) = (0, y),$$

which is equivalent to the matrix decomposition

$$X_f = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}.$$

This example suggests that the diagonal summand of f is related to the projection constructions associated with the proof of the primary decomposition theorem. If we write

$$D = \lambda_1 \pi_1 + \cdots + \lambda_k \pi_k,$$

where π_i is the projection from E onto the subspace W_i defined in the proof of Theorem 31.10, since

$$\pi_1 + \cdots + \pi_k = \text{id},$$

we have

$$f = f\pi_1 + \cdots + f\pi_k,$$

and so we get

$$N = f - D = (f - \lambda_1 \text{id})\pi_1 + \cdots + (f - \lambda_k \text{id})\pi_k.$$

We claim that $N = f - D$ is a nilpotent operator. Since by construction the π_i are polynomials in f , they commute with f , using the properties of the π_i , we get

$$N^r = (f - \lambda_1 \text{id})^r \pi_1 + \cdots + (f - \lambda_k \text{id})^r \pi_k.$$

Therefore, if $r = \max\{r_i\}$, we have $(f - \lambda_i \text{id})^r = 0$ for $i = 1, \dots, k$, which implies that

$$N^r = 0.$$

It remains to show that D is diagonalizable. Since N is a polynomial in f , it commutes with f , and thus with D . From

$$D = \lambda_1 \pi_1 + \cdots + \lambda_k \pi_k,$$

and

$$\pi_1 + \cdots + \pi_k = \text{id},$$

we see that

$$\begin{aligned} D - \lambda_i \text{id} &= \lambda_1 \pi_1 + \cdots + \lambda_k \pi_k - \lambda_i(\pi_1 + \cdots + \pi_k) \\ &= (\lambda_1 - \lambda_i)\pi_1 + \cdots + (\lambda_{i-1} - \lambda_i)\pi_{i-1} + (\lambda_{i+1} - \lambda_i)\pi_{i+1} + \cdots + (\lambda_k - \lambda_i)\pi_k. \end{aligned}$$

Since the projections π_j with $j \neq i$ vanish on W_i , the above equation implies that $D - \lambda_i \text{id}$ vanishes on W_i and that $(D - \lambda_i \text{id})(W_i) \subseteq W_i$, and thus that the minimal polynomial of D is

$$(X - \lambda_1) \cdots (X - \lambda_k).$$

Since the λ_i are distinct, by Theorem 31.6, the linear map D is diagonalizable.

In summary we have shown that when all the eigenvalues of f belong to K , there exist a diagonalizable linear map D and a nilpotent linear map N such that

$$\begin{aligned} f &= D + N \\ DN &= ND, \end{aligned}$$

and N and D are polynomials in f .

Definition 31.6. A decomposition of f as $f = D + N$ as above is called a *Jordan decomposition*.

In fact, we can prove more: the maps D and N are uniquely determined by f .

Theorem 31.12. (*Jordan Decomposition*) Let $f: E \rightarrow E$ be a linear map on the finite-dimensional vector space E over the field K . If all the eigenvalues $\lambda_1, \dots, \lambda_k$ of f belong to K , then there exist a diagonalizable linear map D and a nilpotent linear map N such that

$$\begin{aligned} f &= D + N \\ DN &= ND. \end{aligned}$$

Furthermore, D and N are uniquely determined by the above equations and they are polynomials in f .

Proof. We already proved the existence part. Suppose we also have $f = D' + N'$, with $D'N' = N'D'$, where D' is diagonalizable, N' is nilpotent, and both are polynomials in f . We need to prove that $D = D'$ and $N = N'$.

Since D' and N' commute with one another and $f = D' + N'$, we see that D' and N' commute with f . Then D' and N' commute with any polynomial in f ; hence they commute with D and N . From

$$D + N = D' + N',$$

we get

$$D - D' = N' - N,$$

and D, D', N, N' commute with one another. Since D and D' are both diagonalizable and commute, by Proposition 31.7, they are simultaneously diagonalizable, so $D - D'$ is diagonalizable. Since N and N' commute, by the binomial formula, for any $r \geq 1$,

$$(N' - N)^r = \sum_{j=0}^r (-1)^j \binom{r}{j} (N')^{r-j} N^j.$$

Since both N and N' are nilpotent, we have $N^{r_1} = 0$ and $(N')^{r_2} = 0$, for some $r_1, r_2 > 0$, so for $r \geq r_1 + r_2$, the right-hand side of the above expression is zero, which shows that $N' - N$ is nilpotent. (In fact, it is easy that $r_1 = r_2 = n$ works). It follows that $D - D' = N' - N$ is both diagonalizable and nilpotent. Clearly, the minimal polynomial of a nilpotent linear map is of the form X^r for some $r > 0$ (and $r \leq \dim(E)$). But $D - D'$ is diagonalizable, so its minimal polynomial has simple roots, which means that $r = 1$. Therefore, the minimal polynomial of $D - D'$ is X , which says that $D - D' = 0$, and then $N = N'$. \square

If K is an algebraically closed field, then Theorem 31.12 holds. This is the case when $K = \mathbb{C}$. This theorem reduces the study of linear maps (from E to itself) to the study of nilpotent operators. There is a special normal form for such operators which is discussed in the next section.

31.6 Nilpotent Linear Maps and Jordan Form

This section is devoted to a normal form for nilpotent maps. We follow Godement's exposition [76]. Let $f: E \rightarrow E$ be a nilpotent linear map on a finite-dimensional vector space over a field K , and assume that f is not the zero map. There is a smallest positive integer $r \geq 1$ such $f^r \neq 0$ and $f^{r+1} = 0$. Clearly, the polynomial X^{r+1} annihilates f , and it is the minimal polynomial of f since $f^r \neq 0$. It follows that $r + 1 \leq n = \dim(E)$. Let us define the subspaces N_i by

$$N_i = \text{Ker}(f^i), \quad i \geq 0.$$

Note that $N_0 = (0)$, $N_1 = \text{Ker}(f)$, and $N_{r+1} = E$. Also, it is obvious that

$$N_i \subseteq N_{i+1}, \quad i \geq 0.$$

Proposition 31.13. *Given a nilpotent linear map f with $f^r \neq 0$ and $f^{r+1} = 0$ as above, the inclusions in the following sequence are strict:*

$$(0) = N_0 \subset N_1 \subset \cdots \subset N_r \subset N_{r+1} = E.$$

Proof. We proceed by contradiction. Assume that $N_i = N_{i+1}$ for some i with $0 \leq i \leq r$. Since $f^{r+1} = 0$, for every $u \in E$, we have

$$0 = f^{r+1}(u) = f^{i+1}(f^{r-i}(u)),$$

which shows that $f^{r-i}(u) \in N_{i+1}$. Since $N_i = N_{i+1}$, we get $f^{r-i}(u) \in N_i$, and thus $f^r(u) = 0$. Since this holds for all $u \in E$, we see that $f^r = 0$, a contradiction. \square

Proposition 31.14. *Given a nilpotent linear map f with $f^r \neq 0$ and $f^{r+1} = 0$, for any integer i with $1 \leq i \leq r$, for any subspace U of E , if $U \cap N_i = (0)$, then $f(U) \cap N_{i-1} = (0)$, and the restriction of f to U is an isomorphism onto $f(U)$.*

Proof. Pick $v \in f(U) \cap N_{i-1}$. We have $v = f(u)$ for some $u \in U$ and $f^{i-1}(v) = 0$, which means that $f^i(u) = 0$. Then $u \in U \cap N_i$, so $u = 0$ since $U \cap N_i = (0)$, and $v = f(u) = 0$. Therefore, $f(U) \cap N_{i-1} = (0)$. The restriction of f to U is obviously surjective on $f(U)$. Suppose that $f(u) = 0$ for some $u \in U$. Then $u \in U \cap N_1 \subseteq U \cap N_i = (0)$ (since $i \geq 1$), so $u = 0$, which proves that f is also injective on U . \square

Proposition 31.15. *Given a nilpotent linear map f with $f^r \neq 0$ and $f^{r+1} = 0$, there exists a sequence of subspaces U_1, \dots, U_{r+1} of E with the following properties:*

(1) $N_i = N_{i-1} \oplus U_i$, for $i = 1, \dots, r+1$.

(2) We have $f(U_i) \subseteq U_{i-1}$, and the restriction of f to U_i is an injection, for $i = 2, \dots, r+1$.

See Figure 31.2.

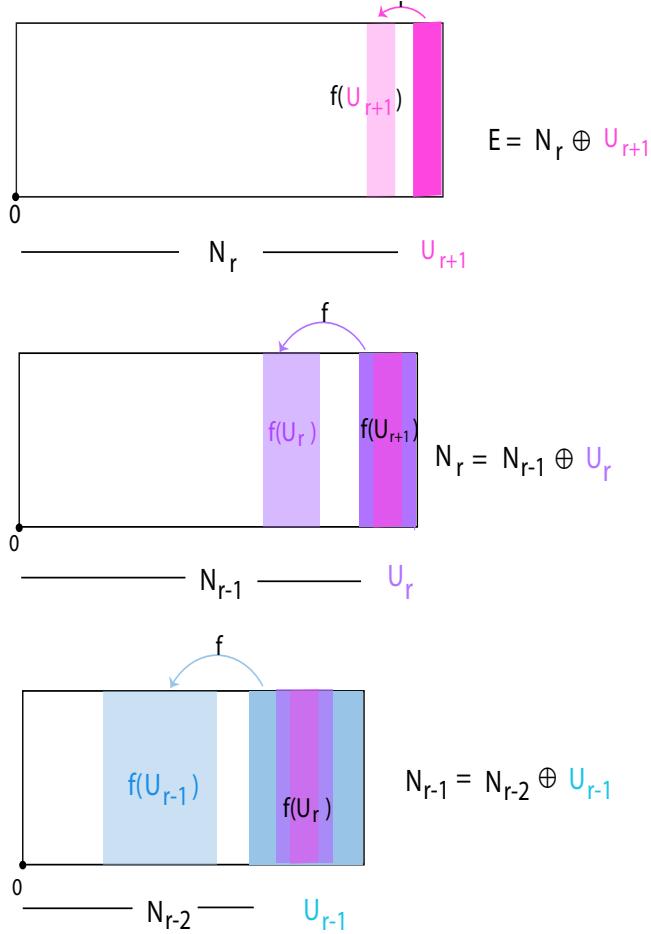

Figure 31.2: A schematic illustration of $N_i = N_{i-1} \oplus U_i$ with $f(U_i) \subseteq U_{i-1}$ for $i = r+1, r, r-1$.

Proof. We proceed inductively, by defining the sequence U_{r+1}, U_r, \dots, U_1 . We pick U_{r+1} to be any supplement of N_r in $N_{r+1} = E$, so that

$$E = N_{r+1} = N_r \oplus U_{r+1}.$$

Since $f^{r+1} = 0$ and $N_r = \text{Ker}(f^r)$, we have $f(U_{r+1}) \subseteq N_r$, and by Proposition 31.14, as $U_{r+1} \cap N_r = (0)$, we have $f(U_{r+1}) \cap N_{r-1} = (0)$. As a consequence, we can pick a supplement U_r of N_{r-1} in N_r so that $f(U_{r+1}) \subseteq U_r$. We have

$$N_r = N_{r-1} \oplus U_r \quad \text{and} \quad f(U_{r+1}) \subseteq U_r.$$

By Proposition 31.14, f is an injection from U_{r+1} to U_r . Assume inductively that U_{r+1}, \dots, U_i have been defined for $i \geq 2$ and that they satisfy (1) and (2). Since

$$N_i = N_{i-1} \oplus U_i,$$

we have $U_i \subseteq N_i$, so $f^{i-1}(f(U_i)) = f^i(U_i) = (0)$, which implies that $f(U_i) \subseteq N_{i-1}$. Also, since $U_i \cap N_{i-1} = (0)$, by Proposition 31.14, we have $f(U_i) \cap N_{i-2} = (0)$. It follows that there is a supplement U_{i-1} of N_{i-2} in N_{i-1} that contains $f(U_i)$. We have

$$N_{i-1} = N_{i-2} \oplus U_{i-1} \quad \text{and} \quad f(U_i) \subseteq U_{i-1}.$$

The fact that f is an injection from U_i into U_{i-1} follows from Proposition 31.14. Therefore, the induction step is proven. The construction stops when $i = 1$. \square

Because $N_0 = (0)$ and $N_{r+1} = E$, we see that E is the direct sum of the U_i :

$$E = U_1 \oplus \cdots \oplus U_{r+1},$$

with $f(U_i) \subseteq U_{i-1}$, and f an injection from U_i to U_{i-1} , for $i = r+1, \dots, 2$. By a clever choice of bases in the U_i , we obtain the following nice theorem.

Theorem 31.16. *For any nilpotent linear map $f: E \rightarrow E$ on a finite-dimensional vector space E of dimension n over a field K , there is a basis of E such that the matrix N of f is of the form*

$$N = \begin{pmatrix} 0 & \nu_1 & 0 & \cdots & 0 & 0 \\ 0 & 0 & \nu_2 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 0 & \nu_n \\ 0 & 0 & 0 & \cdots & 0 & 0 \end{pmatrix},$$

where $\nu_i = 1$ or $\nu_i = 0$.

Proof. First apply Proposition 31.15 to obtain a direct sum $E = \bigoplus_{i=1}^{r+1} U_i$. Then we define a basis of E inductively as follows. First we choose a basis

$$e_1^{r+1}, \dots, e_{n_{r+1}}^{r+1}$$

of U_{r+1} . Next, for $i = r+1, \dots, 2$, given the basis

$$e_1^i, \dots, e_{n_i}^i$$

of U_i , since f is injective on U_i and $f(U_i) \subseteq U_{i-1}$, the vectors $f(e_1^i), \dots, f(e_{n_i}^i)$ are linearly independent, so we define a basis of U_{i-1} by completing $f(e_1^i), \dots, f(e_{n_i}^i)$ to a basis in U_{i-1} :

$$e_1^{i-1}, \dots, e_{n_i}^{i-1}, e_{n_i+1}^{i-1}, \dots, e_{n_{i-1}}^{i-1}$$

with

$$e_j^{i-1} = f(e_j^i), \quad j = 1, \dots, n_i.$$

Since $U_1 = N_1 = \text{Ker}(f)$, we have

$$f(e_j^1) = 0, \quad j = 1, \dots, n_1.$$

These basis vectors can be arranged as the rows of the following matrix:

$$\begin{pmatrix} e_1^{r+1} & \cdots & e_{n_{r+1}}^{r+1} \\ \vdots & & \vdots \\ e_1^r & \cdots & e_{n_{r+1}}^r & e_{n_{r+1}+1}^r & \cdots & e_{n_r}^r \\ \vdots & & \vdots & \vdots & & \vdots \\ e_1^{r-1} & \cdots & e_{n_{r+1}}^{r-1} & e_{n_{r+1}+1}^{r-1} & \cdots & e_{n_r}^{r-1} & e_{n_{r+1}}^{r-1} & \cdots & e_{n_{r-1}}^{r-1} \\ \vdots & & \vdots & \vdots & & \vdots & \vdots & & \vdots \\ \vdots & & \vdots & \vdots & & \vdots & \vdots & & \vdots \\ e_1^1 & \cdots & e_{n_{r+1}}^1 & e_{n_{r+1}+1}^1 & \cdots & e_{n_r}^1 & e_{n_{r+1}}^1 & \cdots & e_{n_{r-1}}^1 & \cdots & \cdots & e_{n_1}^1 \end{pmatrix}$$

Finally, we define the basis (e_1, \dots, e_n) by listing each column of the above matrix from the bottom-up, starting with column one, then column two, etc. This means that we list the vectors e_j^i in the following order:

For $j = 1, \dots, n_{r+1}$, list e_j^1, \dots, e_j^{r+1} ;

In general, for $i = r, \dots, 1$,

for $j = n_{i+1} + 1, \dots, n_i$, list e_j^1, \dots, e_j^i .

Then because $f(e_j^1) = 0$ and $e_j^{i-1} = f(e_j^i)$ for $i \geq 2$, either

$$f(e_i) = 0 \quad \text{or} \quad f(e_i) = e_{i-1},$$

which proves the theorem. \square

As an application of Theorem 31.16, we obtain the *Jordan form* of a linear map.

Definition 31.7. A *Jordan block* is an $r \times r$ matrix $J_r(\lambda)$, of the form

$$J_r(\lambda) = \begin{pmatrix} \lambda & 1 & 0 & \cdots & 0 \\ 0 & \lambda & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & 0 & \ddots & 1 \\ 0 & 0 & 0 & \cdots & \lambda \end{pmatrix},$$

where $\lambda \in K$, with $J_1(\lambda) = (\lambda)$ if $r = 1$. A *Jordan matrix*, J , is an $n \times n$ block diagonal matrix of the form

$$J = \begin{pmatrix} J_{r_1}(\lambda_1) & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & J_{r_m}(\lambda_m) \end{pmatrix},$$

where each $J_{r_k}(\lambda_k)$ is a Jordan block associated with some $\lambda_k \in K$, and with $r_1 + \cdots + r_m = n$.

To simplify notation, we often write $J(\lambda)$ for $J_r(\lambda)$. Here is an example of a Jordan matrix with four blocks:

$$J = \begin{pmatrix} \lambda & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \lambda & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & \lambda & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \lambda & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \lambda & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & \lambda & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & \mu & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & \mu & \mu \end{pmatrix}.$$

Theorem 31.17. (Jordan form) *Let E be a vector space of dimension n over a field K and let $f: E \rightarrow E$ be a linear map. The following properties are equivalent:*

- (1) *The eigenvalues of f all belong to K (i.e. the roots of the characteristic polynomial χ_f all belong to K).*
- (2) *There is a basis of E in which the matrix of f is a Jordan matrix.*

Proof. Assume (1). First we apply Theorem 31.11, and we get a direct sum $E = \bigoplus_{j=1}^k W_k$, such that the restriction of $g_i = f - \lambda_j \text{id}$ to W_i is nilpotent. By Theorem 31.16, there is a basis of W_i such that the matrix of the restriction of g_i is of the form

$$G_i = \begin{pmatrix} 0 & \nu_1 & 0 & \cdots & 0 & 0 \\ 0 & 0 & \nu_2 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 0 & \nu_{n_i} \\ 0 & 0 & 0 & \cdots & 0 & 0 \end{pmatrix},$$

where $\nu_i = 1$ or $\nu_i = 0$. Furthermore, over any basis, $\lambda_i \text{id}$ is represented by the diagonal matrix D_i with λ_i on the diagonal. Then it is clear that we can split $D_i + G_i$ into Jordan blocks by forming a Jordan block for every uninterrupted chain of 1s. By putting the bases of the W_i together, we obtain a matrix in Jordan form for f .

Now assume (2). If f can be represented by a Jordan matrix, it is obvious that the diagonal entries are the eigenvalues of f , so they all belong to K . \square

Observe that Theorem 31.17 applies if $K = \mathbb{C}$. It turns out that there are uniqueness properties of the Jordan blocks. There are also other fundamental normal forms for linear maps, such as the rational canonical form, but to prove these results, it is better to develop more powerful machinery about finitely generated modules over a PID. To accomplish this most effectively, we need some basic knowledge about tensor products.

If a complex $n \times n$ matrix A is expressed in terms of its Jordan decomposition as $A = D + N$, since D and N commute, by Proposition 9.21, the exponential of A is given by

$$e^A = e^D e^N,$$

and since N is an $n \times n$ nilpotent matrix, $N^{n-1} = 0$, so we obtain

$$e^A = e^D \left(I + \frac{N}{1!} + \frac{N^2}{2!} + \cdots + \frac{N^{n-1}}{(n-1)!} \right).$$

In particular, the above applies if A is a Jordan matrix. This fact can be used to solve (at least in theory) systems of first-order linear differential equations. Such systems are of the form

$$\frac{dX}{dt} = AX, \quad (*)$$

where A is an $n \times n$ matrix and X is an n -dimensional vector of functions of the parameter t .

It can be shown that the columns of the matrix e^{tA} form a basis of the vector space of solutions of the system of linear differential equations (*); see Artin [7] (Chapter 4). Furthermore, for any matrix B and any invertible matrix P , if $A = PBP^{-1}$, then the system (*) is equivalent to

$$P^{-1} \frac{dX}{dt} = BP^{-1} X,$$

so if we make the change of variable $Y = P^{-1}X$, we obtain the system

$$\frac{dY}{dt} = BY. \quad (**)$$

Consequently, if B is such that the exponential e^{tB} can be easily computed, we obtain an explicit solution Y of (**), and $X = PY$ is an explicit solution of (*). This is the case when B is a Jordan form of A . In this case, it suffices to consider the Jordan blocks of B . Then we have

$$J_r(\lambda) = \lambda I_r + \begin{pmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & 0 & \ddots & 1 \\ 0 & 0 & 0 & \cdots & 0 \end{pmatrix} = \lambda I_r + N,$$

and the powers N^k are easily computed.

For example, if

$$B = \begin{pmatrix} 3 & 1 & 0 \\ 0 & 3 & 1 \\ 0 & 0 & 3 \end{pmatrix} = 3I_3 + \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}$$

we obtain

$$tB = t \begin{pmatrix} 3 & 1 & 0 \\ 0 & 3 & 1 \\ 0 & 0 & 3 \end{pmatrix} = 3tI_3 + \begin{pmatrix} 0 & t & 0 \\ 0 & 0 & t \\ 0 & 0 & 0 \end{pmatrix}$$

and so

$$e^{tB} = \begin{pmatrix} e^{3t} & 0 & 0 \\ 0 & e^{3t} & 0 \\ 0 & 0 & e^{3t} \end{pmatrix} \begin{pmatrix} 1 & t & (1/2)t^2 \\ 0 & 1 & t \\ 0 & 0 & 1 \end{pmatrix} = \begin{pmatrix} e^{3t} & te^{3t} & (1/2)t^2e^{3t} \\ 0 & e^{3t} & te^{3t} \\ 0 & 0 & e^{3t} \end{pmatrix}.$$

The columns of e^{tB} form a basis of the space of solutions of the system of linear differential equations

$$\begin{aligned} \frac{dY_1}{dt} &= 3Y_1 + Y_2 \\ \frac{dY_2}{dt} &= 3Y_2 + Y_3 \\ \frac{dY_3}{dt} &= 3Y_3, \end{aligned}$$

in matrix form,

$$\begin{pmatrix} \frac{dY_1}{dt} \\ \frac{dY_2}{dt} \\ \frac{dY_3}{dt} \end{pmatrix} = \begin{pmatrix} 3 & 1 & 0 \\ 0 & 3 & 1 \\ 0 & 0 & 3 \end{pmatrix} \begin{pmatrix} Y_1 \\ Y_2 \\ Y_3 \end{pmatrix}.$$

Explicitly, the general solution of the above system is

$$\begin{pmatrix} Y_1 \\ Y_2 \\ Y_3 \end{pmatrix} = c_1 \begin{pmatrix} e^{3t} \\ 0 \\ 0 \end{pmatrix} + c_2 \begin{pmatrix} te^{3t} \\ e^{3t} \\ 0 \end{pmatrix} + c_3 \begin{pmatrix} (1/2)t^2e^{3t} \\ te^{3t} \\ e^{3t} \end{pmatrix},$$

with $c_1, c_2, c_3 \in \mathbb{R}$. Solving systems of first-order linear differential equations is discussed in Artin [7] and more extensively in Hirsh and Smale [93].

31.7 Summary

The main concepts and results of this chapter are listed below:

- Ideals, principal ideals, greatest common divisors.
- Monic polynomial, irreducible polynomial, relatively prime polynomials.
- Annihilator of a linear map.
- Minimal polynomial of a linear map.

- Invariant subspace.
- f -conductor of u into W ; conductor of u into W .
- Diagonalizable linear maps.
- Commuting families of linear maps.
- Primary decomposition.
- Generalized eigenvectors.
- Nilpotent linear map.
- Normal form of a nilpotent linear map.
- Jordan decomposition.
- Jordan block.
- Jordan matrix.
- Jordan normal form.
- Systems of first-order linear differential equations.

31.8 Problems

Problem 31.1. Given a linear map $f: E \rightarrow E$, prove that the set $\text{Ann}(f)$ of polynomials that annihilate f is an ideal.

Problem 31.2. Provide the details of Proposition 31.3.

Problem 31.3. Prove that the f -conductor $S_f(u, W)$ is an ideal in $K[X]$ (Proposition 31.4).

Problem 31.4. Prove that the polynomials g_1, \dots, g_k used in the proof of Theorem 31.10 are relatively prime.

Problem 31.5. Find the minimal polynomial of the matrix

$$A = \begin{pmatrix} 6 & -3 & -2 \\ 4 & -1 & -2 \\ 10 & -5 & -3 \end{pmatrix}.$$

Problem 31.6. Find the Jordan decomposition of the matrix

$$A = \begin{pmatrix} 3 & 1 & -1 \\ 2 & 2 & -1 \\ 2 & 2 & 0 \end{pmatrix}.$$

Problem 31.7. Let $f: E \rightarrow E$ be a linear map on a finite-dimensional vector space. Prove that if f has rank 1, then either f is diagonalizable or f is nilpotent but not both.

Problem 31.8. Find the Jordan form of the matrix

$$A = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 3 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

Problem 31.9. Let N be a 3×3 nilpotent matrix over \mathbb{C} . Prove that the matrix $A = I + (1/2)N - (1/8)N^2$ satisfies the equation

$$A^2 = I + N.$$

In other words, A is a square root of $I + N$.

Generalize the above fact to any $n \times n$ nilpotent matrix N over \mathbb{C} using the binomial series for $(1+t)^{1/2}$.

Problem 31.10. Let K be an algebraically closed field (for example, $K = \mathbb{C}$). Prove that every 4×4 matrix is similar to a Jordan matrix of the following form:

$$\begin{array}{c} \begin{pmatrix} \lambda_1 & 0 & 0 & 0 \\ 0 & \lambda_2 & 0 & 0 \\ 0 & 0 & \lambda_3 & 0 \\ 0 & 0 & 0 & \lambda_4 \end{pmatrix}, \quad \begin{pmatrix} \lambda & 1 & 0 & 0 \\ 0 & \lambda & 0 & 0 \\ 0 & 0 & \lambda_3 & 0 \\ 0 & 0 & 0 & \lambda_4 \end{pmatrix}, \quad \begin{pmatrix} \lambda & 1 & 0 & 0 \\ 0 & \lambda & 1 & 0 \\ 0 & 0 & \lambda & 0 \\ 0 & 0 & 0 & \lambda_4 \end{pmatrix}, \\ \begin{pmatrix} \lambda & 1 & 0 & 0 \\ 0 & \lambda & 0 & 0 \\ 0 & 0 & \mu & 1 \\ 0 & 0 & 0 & \mu \end{pmatrix}, \quad \begin{pmatrix} \lambda & 1 & 0 & 0 \\ 0 & \lambda & 1 & 0 \\ 0 & 0 & \lambda & 1 \\ 0 & 0 & 0 & \lambda \end{pmatrix}. \end{array}$$

Problem 31.11. In this problem the field K is of characteristic 0. Consider an $(r \times r)$ Jordan block

$$J_r(\lambda) = \begin{pmatrix} \lambda & 1 & 0 & \cdots & 0 \\ 0 & \lambda & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & 0 & \ddots & 1 \\ 0 & 0 & 0 & \cdots & \lambda \end{pmatrix}.$$

Prove that for any polynomial $f(X)$, we have

$$f(J_r(\lambda)) = \begin{pmatrix} f(\lambda) & f_1(\lambda) & f_2(\lambda) & \cdots & f_{r-1}(\lambda) \\ 0 & f(\lambda) & f_1(\lambda) & \cdots & f_{r-2}(\lambda) \\ \vdots & \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & 0 & \ddots & f_1(\lambda) \\ 0 & 0 & 0 & \cdots & f(\lambda) \end{pmatrix},$$

where

$$f_k(X) = \frac{f^{(k)}(X)}{k!},$$

and $f^{(k)}(X)$ is the k th derivative of $f(X)$.

UFD's, Noetherian Rings, Hilbert's Basis Theorem

32.1 Unique Factorization Domains (Factorial Rings)

We saw in Section 30.5 that if K is a field, then every nonnull polynomial in $K[X]$ can be factored as a product of irreducible factors, and that such a factorization is essentially unique. The same property holds for the ring $K[X_1, \dots, X_n]$ where $n \geq 2$, but a different proof is needed.

The reason why unique factorization holds for $K[X_1, \dots, X_n]$ is that if A is an integral domain for which unique factorization holds in some suitable sense, then the property of unique factorization lifts to the polynomial ring $A[X]$. Such rings are called factorial rings, or unique factorization domains. The first step is to define the notion of irreducible element in an integral domain, and then to define a factorial ring. It will turn out that in a factorial ring, any nonnull element a is irreducible (or prime) iff the principal ideal (a) is a prime ideal.

Recall that given a ring A , a *unit* is any invertible element (w.r.t. multiplication). The set of units of A is denoted by A^* . It is a multiplicative subgroup of A , with identity 1. Also, given $a, b \in A$, recall that a divides b if $b = ac$ for some $c \in A$; equivalently, a divides b iff $(b) \subseteq (a)$. Any nonzero $a \in A$ is divisible by any unit u , since $a = u(u^{-1}a)$. The relation “ a divides b ,” often denoted by $a \mid b$, is reflexive and transitive, and thus, a preorder on $A - \{0\}$.

Definition 32.1. Let A be an integral domain. Some element $a \in A$ is *irreducible* if $a \neq 0$, $a \notin A^*$ (a is not a unit), and whenever $a = bc$, then either b or c is a unit (where $b, c \in A$). Equivalently, $a \in A$ is *reducible* if $a = 0$, or $a \in A^*$ (a is a unit), or $a = bc$ where $b, c \notin A^*$ (a, b are both noninvertible) and $b, c \neq 0$.

Observe that if $a \in A$ is irreducible and $u \in A$ is a unit, then ua is also irreducible. Generally, if $a \in A$, $a \neq 0$, and u is a unit, then a and ua are said to be *associated*. This is the equivalence relation on nonnull elements of A induced by the divisibility preorder.

The following simple proposition gives a sufficient condition for an element $a \in A$ to be irreducible.

Proposition 32.1. *Let A be an integral domain. For any $a \in A$ with $a \neq 0$, if the principal ideal (a) is a prime ideal, then a is irreducible.*

Proof. If (a) is prime, then $(a) \neq A$ and a is not a unit. Assume that $a = bc$. Then, $bc \in (a)$, and since (a) is prime, either $b \in (a)$ or $c \in (a)$. Consider the case where $b \in (a)$, the other case being similar. Then, $b = ax$ for some $x \in A$. As a consequence,

$$a = bc = axc,$$

and since A is an integral domain and $a \neq 0$, we get

$$1 = xc,$$

which proves that $c = x^{-1}$ is a unit. \square

It should be noted that the converse of Proposition 32.1 is generally false. However, it holds for factorial rings, defined next.

Definition 32.2. A *factorial ring* or *unique factorization domain (UFD)* (or *unique factorization ring*) is an integral domain A such that the following two properties hold:

- (1) For every nonnull $a \in A$, if $a \notin A^*$ (a is not a unit), then a can be factored as a product

$$a = a_1 \cdots a_m$$

where each $a_i \in A$ is irreducible ($m \geq 1$).

- (2) For every nonnull $a \in A$, if $a \notin A^*$ (a is not a unit) and if

$$a = a_1 \cdots a_m = b_1 \cdots b_n$$

where $a_i \in A$ and $b_j \in A$ are irreducible, then $m = n$ and there is a permutation σ of $\{1, \dots, m\}$ and some units $u_1, \dots, u_m \in A^*$ such that $a_i = u_i b_{\sigma(i)}$ for all i , $1 \leq i \leq m$.

Example 32.1. The ring \mathbb{Z} of integers is a typical example of a UFD. Given a field K , the polynomial ring $K[X]$ is a UFD. More generally, we will show later that every PID is a UFD (see Theorem 32.12). Thus, in particular, $\mathbb{Z}[X]$ is a UFD. However, we leave as an exercise to prove that the ideal $(2X, X^2)$ generated by $2X$ and X^2 is not principal, and thus, $\mathbb{Z}[X]$ is not a PID.

First, we prove that condition (2) in Definition 32.2 is equivalent to the usual “Euclidean” condition.

There are integral domains that are not UFD's. For example, the subring $\mathbb{Z}[\sqrt{-5}]$ of \mathbb{C} consisting of the complex numbers of the form $a + bi\sqrt{5}$ where $a, b \in \mathbb{Z}$ is not a UFD. Indeed, we have

$$9 = 3 \cdot 3 = (2 + i\sqrt{5})(2 - i\sqrt{5}),$$

and it can be shown that 3 , $2 + i\sqrt{5}$, and $2 - i\sqrt{5}$ are irreducible, and that the units are ± 1 . The uniqueness condition (2) fails and $\mathbb{Z}[\sqrt{-5}]$ is not a UFD.

Remark: For $d \in \mathbb{Z}$ with $d < 0$, it is known that the ring of integers of $\mathbb{Q}(\sqrt{d})$ is a UFD iff d is one of the nine primes, $d = -1, -2, -3, -7, -11, -19, -43, -67$ and -163 . This is a hard theorem that was conjectured by Gauss but not proved until 1966, independently by Stark and Baker. Heegner had published a proof of this result in 1952 but there was some doubt about its validity. After finding his proof, Stark reexamined Heegner's proof and concluded that it was essentially correct after all. In sharp contrast, when d is a positive integer, the problem of determining which of the rings of integers of $\mathbb{Q}(\sqrt{d})$ are UFD's, is still open. It can also be shown that if $d < 0$, then the ring $\mathbb{Z}[\sqrt{d}]$ is a UFD iff $d = -1$ or $d = -2$. If $d \equiv 1 \pmod{4}$, then $\mathbb{Z}[\sqrt{d}]$ is never a UFD. For more details about these remarkable results, see Stark [164] (Chapter 8).

Proposition 32.2. *Let A be an integral domain satisfying condition (1) in Definition 32.2. Then, condition (2) in Definition 32.2 is equivalent to the following condition:*

(2') *If $a \in A$ is irreducible and a divides the product bc , where $b, c \in A$ and $b, c \neq 0$, then either a divides b or a divides c .*

Proof. First, assume that (2) holds. Let $bc = ad$, where $d \in A$, $d \neq 0$. If b is a unit, then

$$c = adb^{-1},$$

and c is divisible by a . A similar argument applies to c . Thus, we may assume that b and c are not units. In view of (1), we can write

$$b = p_1 \cdots p_m \quad \text{and} \quad c = p_{m+1} \cdots q_{m+n},$$

where $p_i \in A$ is irreducible. Since $bc = ad$, a is irreducible, and b, c are not units, d cannot be a unit. In view of (1), we can write

$$d = q_1 \cdots q_r,$$

where $q_i \in A$ is irreducible. Thus,

$$p_1 \cdots p_m p_{m+1} \cdots p_{m+n} = a q_1 \cdots q_r,$$

where all the factors involved are irreducible. By (2), we must have

$$a = u_{i_0} p_{i_0}$$

for some unit $u_{i_0} \in A$ and some index i_0 , $1 \leq i_0 \leq m+n$. As a consequence, if $1 \leq i_0 \leq m$, then a divides b , and if $m+1 \leq i_0 \leq m+n$, then a divides c . This proves that (2') holds.

Let us now assume that (2') holds. Assume that

$$a = a_1 \cdots a_m = b_1 \cdots b_n,$$

where $a_i \in A$ and $b_j \in A$ are irreducible. Without loss of generality, we may assume that $m \leq n$. We proceed by induction on m . If $m = 1$,

$$a_1 = b_1 \cdots b_n,$$

and since a_1 is irreducible, $u = b_1 \cdots b_{i-1} b_{i+1} b_n$ must be a unit for some i , $1 \leq i \leq n$. Thus, (2) holds with $n = 1$ and $a_1 = b_i u$. Assume that $m > 1$ and that the induction hypothesis holds for $m - 1$. Since

$$a_1 a_2 \cdots a_m = b_1 \cdots b_n,$$

a_1 divides $b_1 \cdots b_n$, and in view of (2'), a_1 divides some b_j . Since a_1 and b_j are irreducible, we must have $b_j = u_j a_1$, where $u_j \in A$ is a unit. Since A is an integral domain,

$$a_1 a_2 \cdots a_m = b_1 \cdots b_{j-1} u_j a_1 b_{j+1} \cdots b_n$$

implies that

$$a_2 \cdots a_m = (u_j b_1) \cdots b_{j-1} b_{j+1} \cdots b_n,$$

and by the induction hypothesis, $m - 1 = n - 1$ and $a_i = v_i b_{\tau(i)}$ for some units $v_i \in A$ and some bijection τ between $\{2, \dots, m\}$ and $\{1, \dots, j-1, j+1, \dots, m\}$. However, the bijection τ extends to a permutation σ of $\{1, \dots, m\}$ by letting $\sigma(1) = j$, and the result holds by letting $v_1 = u_j^{-1}$. \square

As a corollary of Proposition 32.2. we get the converse of Proposition 32.1.

Proposition 32.3. *Let A be a factorial ring. For any $a \in A$ with $a \neq 0$, the principal ideal (a) is a prime ideal iff a is irreducible.*

Proof. In view of Proposition 32.1, we just have to prove that if $a \in A$ is irreducible, then the principal ideal (a) is a prime ideal. Indeed, if $bc \in (a)$, then a divides bc , and by Proposition 32.2, property (2') implies that either a divides b or a divides c , that is, either $b \in (a)$ or $c \in (a)$, which means that (a) is prime. \square

Because Proposition 32.3 holds, in a UFD, an irreducible element is often called a *prime*.

In a UFD A , every nonzero element $a \in A$ that is not a unit can be expressed as a product $a = a_1 \cdots a_n$ of irreducible elements a_i , and by property (2), the number n of factors only depends on a , that is, it is the same for all factorizations into irreducible factors. We agree that this number is 0 for a unit.

Remark: If A is a UFD, we can state the factorization properties so that they also applies to units:

- (1) For every nonnull $a \in A$, a can be factored as a product

$$a = ua_1 \cdots a_m$$

where $u \in A^*$ (u is a unit) and each $a_i \in A$ is irreducible ($m \geq 0$).

- (2) For every nonnull $a \in A$, if

$$a = ua_1 \cdots a_m = vb_1 \cdots b_n$$

where $u, v \in A^*$ (u, v are units) and $a_i \in A$ and $b_j \in A$ are irreducible, then $m = n$, and if $m = n = 0$ then $u = v$, else if $m \geq 1$, then there is a permutation σ of $\{1, \dots, m\}$ and some units $u_1, \dots, u_m \in A^*$ such that $a_i = u_i b_{\sigma(i)}$ for all i , $1 \leq i \leq m$.

We are now ready to prove that if A is a UFD, then the polynomial ring $A[X]$ is also a UFD.

First, observe that the units of $A[X]$ are just the units of A . The fact that nonnull and nonunit polynomials in $A[X]$ factor as products of irreducible polynomials is easier to prove than uniqueness. We will show in the proof of Theorem 32.10 that we can proceed by induction on the pairs (m, n) where m is the degree of $f(X)$ and n is either 0 if the coefficient f_m of X^m in $f(X)$ is a unit of n is f_m is the product of n irreducible elements.

For the uniqueness of the factorization, by Proposition 32.2, it is enough to prove that condition (2') holds. This is a little more tricky. There are several proofs, but they all involve a pretty Lemma due to Gauss.

First, note the following trivial fact. Given a ring A , for any $a \in A$, $a \neq 0$, if a divides every coefficient of some nonnull polynomial $f(X) \in A[X]$, then a divides $f(X)$. If A is an integral domain, we get the following converse.

Proposition 32.4. *Let A be an integral domain. For any $a \in A$, $a \neq 0$, if a divides a nonnull polynomial $f(X) \in A[X]$, then a divides every coefficient of $f(X)$.*

Proof. Assume that $f(X) = ag(X)$, for some $g(X) \in A[X]$. Since $a \neq 0$ and A is an integral ring, $f(X)$ and $g(X)$ have the same degree m , and since for every i ($0 \leq i \leq m$) the coefficient of X^i in $f(X)$ is equal to the coefficient of X^i in $ag(x)$, we have $f_i = ag_i$, and whenever $f_i \neq 0$, we see that a divides f_i . \square

Lemma 32.5. *(Gauss's lemma) Let A be a UFD. For any $a \in A$, if a is irreducible and a divides the product $f(X)g(X)$ of two polynomials $f(X), g(X) \in A[X]$, then either a divides $f(X)$ or a divides $g(X)$.*

Proof. Let $f(X) = f_m X^m + \cdots + f_i X^i + \cdots + f_0$ and $g(X) = g_n X^n + \cdots + g_j X^j + \cdots + g_0$. Assume that a divides neither $f(X)$ nor $g(X)$. By the (easy) converse of Proposition 32.4, there is some i ($0 \leq i \leq m$) such that a does not divide f_i , and there is some j ($0 \leq j \leq n$)

such that a does not divide g_j . Pick i and j minimal such that a does not divide f_i and a does not divide g_j . The coefficient c_{i+j} of X^{i+j} in $f(X)g(X)$ is

$$c_{i+j} = f_0 g_{i+j} + f_1 g_{i+j-1} + \cdots + f_i g_j + \cdots + f_{i+j} g_0$$

(letting $f_h = 0$ if $h > m$ and $g_k = 0$ if $k > n$). From the choice of i and j , a cannot divide $f_i g_j$, since a being irreducible, by (2') of Proposition 32.2, a would divide f_i or g_j . However, by the choice of i and j , a divides every other nonnull term in the sum for c_{i+j} , and since a is irreducible and divides $f(X)g(X)$, by Proposition 32.4, a divides c_{i+j} , which implies that a divides $f_i g_j$, a contradiction. Thus, either a divides $f(X)$ or a divides $g(X)$. \square

As a corollary, we get the following proposition.

Proposition 32.6. *Let A be a UFD. For any $a \in A$, $a \neq 0$, if a divides the product $f(X)g(X)$ of two polynomials $f(X), g(X) \in A[X]$ and $f(X)$ is irreducible and of degree at least 1, then a divides $g(X)$.*

Proof. The Proposition is trivial if a is a unit. Otherwise, $a = a_1 \cdots a_m$ where $a_i \in A$ is irreducible. Using induction and applying Lemma 32.5, we conclude that a divides $g(X)$. \square

We now show that Lemma 32.5 also applies to the case where a is an irreducible polynomial. This requires a little excursion involving the fraction field F of A .

Remark: If A is a UFD, it is possible to prove the uniqueness condition (2) for $A[X]$ directly without using the fraction field of A , see Malliavin [119], Chapter 3.

Given an integral domain A , we can construct a field F such that every element of F is of the form a/b , where $a, b \in A$, $b \neq 0$, using essentially the method for constructing the field \mathbb{Q} of rational numbers from the ring \mathbb{Z} of integers.

Proposition 32.7. *Let A be an integral domain.*

- (1) *There is a field F and an injective ring homomorphism $i: A \rightarrow F$ such that every element of F is of the form $i(a)i(b)^{-1}$, where $a, b \in A$, $b \neq 0$.*
- (2) *For every field K and every injective ring homomorphism $h: A \rightarrow K$, there is a (unique) field homomorphism $\hat{h}: F \rightarrow K$ such that*

$$\hat{h}(i(a)i(b)^{-1}) = h(a)h(b)^{-1}$$

for all $a, b \in A$, $b \neq 0$.

- (3) *The field F in (1) is unique up to isomorphism.*

Proof. (1) Consider the binary relation \simeq on $A \times (A - \{0\})$ defined as follows:

$$(a, b) \simeq (a', b') \quad \text{iff} \quad ab' = a'b.$$

It is easily seen that \simeq is an equivalence relation. Note that the fact that A is an integral domain is used to prove transitivity. The equivalence class of (a, b) is denoted by a/b . Clearly, $(0, b) \simeq (0, 1)$ for all $b \in A$, and we denote the class of $(0, 1)$ also by 0. The equivalence class $a/1$ of $(a, 1)$ is also denoted by a . We define addition and multiplication on $A \times (A - \{0\})$ as follows:

$$\begin{aligned} (a, b) + (a', b') &= (ab' + a'b, bb'), \\ (a, b) \cdot (a', b') &= (aa', bb'). \end{aligned}$$

It is easily verified that \simeq is congruential w.r.t. $+$ and \cdot , which means that $+$ and \cdot are well-defined on equivalence classes modulo \simeq . When $a, b \neq 0$, the inverse of a/b is b/a , and it is easily verified that F is a field. The map $i: A \rightarrow F$ defined such that $i(a) = a/1$ is an injection of A into F and clearly

$$\frac{a}{b} = i(a)i(b)^{-1}.$$

(2) Given an injective ring homomorphism $h: A \rightarrow K$ into a field K ,

$$\frac{a}{b} = \frac{a'}{b'} \quad \text{iff} \quad ab' = a'b,$$

which implies that

$$h(a)h(b') = h(a')h(b),$$

and since h is injective and $b, b' \neq 0$, we get

$$h(a)h(b)^{-1} = h(a')h(b')^{-1}.$$

Thus, there is a map $\hat{h}: F \rightarrow K$ such that

$$\hat{h}(a/b) = \hat{h}(i(a)i(b)^{-1}) = h(a)h(b)^{-1}$$

for all $a, b \in A$, $b \neq 0$, and it is easily checked that \hat{h} is a field homomorphism. The map \hat{h} is clearly unique.

(3) The uniqueness of F up to isomorphism follows from (2), and is left as an exercise. \square

The field F given by Proposition 32.7 is called the *fraction field of A* , and it is denoted by $\text{Frac}(A)$.

In particular, given an integral domain A , since $A[X_1, \dots, X_n]$ is also an integral domain, we can form the fraction field of the polynomial ring $A[X_1, \dots, X_n]$, denoted by $F(X_1, \dots, X_n)$, where $F = \text{Frac}(A)$ is the fraction field of A . It is also called the field

of *rational functions* over F , although the terminology is a bit misleading, since elements of $F(X_1, \dots, X_n)$ only define functions when the denominator is nonnull.

We now have the following crucial lemma which shows that if a polynomial $f(X)$ is reducible over $F[X]$ where F is the fraction field of A , then $f(X)$ is already reducible over $A[X]$.

Lemma 32.8. *Let A be a UFD and let F be the fraction field of A . For any nonnull polynomial $f(X) \in A[X]$ of degree m , if $f(X)$ is not the product of two polynomials of degree strictly smaller than m , then $f(X)$ is irreducible in $F[X]$.*

Proof. Assume that $f(X)$ is reducible in $F[X]$ and that $f(X)$ is neither null nor a unit. Then,

$$f(X) = G(X)H(X),$$

where $G(X), H(X) \in F[X]$ are polynomials of degree $p, q \geq 1$. Let a be the product of the denominators of the coefficients of $G(X)$, and b the product of the denominators of the coefficients of $H(X)$. Then, $a, b \neq 0$, $g_1(X) = aG(X) \in A[X]$ has degree $p \geq 1$, $h_1(X) = bH(X) \in A[X]$ has degree $q \geq 1$, and

$$abf(X) = g_1(X)h_1(X).$$

Let $c = ab$. If c is a unit, then $f(X)$ is also reducible in $A[X]$. Otherwise, $c = c_1 \cdots c_n$, where $c_i \in A$ is irreducible. We now use induction on n to prove that

$$f(X) = g(X)h(X),$$

for some polynomials $g(X) \in A[X]$ of degree $p \geq 1$ and $h(X) \in A[X]$ of degree $q \geq 1$.

If $n = 1$, since $c = c_1$ is irreducible, by Lemma 32.5, either c divides $g_1(X)$ or c divides $h_1(X)$. Say that c divides $g_1(X)$, the other case being similar. Then, $g_1(X) = cg(X)$ for some $g(X) \in A[X]$ of degree $p \geq 1$, and since $A[X]$ is an integral ring, we get

$$f(X) = g(X)h_1(X),$$

showing that $f(X)$ is reducible in $A[X]$. If $n > 1$, since

$$c_1 \cdots c_n f(X) = g_1(X)h_1(X),$$

c_1 divides $g_1(X)h_1(X)$, and as above, either c_1 divides $g_1(X)$ or c divides $h_1(X)$. In either case, we get

$$c_2 \cdots c_n f(X) = g_2(X)h_2(X)$$

for some polynomials $g_2(X) \in A[X]$ of degree $p \geq 1$ and $h_2(X) \in A[X]$ of degree $q \geq 1$. By the induction hypothesis, we get

$$f(X) = g(X)h(X),$$

for some polynomials $g(X) \in A[X]$ of degree $p \geq 1$ and $h(X) \in A[X]$ of degree $q \geq 1$, showing that $f(X)$ is reducible in $A[X]$. \square

Finally, we can prove that (2') holds.

Lemma 32.9. *Let A be a UFD. Given any three nonnull polynomials $f(X), g(X), h(X) \in A[X]$, if $f(X)$ is irreducible and $f(X)$ divides the product $g(X)h(X)$, then either $f(X)$ divides $g(X)$ or $f(X)$ divides $h(X)$.*

Proof. If $f(X)$ has degree 0, then the result follows from Lemma 32.5. Thus, we may assume that the degree of $f(X)$ is $m \geq 1$. Let F be the fraction field of A . By Lemma 32.8, $f(X)$ is also irreducible in $F[X]$. Since $F[X]$ is a UFD (by Theorem 30.17), either $f(X)$ divides $g(X)$ or $f(X)$ divides $h(X)$, in $F[X]$. Assume that $f(X)$ divides $g(X)$, the other case being similar. Then,

$$g(X) = f(X)G(X),$$

for some $G(X) \in F[X]$. If a is the product the denominators of the coefficients of G , we have

$$ag(X) = q_1(X)f(X),$$

where $q_1(X) = aG(X) \in A[X]$. If a is a unit, we see that $f(X)$ divides $g(X)$. Otherwise, $a = a_1 \cdots a_n$, where $a_i \in A$ is irreducible. We prove by induction on n that

$$g(X) = q(X)f(X)$$

for some $q(X) \in A[X]$.

If $n = 1$, since $f(X)$ is irreducible and of degree $m \geq 1$ and

$$a_1g(X) = q_1(X)f(X),$$

by Lemma 32.5, a_1 divides $q_1(X)$. Thus, $q_1(X) = a_1q(X)$ where $q(X) \in A[X]$. Since $A[X]$ is an integral domain, we get

$$g(X) = q(X)f(X),$$

and $f(X)$ divides $g(X)$. If $n > 1$, from

$$a_1 \cdots a_n g(X) = q_1(X)f(X),$$

we note that a_1 divides $q_1(X)f(X)$, and as in the previous case, a_1 divides $q_1(X)$. Thus, $q_1(X) = a_1q_2(X)$ where $q_2(X) \in A[X]$, and we get

$$a_2 \cdots a_n g(X) = q_2(X)f(X).$$

By the induction hypothesis, we get

$$g(X) = q(X)f(X)$$

for some $q(X) \in A[X]$, and $f(X)$ divides $g(X)$. □

We finally obtain the fact that $A[X]$ is a UFD when A is.

Theorem 32.10. *If A is a UFD then the polynomial ring $A[X]$ is also a UFD.*

Proof. As we said earlier, the factorization property (1) is easier to prove than uniqueness. Assume that $f(X)$ has degree m and let f_m be the coefficient of X^m in $f(X)$. Either f_m is a unit or it is the product of $n \geq 1$ irreducible elements. If f_m is a unit we set $n = 0$. We proceed by induction on the pair (m, n) , using the well-founded ordering on pairs, i.e.,

$$(m, n) \leq (m', n')$$

iff either $m < m'$, or $m = m'$ and $n < n'$. If $f(X)$ is a nonnull polynomial of degree 0 which is not a unit, then $f(X) \in A$, and $f(X) = f_m = a_1 \cdots a_n$ for some irreducible $a_i \in A$, since A is a UFD. This proves the base case.

If $f(X)$ has degree $m > 0$ and $f(X)$ is reducible, then

$$f(X) = g(X)h(X),$$

where $g(X)$ and $h(X)$ have degree $p, q \leq m$ and are not units. There are two cases.

(1) f_m is a unit (so $n = 0$).

If so, since $f_m = g_p h_q$ (where g_p is the coefficient of X^p in $g(X)$ and h_q is the coefficient of X^q in $h(X)$), then g_p and h_q are both units. We claim that $p, q \geq 1$. Otherwise, $p = 0$ or $q = 0$, but then either $g(X) = g_0$ is a unit or $h(X) = h_0$ is a unit, a contradiction.

Now, since $m = p + q$ and $p, q \geq 1$, we have $p, q < m$ so $(p, 0) < (m, 0)$ and $(q, 0) < (m, 0)$, and by the induction hypothesis, both $g(X)$ and $h(X)$ can be written as products of irreducible factors, thus so can $f(X)$.

(2) f_m is not a unit, say $f_m = a_1 \cdots a_n$ where a_1, \dots, a_n are irreducible and $n \geq 1$.

- (a) If $p, q < m$, then $(p, n_1) < (m, n)$ and $(q, n_2) < (m, n)$ where n_1 is the number of irreducible factors of g_p or $n_1 = 0$ if g_p is irreducible, and similarly n_2 is the number of irreducible factors of h_q or $n_2 = 0$ if h_q is irreducible (note that $n_1, n_2 \leq n$ and it is possible that $n_1 = n$ if h_q is irreducible or $n_2 = n$ if g_p is irreducible). By the induction hypothesis, $g(X)$ and $h(X)$ can be written as products of irreducible polynomials, thus so can $f(X)$.
- (b) If $p = 0$ and $q = m$, then $g(X) = g_p$ and by hypothesis g_p is not a unit. Since $f_m = a_1 \cdots a_n = g_p h_q$ and g_p is not a unit, either h_q is not a unit in which case, by the uniqueness of the number of irreducible elements in the decomposition of f_m (since A is a UFD), h_q is the product of $n_2 < n$ irreducible elements, or $n_2 = 0$ if h_q is irreducible. Since $n \geq 1$, this implies that $(m, n_2) < (m, n)$, and by the induction hypothesis $h(X)$ can be written as products of irreducible polynomials. Since $g_p \in A$ is not a unit, it can also be written as a product of irreducible elements, thus so can $f(X)$.

The case where $p = m$ and $q = 0$ is similar to the previous case.

Property (2') follows by Lemma 32.9. By Proposition 32.2, $A[X]$ is a UFD. \square

As a corollary of Theorem 32.10 and using induction, we note that for any field K , the polynomial ring $K[X_1, \dots, X_n]$ is a UFD.

For the sake of completeness, we shall prove that every PID is a UFD. First, we review the notion of gcd and the characterization of gcd's in a PID.

Given an integral domain A , for any two elements $a, b \in A$, $a, b \neq 0$, we say that $d \in A$ ($d \neq 0$) is a *greatest common divisor (gcd)* of a and b if

- (1) d divides both a and b .
- (2) For any $h \in A$ ($h \neq 0$), if h divides both a and b , then h divides d .

We also say that a and b are *relatively prime* if 1 is a gcd of a and b .

Note that a and b are relatively prime iff every gcd of a and b is a unit. If A is a PID, then gcd's are characterized as follows.

Proposition 32.11. *Let A be a PID.*

- (1) *For any $a, b, d \in A$ ($a, b, d \neq 0$), d is a gcd of a and b iff*

$$(d) = (a, b) = (a) + (b),$$

i.e., d generates the principal ideal generated by a and b .

- (2) *(Bezout identity) Two nonnull elements $a, b \in A$ are relatively prime iff there are some $x, y \in A$ such that*

$$ax + by = 1.$$

Proof. (1) Recall that the ideal generated by a and b is the set

$$(a) + (b) = aA + bA = \{ax + by \mid x, y \in A\}.$$

First, assume that d is a gcd of a and b . If so, $a \in Ad$, $b \in Ad$, and thus, $(a) \subseteq (d)$ and $(b) \subseteq (d)$, so that

$$(a) + (b) \subseteq (d).$$

Since A is a PID, there is some $t \in A$, $t \neq 0$, such that

$$(a) + (b) = (t),$$

and thus, $(a) \subseteq (t)$ and $(b) \subseteq (t)$, which means that t divides both a and b . Since d is a gcd of a and b , t must divide d . But then,

$$(d) \subseteq (t) = (a) + (b),$$

and thus, $(d) = (a) + (b)$.

Assume now that

$$(d) = (a) + (b) = (a, b).$$

Since $(a) \subseteq (d)$ and $(b) \subseteq (d)$, d divides both a and b . Assume that t divides both a and b , so that $(a) \subseteq (t)$ and $(b) \subseteq (t)$. Then,

$$(d) = (a) + (b) \subseteq (t),$$

which means that t divides d , and d is indeed a gcd of a and b .

(2) By (1), if a and b are relatively prime, then

$$(1) = (a) + (b),$$

which yields the result. Conversely, if

$$ax + by = 1,$$

then

$$(1) = (a) + (b),$$

and 1 is a gcd of a and b . □

Given two nonnull elements $a, b \in A$, if a is an irreducible element and a does not divide b , then a and b are relatively prime. Indeed, if d is not a unit and d divides both a and b , then $a = dp$ and $b = dq$ where p must be a unit, so that

$$b = ap^{-1}q,$$

and a divides b , a contradiction.

Theorem 32.12. *Let A be ring. If A is a PID, then A is a UFD.*

Proof. First, we prove that every nonnull element that is not a unit can be factored as a product of irreducible elements. Let \mathcal{S} be the set of nontrivial principal ideals (a) such that $a \neq 0$ is not a unit and cannot be factored as a product of irreducible elements (in particular, a is not irreducible). Assume that \mathcal{S} is nonempty. We claim that every ascending chain in \mathcal{S} is finite. Otherwise, consider an infinite ascending chain

$$(a_1) \subset (a_2) \subset \cdots \subset (a_n) \subset \cdots.$$

It is immediately verified that

$$\bigcup_{n \geq 1} (a_n)$$

is an ideal in A . Since A is a PID,

$$\bigcup_{n \geq 1} (a_n) = (a)$$

for some $a \in A$. However, there must be some n such that $a \in (a_n)$, and thus,

$$(a_n) \subseteq (a) \subseteq (a_n),$$

and the chain stabilizes at (a_n) .

As a consequence, there are maximal ideals in \mathcal{S} . Let (a) be a maximal ideal in \mathcal{S} . Then, for any ideal (d) such that

$$(a) \subset (d) \quad \text{and} \quad (a) \neq (d),$$

we must have $d \notin \mathcal{S}$, since otherwise (a) would not be a maximal ideal in \mathcal{S} . Observe that a is not irreducible, since $(a) \in \mathcal{S}$, and thus,

$$a = bc$$

for some $b, c \in A$, where neither b nor c is a unit. Then,

$$(a) \subseteq (b) \quad \text{and} \quad (a) \subseteq (c).$$

If $(a) = (b)$, then $b = au$ for some $u \in A$, and then

$$a = auc,$$

so that

$$1 = uc,$$

since A is an integral domain, and thus, c is a unit, a contradiction. Thus, $(a) \neq (b)$, and similarly, $(a) \neq (c)$. But then, by a previous observation $b \notin \mathcal{S}$ and $c \notin \mathcal{S}$, and since a and b are not units, both b and c factor as products of irreducible elements and so does $a = bc$, a contradiction. This implies that $\mathcal{S} = \emptyset$, so every nonnull element that is not a unit can be factored as a product of irreducible elements.

To prove the uniqueness of factorizations, we use Proposition 32.2. Assume that a is irreducible and that a divides bc . If a does not divide b , by a previous remark, a and b are relatively prime, and by Proposition 32.11, there are some $x, y \in A$ such that

$$ax + by = 1.$$

Thus,

$$acx + bcy = c,$$

and since a divides bc , we see that a must divide c , as desired. \square

Thus, we get another justification of the fact that \mathbb{Z} is a UFD and that if K is a field, then $K[X]$ is a UFD.

It should also be noted that in a UFD, gcd's of nonnull elements always exist. Indeed, this is trivial if a or b is a unit, and otherwise, we can write

$$a = p_1 \cdots p_m \quad \text{and} \quad b = q_1 \cdots q_n$$

where $p_i, q_j \in A$ are irreducible, and the product of the common factors of a and b is a gcd of a and b (it is 1 if there are no common factors).

We conclude this section on UFD's by proving a proposition characterizing when a UFD is a PID. The proof is nontrivial and makes use of Zorn's lemma (several times).

Proposition 32.13. *Let A be a ring that is a UFD, and not a field. Then, A is a PID iff every nonzero prime ideal is maximal.*

Proof. Assume that A is a PID that is not a field. Consider any nonzero prime ideal, (p) , and pick any proper ideal \mathfrak{A} in A such that

$$(p) \subseteq \mathfrak{A}.$$

Since A is a PID, the ideal \mathfrak{A} is a principal ideal, so $\mathfrak{A} = (q)$, and since \mathfrak{A} is a proper nonzero ideal, $q \neq 0$ and q is not a unit. Since

$$(p) \subseteq (q),$$

q divides p , and we have $p = qp_1$ for some $p_1 \in A$. Now, by Proposition 32.1, since $p \neq 0$ and (p) is a prime ideal, p is irreducible. But then, since $p = qp_1$ and p is irreducible, p_1 must be a unit (since q is not a unit), which implies that

$$(p) = (q);$$

that is, (p) is a maximal ideal.

Conversely, let us assume that every nonzero prime ideal is maximal. First, we prove that every prime ideal is principal. This is obvious for (0) . If \mathfrak{A} is a nonzero prime ideal, then, by hypothesis, it is maximal. Since $\mathfrak{A} \neq (0)$, there is some nonzero element $a \in \mathfrak{A}$. Since \mathfrak{A} is maximal, a is not a unit, and since A is a UFD, there is a factorization $a = a_1 \cdots a_n$ of a into irreducible elements. Since \mathfrak{A} is prime, we have $a_i \in \mathfrak{A}$ for some i . Now, by Proposition 32.3, since a_i is irreducible, the ideal (a_i) is prime, and so, by hypothesis, (a_i) is maximal. Since $(a_i) \subseteq \mathfrak{A}$ and (a_i) is maximal, we get $\mathfrak{A} = (a_i)$.

Next, assume that A is not a PID. Define the set, \mathcal{F} , by

$$\mathcal{F} = \{\mathfrak{A} \mid \mathfrak{A} \subseteq A, \quad \mathfrak{A} \text{ is not a principal ideal}\}.$$

Since A is not a PID, the set \mathcal{F} is nonempty. Also, the reader will easily check that every chain in \mathcal{F} is bounded in \mathcal{F} . Indeed, for any chain $(\mathfrak{A}_i)_{i \in I}$ of ideals in \mathcal{F} it is not hard to verify that $\bigcup_{i \in I} \mathfrak{A}_i$ is an ideal which is not principal, so $\bigcup_{i \in I} \mathfrak{A}_i \in \mathcal{F}$. Then, by Zorn's lemma (Lemma C.1), the set \mathcal{F} has some maximal element, \mathfrak{A} . Clearly, $\mathfrak{A} \neq (0)$ is a proper ideal (since $A = (1)$), and \mathfrak{A} is not prime, since we just showed that prime ideals are principal. Then, by Theorem C.3, there is some maximal ideal, \mathfrak{M} , so that $\mathfrak{A} \subset \mathfrak{M}$. However, a maximal ideal is prime, and we have shown that a prime ideal is principal. Thus,

$$\mathfrak{A} \subseteq (p),$$

for some $p \in A$ that is not a unit. Moreover, by Proposition 32.1, the element p is irreducible. Define

$$\mathfrak{B} = \{a \in A \mid pa \in \mathfrak{A}\}.$$

Clearly, $\mathfrak{A} = p\mathfrak{B}$, $\mathfrak{B} \neq (0)$, $\mathfrak{A} \subseteq \mathfrak{B}$, and \mathfrak{B} is a proper ideal. We claim that $\mathfrak{A} \neq \mathfrak{B}$. Indeed, if $\mathfrak{A} = \mathfrak{B}$ were true, then we would have $\mathfrak{A} = p\mathfrak{B} = \mathfrak{B}$, but this is impossible since p is irreducible, A is a UFD, and $\mathfrak{B} \neq (0)$ (we get $\mathfrak{B} = p^m\mathfrak{B}$ for all m , and every element of \mathfrak{B} would be a multiple of p^m for arbitrarily large m , contradicting the fact that A is a UFD). Thus, we have $\mathfrak{A} \subset \mathfrak{B}$, and since \mathfrak{A} is a maximal element of \mathcal{F} , we must have $\mathfrak{B} \notin \mathcal{F}$. However, $\mathfrak{B} \notin \mathcal{F}$ means that \mathfrak{B} is a principal ideal, and thus, $\mathfrak{A} = p\mathfrak{B}$ is also a principal ideal, a contradiction. \square

Observe that the above proof shows that Proposition 32.13 also holds under the assumption that every prime ideal is principal.

32.2 The Chinese Remainder Theorem

In this section, which is a bit of an interlude, we prove a basic result about quotients of commutative rings by products of ideals that are pairwise relatively prime. This result has applications in number theory and in the structure theorem for finitely generated modules over a PID, which will be presented later.

Given two ideals \mathfrak{a} and \mathfrak{b} of a ring A , we define the ideal \mathfrak{ab} as the set of all finite sums of the form

$$a_1b_1 + \cdots + a_kb_k, \quad a_i \in \mathfrak{a}, b_i \in \mathfrak{b}.$$

The reader should check that \mathfrak{ab} is indeed an ideal. Observe that $\mathfrak{ab} \subseteq \mathfrak{a}$ and $\mathfrak{ab} \subseteq \mathfrak{b}$, so that

$$\mathfrak{ab} \subseteq \mathfrak{a} \cap \mathfrak{b}.$$

In general equality does not hold. However if

$$\mathfrak{a} + \mathfrak{b} = A,$$

then we have

$$\mathfrak{ab} = \mathfrak{a} \cap \mathfrak{b}.$$

This is because there is some $a \in \mathfrak{a}$ and some $b \in \mathfrak{b}$ such that

$$a + b = 1,$$

so for every $x \in \mathfrak{a} \cap \mathfrak{b}$, we have

$$x = xa + xb,$$

which shows that $x \in \mathfrak{ab}$. Ideals \mathfrak{a} and \mathfrak{b} of A that satisfy the condition $\mathfrak{a} + \mathfrak{b} = A$ are sometimes said to be *comaximal*.

We define the homomorphism $\varphi: A \rightarrow A/\mathfrak{a} \times A/\mathfrak{b}$ by

$$\varphi(x) = (\bar{x}_{\mathfrak{a}}, \bar{x}_{\mathfrak{b}}),$$

where $\bar{x}_{\mathfrak{a}}$ is the equivalence class of x modulo \mathfrak{a} (resp. $\bar{x}_{\mathfrak{b}}$ is the equivalence class of x modulo \mathfrak{b}). Recall that the ideal \mathfrak{a} defines the equivalence relation $\equiv_{\mathfrak{a}}$ on A given by

$$x \equiv_{\mathfrak{a}} y \quad \text{iff} \quad x - y \in \mathfrak{a},$$

and that A/\mathfrak{a} is the quotient ring of equivalence classes $\bar{x}_{\mathfrak{a}}$, where $x \in A$, and similarly for A/\mathfrak{b} . Sometimes, we also write $x \equiv y \pmod{\mathfrak{a}}$ for $x \equiv_{\mathfrak{a}} y$.

Clearly, the kernel of the homomorphism φ is $\mathfrak{a} \cap \mathfrak{b} = \mathfrak{ab}$. If we assume that $\mathfrak{a} + \mathfrak{b} = A$, then $\text{Ker}(\varphi) = \mathfrak{a} \cap \mathfrak{b} = \mathfrak{ab}$, and because φ has a constant value on the equivalence classes modulo \mathfrak{ab} , the map φ induces a quotient homomorphism

$$\theta: A/\mathfrak{ab} \rightarrow A/\mathfrak{a} \times A/\mathfrak{b}.$$

Because $\text{Ker}(\varphi) = \mathfrak{ab}$, the homomorphism θ is injective. The Chinese Remainder Theorem says that θ is an isomorphism.

Theorem 32.14. *Given a commutative ring A , let \mathfrak{a} and \mathfrak{b} be any two ideals of A such that $\mathfrak{a} + \mathfrak{b} = A$. Then, the homomorphism $\theta: A/\mathfrak{ab} \rightarrow A/\mathfrak{a} \times A/\mathfrak{b}$ is an isomorphism.*

Proof. We already showed that θ is injective, so we need to prove that θ is surjective. We need to prove that for any $y, z \in A$, there is some $x \in A$ such that

$$\begin{aligned} x &\equiv y \pmod{\mathfrak{a}} \\ x &\equiv z \pmod{\mathfrak{b}}. \end{aligned}$$

Since $\mathfrak{a} + \mathfrak{b} = A$, there exist some $a \in \mathfrak{a}$ and some $b \in \mathfrak{b}$ such that

$$a + b = 1.$$

If we let

$$x = az + by,$$

then we have

$$x \equiv_{\mathfrak{a}} by \equiv_{\mathfrak{a}} (1 - a)y \equiv_{\mathfrak{a}} y - ay \equiv_{\mathfrak{a}} y,$$

and similarly

$$x \equiv_{\mathfrak{b}} az \equiv_{\mathfrak{b}} (1 - b)z \equiv_{\mathfrak{b}} z - bz \equiv_{\mathfrak{b}} z,$$

which shows that $x = az + by$ works. \square

Theorem 32.14 can be generalized to any (finite) number of ideals.

Theorem 32.15. (*Chinese Remainder Theorem*) Given a commutative ring A , let $\mathfrak{a}_1, \dots, \mathfrak{a}_n$ be any $n \geq 2$ ideals of A such that $\mathfrak{a}_i + \mathfrak{a}_j = A$ for all $i \neq j$. Then, the homomorphism $\theta: A/\mathfrak{a}_1 \cdots \mathfrak{a}_n \rightarrow A/\mathfrak{a}_1 \times \cdots \times A/\mathfrak{a}_n$ is an isomorphism.

Proof. The map $\theta: A/\mathfrak{a}_1 \cap \cdots \cap \mathfrak{a}_n \rightarrow A/\mathfrak{a}_1 \times \cdots \times A/\mathfrak{a}_n$ is induced by the homomorphism $\varphi: A \rightarrow A/\mathfrak{a}_1 \times \cdots \times A/\mathfrak{a}_n$ given by

$$\varphi(x) = (\bar{x}_{\mathfrak{a}_1}, \dots, \bar{x}_{\mathfrak{a}_n}).$$

Clearly, $\text{Ker}(\varphi) = \mathfrak{a}_1 \cap \cdots \cap \mathfrak{a}_n$, so θ is well-defined and injective. We need to prove that

$$\mathfrak{a}_1 \cap \cdots \cap \mathfrak{a}_n = \mathfrak{a}_1 \cdots \mathfrak{a}_n$$

and that θ is surjective. We proceed by induction. The case $n = 2$ is Theorem 32.14. By induction, assume that

$$\mathfrak{a}_2 \cap \cdots \cap \mathfrak{a}_n = \mathfrak{a}_2 \cdots \mathfrak{a}_n.$$

We claim that

$$\mathfrak{a}_1 + \mathfrak{a}_2 \cdots \mathfrak{a}_n = A.$$

Indeed, since $\mathfrak{a}_1 + \mathfrak{a}_i = A$ for $i = 2, \dots, n$, there exist some $a_i \in \mathfrak{a}_1$ and some $b_i \in \mathfrak{a}_i$ such that

$$a_i + b_i = 1, \quad i = 2, \dots, n,$$

and by multiplying these equations, we get

$$a + b_2 \cdots b_n = 1,$$

where a is a sum of terms each containing some a_j as a factor, so $a \in \mathfrak{a}_1$ and $b_2 \cdots b_n \in \mathfrak{a}_2 \cdots \mathfrak{a}_n$, which shows that

$$\mathfrak{a}_1 + \mathfrak{a}_2 \cdots \mathfrak{a}_n = A,$$

as claimed. It follows that

$$\mathfrak{a}_1 \cap \mathfrak{a}_2 \cap \cdots \cap \mathfrak{a}_n = \mathfrak{a}_1 \cap (\mathfrak{a}_2 \cdots \mathfrak{a}_n) = \mathfrak{a}_1 \mathfrak{a}_2 \cdots \mathfrak{a}_n.$$

Let us now prove that θ is surjective by induction. The case $n = 2$ is Theorem 32.14. Let x_1, \dots, x_n be any $n \geq 3$ elements of A . First, applying Theorem 32.14 to \mathfrak{a}_1 and $\mathfrak{a}_2 \cdots \mathfrak{a}_n$, we can find $y_1 \in A$ such that

$$\begin{aligned} y_1 &\equiv 1 \pmod{\mathfrak{a}_1} \\ y_1 &\equiv 0 \pmod{\mathfrak{a}_2 \cdots \mathfrak{a}_n}. \end{aligned}$$

By the induction hypothesis, we can find $y_2, \dots, y_n \in A$ such that for all i, j with $2 \leq i, j \leq n$,

$$\begin{aligned} y_i &\equiv 1 \pmod{\mathfrak{a}_i} \\ y_i &\equiv 0 \pmod{\mathfrak{a}_j}, \quad j \neq i. \end{aligned}$$

We claim that

$$x = x_1y_1 + x_2y_2 + \cdots + x_ny_n$$

works. Indeed, using the above congruences, for $i = 2, \dots, n$, we get

$$x \equiv x_1y_1 + x_i \pmod{\mathfrak{a}_i}, \quad (*)$$

but since $\mathfrak{a}_2 \cdots \mathfrak{a}_n \subseteq \mathfrak{a}_i$ for $i = 2, \dots, n$ and $y_1 \equiv 0 \pmod{\mathfrak{a}_2 \cdots \mathfrak{a}_n}$, we have

$$x_1y_1 \equiv 0 \pmod{\mathfrak{a}_i}, \quad i = 2, \dots, n$$

and equation $(*)$ reduces to

$$x \equiv x_i \pmod{\mathfrak{a}_i}, \quad i = 2, \dots, n.$$

For $i = 1$, we get

$$x \equiv x_1 \pmod{\mathfrak{a}_1},$$

therefore

$$x \equiv x_i \pmod{\mathfrak{a}_i}, \quad i = 1, \dots, n.$$

proving surjectivity. \square

The classical version of the Chinese Remainder Theorem is the case where $A = \mathbb{Z}$ and where the ideals \mathfrak{a}_i are defined by n pairwise relatively prime integers m_1, \dots, m_n . By the Bezout identity, since m_i and m_j are relatively prime whenever $i \neq j$, there exist some $u_i, u_j \in \mathbb{Z}$ such that $u_i m_i + u_j m_j = 1$, and so $m_i \mathbb{Z} + m_j \mathbb{Z} = \mathbb{Z}$. In this case, we get an isomorphism

$$\mathbb{Z}/(m_1 \cdots m_n) \mathbb{Z} \approx \prod_{i=1}^n \mathbb{Z}/m_i \mathbb{Z}.$$

In particular, if m is an integer greater than 1 and

$$m = \prod_i p_i^{r_i}$$

is its factorization into prime factors, then

$$\mathbb{Z}/m \mathbb{Z} \approx \prod_i \mathbb{Z}/p_i^{r_i} \mathbb{Z}.$$

In the previous situation where the integers m_1, \dots, m_n are pairwise relatively prime, if we write $m = m_1 \cdots m_n$ and $m'_i = m/m_i$ for $i = 1, \dots, n$, then m_i and m'_i are relatively prime, and so m'_i has an inverse modulo m_i . If t_i is such an inverse, so that

$$m'_i t_i \equiv 1 \pmod{m_i},$$

then it is not hard to show that for any $a_1, \dots, a_n \in \mathbb{Z}$,

$$x = a_1 t_1 m'_1 + \cdots + a_n t_n m'_n$$

satisfies the congruences

$$x \equiv a_i \pmod{m_i}, \quad i = 1, \dots, n.$$

Theorem 32.15 can be used to characterize rings isomorphic to finite products of quotient rings. Such rings play a role in the structure theorem for torsion modules over a PID.

Given n rings A_1, \dots, A_n , recall that the product ring $A = A_1 \times \cdots \times A_n$ is the ring in which addition and multiplication are defined componentwise. That is,

$$\begin{aligned} (a_1, \dots, a_n) + (b_1, \dots, b_n) &= (a_1 + b_1, \dots, a_n + b_n) \\ (a_1, \dots, a_n) \cdot (b_1, \dots, b_n) &= (a_1 b_1, \dots, a_n b_n). \end{aligned}$$

The additive identity is $0_A = (0, \dots, 0)$ and the multiplicative identity is $1_A = (1, \dots, 1)$. Then, for $i = 1, \dots, n$, we can define the element $e_i \in A$ as follows:

$$e_i = (0, \dots, 0, 1, 0, \dots, 0),$$

where the 1 occurs in position i . Observe that the following properties hold for all $i, j = 1, \dots, n$:

$$\begin{aligned} e_i^2 &= e_i \\ e_i e_j &= 0, \quad i \neq j \\ e_1 + \cdots + e_n &= 1_A. \end{aligned}$$

Also, for any element $a = (a_1, \dots, a_n) \in A$, we have

$$e_i a = (0, \dots, 0, a_i, 0, \dots, 0) = pr_i(a),$$

where pr_i is the projection of A onto A_i . As a consequence

$$\text{Ker}(pr_i) = (1_A - e_i)A.$$

Definition 32.3. Given a commutative ring A , a *direct decomposition* of A is a sequence $(\mathfrak{b}_1, \dots, \mathfrak{b}_n)$ of ideals in A such that there is an isomorphism $A \approx A/\mathfrak{b}_1 \times \cdots \times A/\mathfrak{b}_n$.

The following theorem gives useful conditions characterizing direct decompositions of a ring.

Theorem 32.16. *Let A be a commutative ring and let $(\mathfrak{b}_1, \dots, \mathfrak{b}_n)$ be a sequence of ideals in A . The following conditions are equivalent:*

- (a) *The sequence $(\mathfrak{b}_1, \dots, \mathfrak{b}_n)$ is a direct decomposition of A .*

(b) There exist some elements e_1, \dots, e_n of A such that

$$\begin{aligned} e_i^2 &= e_i \\ e_i e_j &= 0, \quad i \neq j \\ e_1 + \dots + e_n &= 1_A, \end{aligned}$$

and $\mathfrak{b}_i = (1_A - e_i)A$, for $i, j = 1, \dots, n$.

(c) We have $\mathfrak{b}_i + \mathfrak{b}_j = A$ for all $i \neq j$, and $\mathfrak{b}_1 \cdots \mathfrak{b}_n = (0)$.

(d) We have $\mathfrak{b}_i + \mathfrak{b}_j = A$ for all $i \neq j$, and $\mathfrak{b}_1 \cap \dots \cap \mathfrak{b}_n = (0)$.

Proof. Assume (a). Since we have an isomorphism $A \approx A/\mathfrak{b}_1 \times \dots \times A/\mathfrak{b}_n$, we may identify A with $A/\mathfrak{b}_1 \times \dots \times A/\mathfrak{b}_n$, and \mathfrak{b}_i with $\text{Ker}(pr_i)$. Then, e_1, \dots, e_n are the elements defined just before Definition 32.3. As noted, $\mathfrak{b}_i = \text{Ker}(pr_i) = (1_A - e_i)A$. This proves (b).

Assume (b). Since $\mathfrak{b}_i = (1_A - e_i)A$ and A is a ring with unit 1_A , we have $1_A - e_i \in \mathfrak{b}_i$ for $i = 1, \dots, n$. For all $i \neq j$, we also have $e_i(1_A - e_j) = e_i - e_i e_j = e_i$, so (because \mathfrak{b}_j is an ideal), $e_i \in \mathfrak{b}_j$, and thus, $1_A = 1_A - e_i + e_i \in \mathfrak{b}_i + \mathfrak{b}_j$, which shows that $\mathfrak{b}_i + \mathfrak{b}_j = A$ for all $i \neq j$. Furthermore, for any $x_i \in A$, with $1 \leq i \leq n$, we have

$$\begin{aligned} \prod_{i=1}^n x_i (1_A - e_i) &= \left(\prod_{i=1}^n x_i \right) \prod_{i=1}^n (1_A - e_i) \\ &= \left(\prod_{i=1}^n x_i \right) (1_A - \sum_{i=1}^n e_i) \\ &= 0, \end{aligned}$$

which proves that $\mathfrak{b}_1 \cdots \mathfrak{b}_n = (0)$. Thus, (c) holds.

The equivalence of (c) and (d) follows from the proof of Theorem 32.15.

The fact that (c) implies (a) is an immediate consequence of Theorem 32.15. \square

Here is example of Theorem 32.16. Take the commutative ring of residue classes mod 30, namely

$$A := \mathbb{Z}/30\mathbb{Z} = \{\bar{i}\}_{i=0}^{29}.$$

Let

$$\begin{aligned} \mathfrak{b}_1 &= 2\mathbb{Z}/30\mathbb{Z} := \{2\bar{i}\}_{i=0}^{14} \\ \mathfrak{b}_2 &= 3\mathbb{Z}/30\mathbb{Z} := \{3\bar{i}\}_{i=0}^9 \\ \mathfrak{b}_3 &= 5\mathbb{Z}/30\mathbb{Z} := \{5\bar{i}\}_{i=0}^5. \end{aligned}$$

Each \mathfrak{b}_i is an ideal in $\mathbb{Z}/30\mathbb{Z}$. Furthermore

$$\mathbb{Z}/30\mathbb{Z} = (\mathbb{Z}/30\mathbb{Z})/(2\mathbb{Z}/30\mathbb{Z}) \times (\mathbb{Z}/30\mathbb{Z})/(3\mathbb{Z}/30\mathbb{Z}) \times (\mathbb{Z}/30\mathbb{Z})/(5\mathbb{Z}/30\mathbb{Z}),$$

where

$$e_1 = (1, 0, 0) \rightarrow \bar{15}, \quad e_2 = (0, 1, 0) \rightarrow \bar{10}, \quad e_3 = (0, 0, 1) \rightarrow \bar{6},$$

since

$$\begin{aligned} \bar{15}^2 &= \bar{15}, & \bar{10}^2 &= \bar{10}, & \bar{6}^2 &= \bar{6} \\ \bar{15}\bar{10} &= \bar{15}\bar{6} = \bar{10}\bar{6} = 0, & \bar{15} + \bar{10} + \bar{6} &= \bar{1}. \end{aligned}$$

Note that $\bar{15}$ corresponds to $\bar{1} \in (\mathbb{Z}/30\mathbb{Z})/(2\mathbb{Z}/30\mathbb{Z})$, $\bar{10}$ corresponds to $\bar{1} \in (\mathbb{Z}/30\mathbb{Z})/(3\mathbb{Z}/30\mathbb{Z})$, while $\bar{6}$ corresponds to $\bar{1} \in (\mathbb{Z}/30\mathbb{Z})/(5\mathbb{Z}/30\mathbb{Z})$.

32.3 Noetherian Rings and Hilbert's Basis Theorem

Given a (commutative) ring A (with unit element 1), an ideal $\mathfrak{A} \subseteq A$ is said to be *finitely generated* if there exists a finite set $\{a_1, \dots, a_n\}$ of elements from \mathfrak{A} so that

$$\mathfrak{A} = (a_1, \dots, a_n) = \{\lambda_1 a_1 + \dots + \lambda_n a_n \mid \lambda_i \in A, 1 \leq i \leq n\}.$$

If K is a field, it turns out that every polynomial ideal \mathfrak{A} in $K[X_1, \dots, X_m]$ is finitely generated. This fact due to Hilbert and known as Hilbert's basis theorem, has very important consequences. For example, in algebraic geometry, one is interested in the zero locus of a set of polynomial equations, i.e., the set, $V(\mathcal{P})$, of n -tuples $(\lambda_1, \dots, \lambda_n) \in K^n$ so that

$$P_i(\lambda_1, \dots, \lambda_n) = 0$$

for all polynomials $P_i(X_1, \dots, X_n)$ in some given family, $\mathcal{P} = (P_i)_{i \in I}$. However, it is clear that

$$V(\mathcal{P}) = V(\mathfrak{A}),$$

where \mathfrak{A} is the ideal generated by \mathcal{P} . Then, Hilbert's basis theorem says that $V(\mathfrak{A})$ is actually defined by a *finite* number of polynomials (any set of generators of \mathfrak{A}), even if \mathcal{P} is infinite.

The property that every ideal in a ring is finitely generated is equivalent to other natural properties, one of which is the so-called *ascending chain condition*, abbreviated *a.c.c.* Before proving Hilbert's basis theorem, we explore the equivalence of these conditions.

Definition 32.4. Let A be a commutative ring with unit 1. We say that A satisfies the *ascending chain condition*, for short, the *a.c.c.*, if for every ascending chain of ideals

$$\mathfrak{A}_1 \subseteq \mathfrak{A}_2 \subseteq \dots \subseteq \mathfrak{A}_i \subseteq \dots,$$

there is some integer $n \geq 1$ so that

$$\mathfrak{A}_i = \mathfrak{A}_n \quad \text{for all } i \geq n + 1.$$

We say that A satisfies the *maximum condition* if every nonempty collection C of ideals in A has a maximal element, i.e., there is some ideal $\mathfrak{A} \in C$ which is not contained in any other ideal in C .

Proposition 32.17. *A ring A satisfies the a.c.c if and only if it satisfies the maximum condition.*

Proof. Suppose that A does not satisfy the a.c.c. Then, there is an infinite strictly ascending sequence of ideals

$$\mathfrak{A}_1 \subset \mathfrak{A}_2 \subset \cdots \subset \mathfrak{A}_i \subset \cdots,$$

and the collection $C = \{\mathfrak{A}_i\}$ has no maximal element.

Conversely, assume that A satisfies the a.c.c. Let C be a nonempty collection of ideals. Since C is nonempty, we may pick some ideal \mathfrak{A}_1 in C . If \mathfrak{A}_1 is not maximal, then there is some ideal \mathfrak{A}_2 in C so that

$$\mathfrak{A}_1 \subset \mathfrak{A}_2.$$

Using this process, if C has no maximal element, we can define by induction an infinite strictly increasing sequence

$$\mathfrak{A}_1 \subset \mathfrak{A}_2 \subset \cdots \subset \mathfrak{A}_i \subset \cdots.$$

However, the a.c.c. implies that such a sequence cannot exist. Therefore, C has a maximal element. \square

Having shown that the a.c.c. condition is equivalent to the maximal condition, we now prove that the a.c.c. condition is equivalent to the fact that every ideal is finitely generated.

Proposition 32.18. *A ring A satisfies the a.c.c if and only if every ideal is finitely generated.*

Proof. Assume that every ideal is finitely generated. Consider an ascending sequence of ideals

$$\mathfrak{A}_1 \subseteq \mathfrak{A}_2 \subseteq \cdots \subseteq \mathfrak{A}_i \subseteq \cdots.$$

Observe that $\mathfrak{A} = \bigcup_i \mathfrak{A}_i$ is also an ideal. By hypothesis, \mathfrak{A} has a finite generating set $\{a_1, \dots, a_n\}$. By definition of \mathfrak{A} , each a_i belongs to some \mathfrak{A}_{j_i} , and since the \mathfrak{A}_i form an ascending chain, there is some m so that $a_i \in \mathfrak{A}_m$ for $i = 1, \dots, n$. But then,

$$\mathfrak{A}_i = \mathfrak{A}_m$$

for all $i \geq m + 1$, and the a.c.c. holds.

Conversely, assume that the a.c.c. holds. Let \mathfrak{A} be any ideal in A and consider the family C of subideals of \mathfrak{A} that are finitely generated. The family C is nonempty, since (0) is a subideal of \mathfrak{A} . By Proposition 32.17, the family C has some maximal element, say \mathfrak{B} . For

any $a \in \mathfrak{A}$, the ideal $\mathfrak{B} + (a)$ (where $\mathfrak{B} + (a) = \{b + \lambda a \mid b \in \mathfrak{B}, \lambda \in A\}$) is also finitely generated (since \mathfrak{B} is finitely generated), and by maximality, we have

$$\mathfrak{B} = \mathfrak{B} + (a).$$

So, we get $a \in \mathfrak{B}$ for all $a \in \mathfrak{A}$, and thus, $\mathfrak{A} = \mathfrak{B}$, and \mathfrak{A} is finitely generated. \square

Definition 32.5. A commutative ring A (with unit 1) is called *noetherian* if it satisfies the a.c.c. condition. A *noetherian domain* is a noetherian ring that is also a domain.

By Proposition 32.17 and Proposition 32.18, a noetherian ring can also be defined as a ring that either satisfies the maximal property or such that every ideal is finitely generated. The proof of Hilbert's basis theorem will make use of the following lemma:

Lemma 32.19. *Let A be a (commutative) ring. For every ideal \mathfrak{A} in $A[X]$, for every $i \geq 0$, let $L_i(\mathfrak{A})$ denote the set of elements of A consisting of 0 and of the coefficients of X^i in all the polynomials $f(X) \in \mathfrak{A}$ which are of degree i . Then, the $L_i(\mathfrak{A})$'s form an ascending chain of ideals in A . Furthermore, if \mathfrak{B} is any ideal of $A[X]$ so that $\mathfrak{A} \subseteq \mathfrak{B}$ and if $L_i(\mathfrak{A}) = L_i(\mathfrak{B})$ for all $i \geq 0$, then $\mathfrak{A} = \mathfrak{B}$.*

Proof. That $L_i(\mathfrak{A})$ is an ideal and that $L_i(\mathfrak{A}) \subseteq L_{i+1}(\mathfrak{A})$ follows from the fact that if $f(X) \in \mathfrak{A}$ and $g(X) \in \mathfrak{A}$, then $f(X) + g(X)$, $\lambda f(X)$, and $Xf(X)$ all belong to \mathfrak{A} . Now, let $g(X)$ be any polynomial in \mathfrak{B} , and assume that $g(X)$ has degree n . Since $L_n(\mathfrak{A}) = L_n(\mathfrak{B})$, there is some polynomial $f_n(X)$ in \mathfrak{A} , of degree n , so that $g(X) - f_n(X)$ is of degree at most $n - 1$. Now, since $\mathfrak{A} \subseteq \mathfrak{B}$, the polynomial $g(X) - f_n(X)$ belongs to \mathfrak{B} . Using this process, we can define by induction a sequence of polynomials $f_{n+i}(X) \in \mathfrak{A}$, so that each $f_{n+i}(X)$ is either zero or has degree $n - i$, and

$$g(X) - (f_n(X) + f_{n+1}(X) + \cdots + f_{n+i}(X))$$

is of degree at most $n - i - 1$. Note that this last polynomial must be zero when $i = n$, and thus, $g(X) \in \mathfrak{A}$. \square

We now prove Hilbert's basis theorem. The proof is substantially Hilbert's original proof. A slightly shorter proof can be given but it is not as transparent as Hilbert's proof (see the remark just after the proof of Theorem 32.20, and Zariski and Samuel [194], Chapter IV, Section 1, Theorem 1).

Theorem 32.20. (*Hilbert's basis theorem*) *If A is a noetherian ring, then $A[X]$ is also a noetherian ring.*

Proof. Let \mathfrak{A} be any ideal in $A[X]$, and denote by \mathcal{L} the set of elements of A consisting of 0 and of all the coefficients of the highest degree terms of all the polynomials in \mathfrak{A} . Observe that

$$\mathcal{L} = \bigcup_i L_i(\mathfrak{A}).$$

Thus, \mathcal{L} is an ideal in A (this can also be proved directly). Since A is noetherian, \mathcal{L} is finitely generated, and let $\{a_1, \dots, a_n\}$ be a set of generators of \mathcal{L} . Let $f_1(X), \dots, f_n(X)$ be polynomials in \mathfrak{A} having respectively a_1, \dots, a_n as highest degree term coefficients. These polynomials generate an ideal \mathfrak{B} . Let q be the maximum of the degrees of the $f_i(X)$'s. Now, pick any polynomial $g(X) \in \mathfrak{A}$ of degree $d \geq q$, and let aX^d be its term of highest degree. Since $a \in \mathcal{L}$, we have

$$a = \lambda_1 a_1 + \cdots + \lambda_n a_n,$$

for some $\lambda_i \in A$. Consider the polynomial

$$g_1(X) = \sum_{i=1}^n \lambda_i f_i(X) X^{d-d_i},$$

where d_i is the degree of $f_i(X)$. Now, $g(X) - g_1(X)$ is a polynomial in \mathfrak{A} of degree at most $d-1$. By repeating this procedure, we get a sequence of polynomials $g_i(X)$ in \mathfrak{B} , having strictly decreasing degrees, and such that the polynomial

$$g(X) - (g_1(X) + \cdots + g_i(X))$$

is of degree at most $d-i$. This polynomial must be of degree at most $q-1$ as soon as $i = d-q+1$. Thus, we proved that every polynomial in \mathfrak{A} of degree $d \geq q$ belongs to \mathfrak{B} .

It remains to take care of the polynomials in \mathfrak{A} of degree at most $q-1$. Since A is noetherian, each ideal $L_i(\mathfrak{A})$ is finitely generated, and let $\{a_{i1}, \dots, a_{in_i}\}$ be a set of generators for $L_i(\mathfrak{A})$ (for $i = 0, \dots, q-1$). Let $f_{ij}(X)$ be a polynomial in \mathfrak{A} having $a_{ij}X^i$ as its highest degree term. Given any polynomial $g(X) \in \mathfrak{A}$ of degree $d \leq q-1$, if we denote its term of highest degree by aX^d , then, as in the previous argument, we can write

$$a = \lambda_1 a_{d1} + \cdots + \lambda_{n_d} a_{dn_d},$$

and we define

$$g_1(X) = \sum_{i=1}^{n_d} \lambda_i f_{di}(X) X^{d-d_i},$$

where d_i is the degree of $f_{di}(X)$. Then, $g(X) - g_1(X)$ is a polynomial in \mathfrak{A} of degree at most $d-1$, and by repeating this procedure at most q times, we get an element of \mathfrak{A} of degree 0, and the latter is a linear combination of the f_{0i} 's. This proves that every polynomial in \mathfrak{A} of degree at most $q-1$ is a combination of the polynomials $f_{ij}(X)$, for $0 \leq i \leq q-1$ and $1 \leq j \leq n_i$. Therefore, \mathfrak{A} is generated by the $f_k(X)$'s and the $f_{ij}(X)$'s, a finite number of polynomials. \square

Remark: Only a small part of Lemma 32.19 was used in the above proof, namely, the fact that $L_i(\mathfrak{A})$ is an ideal. A shorter proof of Theorem 32.21 making full use of Lemma 32.19 can be given as follows:

Proof. (Second proof) Let $(\mathfrak{A}_i)_{i \geq 1}$ be an ascending sequence of ideals in $A[X]$. Consider the doubly indexed family $(L_i(\mathfrak{A}_j))$ of ideals in A . Since A is noetherian, by the maximal property, this family has a maximal element $L_p(\mathfrak{A}_q)$. Since the $L_i(\mathfrak{A}_j)$'s form an ascending sequence when either i or j is fixed, we have $L_i(\mathfrak{A}_j) = L_p(\mathfrak{A}_q)$ for all i and j with $i \geq p$ and $j \geq q$, and thus, $L_i(\mathfrak{A}_q) = L_i(\mathfrak{A}_j)$ for all i and j with $i \geq p$ and $j \geq q$. On the other hand, for any fixed i , the a.c.c. shows that there exists some integer $n(i)$ so that $L_i(\mathfrak{A}_j) = L_i(\mathfrak{A}_{n(i)})$ for all $j \geq n(i)$. Since $L_i(\mathfrak{A}_q) = L_i(\mathfrak{A}_j)$ when $i \geq p$ and $j \geq q$, we may take $n(i) = q$ if $i \geq p$. This shows that there is some n_0 so that $n(i) \leq n_0$ for all $i \geq 0$, and thus, we have $L_i(\mathfrak{A}_j) = L_i(\mathfrak{A}_{n(0)})$ for every i and for every $j \geq n(0)$. By Lemma 32.19, we get $\mathfrak{A}_j = \mathfrak{A}_{n(0)}$ for every $j \geq n(0)$, establishing the fact that $A[X]$ satisfies the a.c.c. \square

Using induction, we immediately obtain the following important result.

Corollary 32.21. *If A is a noetherian ring, then $A[X_1, \dots, X_n]$ is also a noetherian ring.*

Since a field K is obviously noetherian (since it has only two ideals, (0) and K), we also have:

Corollary 32.22. *If K is a field, then $K[X_1, \dots, X_n]$ is a noetherian ring.*

32.4 Futher Readings

The material of this Chapter is thoroughly covered in Lang [109], Artin [7], Mac Lane and Birkhoff [118], Bourbaki [25, 26], Malliavin [119], Zariski and Samuel [194], and Van Der Waerden [179].

Chapter 33

Tensor Algebras and Symmetric Algebras

Tensors are creatures that we would prefer did not exist but keep showing up whenever multilinearity manifests itself.

One of the goals of differential geometry is to be able to generalize “calculus on \mathbb{R}^n ” to spaces more general than \mathbb{R}^n , namely manifolds. We would like to differentiate functions $f: M \rightarrow \mathbb{R}$ defined on a manifold, optimize functions (find their minima or maxima), but also to integrate such functions, as well as compute areas and volumes of subspaces of our manifold.

The suitable notion of differentiation is the notion of tangent map, a linear notion. One of the main discoveries made at the beginning of the twentieth century by Poincaré and Élie Cartan, is that the “right” approach to integration is to integrate *differential forms*, and not functions. To integrate a function f , we integrate the form $f\omega$, where ω is a *volume form* on the manifold M . The formalism of differential forms takes care of the process of the change of variables quite automatically, and allows for a very clean statement of *Stokes’ formula*.

Differential forms can be combined using a notion of product called the wedge product, but what really gives power to the formalism of differential forms is the magical operation d of *exterior differentiation*. Given a form ω , we obtain another form $d\omega$, and remarkably, the following equation holds

$$dd\omega = 0.$$

As silly as it looks, the above equation lies at the core of the notion of cohomology, a powerful algebraic tool to understand the topology of manifolds, and more generally of topological spaces.

Élie Cartan had many of the intuitions that lead to the cohomology of differential forms, but it was George de Rham who defined it rigorously and proved some important theorems about it. It turns out that the notion of Laplacian can also be defined on differential forms using a device due to Hodge, and some important theorems can be obtained: the Hodge

decomposition theorem, and Hodge's theorem about the isomorphism between the de Rham cohomology groups and the spaces of harmonic forms.

To understand all this, one needs to learn about differential forms, which turn out to be certain kinds of skew-symmetric (also called alternating) tensors.

If one's only goal is to define differential forms, then it is possible to take some short cuts and to avoid introducing the general notion of a tensor. However, tensors that are not necessarily skew-symmetric arise naturally, such as the curvature tensor, and in the theory of vector bundles, general tensor products are needed.

Consequently, we made the (perhaps painful) decision to provide a fairly detailed exposition of tensors, starting with arbitrary tensors, and then specializing to symmetric and alternating tensors. In particular, we explain rather carefully the process of taking the dual of a tensor (of all three flavors).

We refrained from following the approach in which a tensor is defined as a multilinear map defined on a product of dual spaces, because it seems very artificial and confusing (certainly to us). This approach relies on duality results that only hold in finite dimension, and consequently unnecessarily restricts the theory of tensors to finite dimensional spaces. We also feel that it is important to begin with a coordinate-free approach. Bases can be chosen for computations, but tensor algebra should not be reduced to raising or lowering indices.

Readers who feel that they are familiar with tensors should probably skip this chapter and the next. They can come back to them "by need."

We begin by defining tensor products of vector spaces over a field and then we investigate some basic properties of these tensors, in particular the existence of bases and duality. After this we investigate special kinds of tensors, namely symmetric tensors and skew-symmetric tensors. Tensor products of modules over a commutative ring with identity will be discussed very briefly. They show up naturally when we consider the space of sections of a tensor product of vector bundles.

Given a linear map $f: E \rightarrow F$ (where E and F are two vector spaces over a field K), we know that if we have a basis $(u_i)_{i \in I}$ for E , then f is completely determined by its values $f(u_i)$ on the basis vectors. For a multilinear map $f: E^n \rightarrow F$, we don't know if there is such a nice property but it would certainly be very useful.

In many respects tensor products allow us to define multilinear maps in terms of their action on a suitable basis. The crucial idea is to *linearize*, that is, to create a new vector space $E^{\otimes n}$ such that the multilinear map $f: E^n \rightarrow F$ is turned into a *linear map* $f_\otimes: E^{\otimes n} \rightarrow F$ which is equivalent to f in a strong sense. If in addition, f is symmetric, then we can define a symmetric tensor power $\text{Sym}^n(E)$, and every symmetric multilinear map $f: E^n \rightarrow F$ is turned into a *linear map* $f_\odot: \text{Sym}^n(E) \rightarrow F$ which is equivalent to f in a strong sense. Similarly, if f is alternating, then we can define a skew-symmetric tensor power $\bigwedge^n(E)$, and every alternating multilinear map is turned into a *linear map* $f_\wedge: \bigwedge^n(E) \rightarrow F$ which is equivalent to f in a strong sense.

Tensor products can be defined in various ways, some more abstract than others. We try to stay down to earth, without excess.

Before proceeding any further, we review some facts about dual spaces and pairings. Pairings will be used to deal with dual spaces of tensors.

33.1 Linear Algebra Preliminaries: Dual Spaces and Pairings

We assume that we are dealing with vector spaces over a field K . As usual the *dual space* E^* of a vector space E is defined by $E^* = \text{Hom}(E, K)$. The dual space E^* is the vector space consisting of all linear maps $\omega: E \rightarrow K$ with values in the field K .

A problem that comes up often is to decide when a space E is isomorphic to the dual F^* of some other space F (possibly equal to E). The notion of pairing due to Pontrjagin provides a very clean criterion.

Definition 33.1. Given two vector spaces E and F over a field K , a map $\langle -, - \rangle: E \times F \rightarrow K$ is a *nondegenerate pairing* iff it is bilinear and iff $\langle u, v \rangle = 0$ for all $v \in F$ implies $u = 0$, and $\langle u, v \rangle = 0$ for all $u \in E$ implies $v = 0$. A nondegenerate pairing induces two linear maps $\varphi: E \rightarrow F^*$ and $\psi: F \rightarrow E^*$ defined such that for all for all $u \in E$ and all $v \in F$, $\varphi(u)$ is the linear form in F^* and $\psi(v)$ is the linear form in E^* given by

$$\begin{aligned}\varphi(u)(y) &= \langle u, y \rangle \quad \text{for all } y \in F \\ \psi(v)(x) &= \langle x, v \rangle \quad \text{for all } x \in E.\end{aligned}$$

Schematically, $\varphi(u) = \langle u, - \rangle$ and $\psi(v) = \langle -, v \rangle$.

Proposition 33.1. *For every nondegenerate pairing $\langle -, - \rangle: E \times F \rightarrow K$, the induced maps $\varphi: E \rightarrow F^*$ and $\psi: F \rightarrow E^*$ are linear and injective. Furthermore, if E and F are finite dimensional, then $\varphi: E \rightarrow F^*$ and $\psi: F \rightarrow E^*$ are bijective.*

Proof. The maps $\varphi: E \rightarrow F^*$ and $\psi: F \rightarrow E^*$ are linear because $u, v \mapsto \langle u, v \rangle$ is bilinear. Assume that $\varphi(u) = 0$. This means that $\varphi(u)(y) = \langle u, y \rangle = 0$ for all $y \in F$, and as our pairing is nondegenerate, we must have $u = 0$. Similarly, ψ is injective. If E and F are finite dimensional, then $\dim(E) = \dim(E^*)$ and $\dim(F) = \dim(F^*)$. However, the injectivity of φ and ψ implies that that $\dim(E) \leq \dim(F^*)$ and $\dim(F) \leq \dim(E^*)$. Consequently $\dim(E) \leq \dim(F)$ and $\dim(F) \leq \dim(E)$, so $\dim(E) = \dim(F)$. Therefore, $\dim(E) = \dim(F^*)$ and φ is bijective (and similarly $\dim(F) = \dim(E^*)$ and ψ is bijective). \square

Proposition 33.1 shows that when E and F are finite dimensional, a nondegenerate pairing induces *canonical isomorphisms* $\varphi: E \rightarrow F^*$ and $\psi: F \rightarrow E^*$; that is, isomorphisms that do not depend on the choice of bases. An important special case is the case where $E = F$ and we have an inner product (a symmetric, positive definite bilinear form) on E .

Remark: When we use the term “canonical isomorphism,” we mean that such an isomorphism is defined independently of any choice of bases. For example, if E is a finite dimensional vector space and (e_1, \dots, e_n) is any basis of E , we have the dual basis (e_1^*, \dots, e_n^*) of E^* (where, $e_i^*(e_j) = \delta_{ij}$), and thus the map $e_i \mapsto e_i^*$ is an isomorphism between E and E^* . This isomorphism is *not* canonical.

On the other hand, if $\langle -, - \rangle$ is an inner product on E , then Proposition 33.1 shows that the nondegenerate pairing $\langle -, - \rangle$ on $E \times E$ induces a canonical isomorphism between E and E^* . This isomorphism is often denoted $\flat: E \rightarrow E^*$, and we usually write u^\flat for $\flat(u)$, with $u \in E$. Schematically, $u^\flat = \langle u, - \rangle$. The inverse of \flat is denoted $\sharp: E^* \rightarrow E$, and given any linear form $\omega \in E^*$, we usually write ω^\sharp for $\sharp(\omega)$. Schematically, $\omega = \langle \omega^\sharp, - \rangle$.

Given any basis, (e_1, \dots, e_n) of E (not necessarily orthonormal), let (g_{ij}) be the $n \times n$ -matrix given by $g_{ij} = \langle e_i, e_j \rangle$ (the *Gram matrix* of the inner product). Recall that the *dual basis* (e_1^*, \dots, e_n^*) of E^* consists of the coordinate forms $e_i^* \in E^*$, which are characterized by the following properties:

$$e_i^*(e_j) = \delta_{ij}, \quad 1 \leq i, j \leq n.$$

The inverse of the Gram matrix (g_{ij}) is often denoted by (g^{ij}) (by raising the indices).

The tradition of raising and lowering indices is pervasive in the literature on tensors. It is indeed useful to have some notational convention to distinguish between vectors and linear forms (also called *one-forms* or *covectors*). The usual convention is that coordinates of vectors are written using superscripts, as in $u = \sum_{i=1}^n u^i e_i$, and coordinates of one-forms are written using subscripts, as in $\omega = \sum_{i=1}^n \omega_i e_i^*$. Actually, since vectors are indexed with subscripts, one-forms are indexed with superscripts, so e_i^* should be written as e^i .

The motivation is that summation signs can then be omitted, according to the *Einstein summation convention*. According to this convention, whenever a summation variable (such as i) appears both as a subscript and a superscript in an expression, it is assumed that it is involved in a summation. For example the sum $\sum_{i=1}^n u^i e_i$ is abbreviated as

$$u^i e_i,$$

and the sum $\sum_{i=1}^n \omega_i e^i$ is abbreviated as

$$\omega_i e^i.$$

In this text we will not use the Einstein summation convention, which we find somewhat confusing, and we will also write e_i^* instead of e^i .

The maps \flat and \sharp can be described explicitly in terms of the Gram matrix of the inner product and its inverse.

Proposition 33.2. *For any vector space E , given a basis (e_1, \dots, e_n) for E and its dual basis (e_1^*, \dots, e_n^*) for E^* , for any inner product $\langle -, - \rangle$ on E , if (g_{ij}) is its Gram matrix, with*

$g_{ij} = \langle e_i, e_j \rangle$, and (g^{ij}) is its inverse, then for every vector $u = \sum_{j=1}^n u^j e_j \in E$ and every one-form $\omega = \sum_{i=1}^n \omega_i e_i^* \in E^*$, we have

$$u^\flat = \sum_{i=1}^n \omega_i e_i^*, \quad \text{with} \quad \omega_i = \sum_{j=1}^n g_{ij} u^j,$$

and

$$\omega^\sharp = \sum_{j=1}^n (\omega^\sharp)^j e_j, \quad \text{with} \quad (\omega^\sharp)^i = \sum_{j=1}^n g^{ij} \omega_j.$$

Proof. For every $u = \sum_{j=1}^n u^j e_j$, since $u^\flat(v) = \langle u, v \rangle$ for all $v \in E$, we have

$$u^\flat(e_i) = \langle u, e_i \rangle = \left\langle \sum_{j=1}^n u^j e_j, e_i \right\rangle = \sum_{j=1}^n u^j \langle e_j, e_i \rangle = \sum_{j=1}^n g_{ij} u^j,$$

so we get

$$u^\flat = \sum_{i=1}^n \omega_i e_i^*, \quad \text{with} \quad \omega_i = \sum_{j=1}^n g_{ij} u^j.$$

If we write $\omega \in E^*$ as $\omega = \sum_{i=1}^n \omega_i e_i^*$ and $\omega^\sharp \in E$ as $\omega^\sharp = \sum_{j=1}^n (\omega^\sharp)^j e_j$, since

$$\omega_i = \omega(e_i) = \langle \omega^\sharp, e_i \rangle = \sum_{j=1}^n (\omega^\sharp)^j g_{ij}, \quad 1 \leq i \leq n,$$

we get

$$(\omega^\sharp)^i = \sum_{j=1}^n g^{ij} \omega_j,$$

where (g^{ij}) is the inverse of the matrix (g_{ij}) . □

The map \flat has the effect of lowering (flattening!) indices, and the map \sharp has the effect of raising (sharpening!) indices.

Here is an explicit example of Proposition 33.2. Let (e_1, e_2) be a basis of E such that

$$\langle e_1, e_1 \rangle = 1, \quad \langle e_1, e_2 \rangle = 2, \quad \langle e_2, e_2 \rangle = 5.$$

Then

$$g = \begin{pmatrix} 1 & 2 \\ 2 & 5 \end{pmatrix}, \quad g^{-1} = \begin{pmatrix} 5 & -2 \\ -2 & 1 \end{pmatrix}.$$

Set $u = u^1 e_1 + u^2 e_2$ and observe that

$$\begin{aligned} u^\flat(e_1) &= \langle u^1 e_1 + u^2 e_2, e_1 \rangle = \langle e_1, e_1 \rangle u^1 + \langle e_2, e_1 \rangle u^2 = g_{11} u^1 + g_{12} u^2 = u^1 + 2u^2 \\ u^\flat(e_2) &= \langle u^1 e_1 + u^2 e_2, e_2 \rangle = \langle e_1, e_2 \rangle u^1 + \langle e_2, e_2 \rangle u^2 = g_{21} u^1 + g_{22} u^2 = 2u^1 + 5u^2, \end{aligned}$$

which in turn implies that

$$u^\flat = \omega_1 e_1^* + \omega_2 e_2^* = u^\flat(e_1)e_1^* + u^\flat(e_2)e_2^* = (u^1 + 2u^2)e_1^* + (2u^1 + 5u^2)e_2^*.$$

Given $\omega = \omega_1 e_1^* + \omega_2 e_2^*$, we calculate $\omega^\sharp = (\omega^\sharp)^1 e_1 + (\omega^\sharp)^2 e_2$ from the following two linear equalities:

$$\begin{aligned} \omega_1 &= \omega(e_1) = \langle \omega^\sharp, e_1 \rangle = \langle (\omega^\sharp)^1 e_1 + (\omega^\sharp)^2 e_2, e_1 \rangle \\ &= \langle e_1, e_1 \rangle (\omega^\sharp)^1 + \langle e_2, e_1 \rangle (\omega^\sharp)^2 = (\omega^\sharp)^1 + 2(\omega^\sharp)^2 = g_{11}(\omega^\sharp)^1 + g_{12}(\omega^\sharp)^2 \\ \omega_2 &= \omega(e_2) = \langle \omega^\sharp, e_2 \rangle = \langle (\omega^\sharp)^1 e_1 + (\omega^\sharp)^2 e_2, e_2 \rangle \\ &= \langle e_1, e_2 \rangle (\omega^\sharp)^1 + \langle e_2, e_2 \rangle (\omega^\sharp)^2 = 2(\omega^\sharp)^1 + 5(\omega^\sharp)^2 = g_{21}(\omega^\sharp)^1 + g_{22}(\omega^\sharp)^2. \end{aligned}$$

These equalities are concisely written as

$$\begin{pmatrix} \omega_1 \\ \omega_2 \end{pmatrix} = \begin{pmatrix} 1 & 2 \\ 2 & 5 \end{pmatrix} \begin{pmatrix} (\omega^\sharp)^1 \\ (\omega^\sharp)^2 \end{pmatrix} = g \begin{pmatrix} (\omega^\sharp)^1 \\ (\omega^\sharp)^2 \end{pmatrix}.$$

Then

$$\begin{pmatrix} (\omega^\sharp)^1 \\ (\omega^\sharp)^2 \end{pmatrix} = g^{-1} \begin{pmatrix} \omega_1 \\ \omega_2 \end{pmatrix} = \begin{pmatrix} 5 & -2 \\ -2 & 1 \end{pmatrix} \begin{pmatrix} \omega_1 \\ \omega_2 \end{pmatrix},$$

which in turn implies

$$(\omega^\sharp)^1 = 5\omega_1 - 2\omega_2, \quad (\omega^\sharp)^2 = -2\omega_1 + \omega_2,$$

i.e.

$$\omega^\sharp = (5\omega_1 - 2\omega_2)e_1 + (-2\omega_1 + \omega_2)e_2.$$

The inner product $\langle -, - \rangle$ on E induces an inner product on E^* denoted $\langle -, - \rangle_{E^*}$, and given by

$$\langle \omega_1, \omega_2 \rangle_{E^*} = \langle \omega_1^\sharp, \omega_2^\sharp \rangle, \quad \text{for all } \omega_1, \omega_2 \in E^*.$$

Then we have

$$\langle u^\flat, v^\flat \rangle_{E^*} = \langle (u^\flat)^\sharp, (v^\flat)^\sharp \rangle = \langle u, v \rangle \quad \text{for all } u, v \in E.$$

If (e_1, \dots, e_n) is a basis of E and $g_{ij} = \langle e_i, e_j \rangle$, as

$$(e_i^*)^\sharp = \sum_{k=1}^n g^{ik} e_k,$$

an easy computation shows that

$$\langle e_i^*, e_j^* \rangle_{E^*} = \langle (e_i^*)^\sharp, (e_j^*)^\sharp \rangle = g^{ij};$$

that is, in the basis (e_1^*, \dots, e_n^*) , the inner product on E^* is represented by the matrix (g^{ij}) , the inverse of the matrix (g_{ij}) .

The inner product on a finite vector space also yields a canonical isomorphism between the space $\text{Hom}(E, E; K)$ of bilinear forms on E , and the space $\text{Hom}(E, E)$ of linear maps from E to itself. Using this isomorphism, we can define the trace of a bilinear form in an intrinsic manner. This technique is used in differential geometry, for example, to define the divergence of a differential one-form.

Proposition 33.3. *If $\langle -, - \rangle$ is an inner product on a finite vector space E (over a field, K), then for every bilinear form $f: E \times E \rightarrow K$, there is a unique linear map $f^\sharp: E \rightarrow E$ such that*

$$f(u, v) = \langle f^\sharp(u), v \rangle, \quad \text{for all } u, v \in E.$$

The map $f \mapsto f^\sharp$ is a linear isomorphism between $\text{Hom}(E, E; K)$ and $\text{Hom}(E, E)$.

Proof. For every $g \in \text{Hom}(E, E)$, the map given by

$$f(u, v) = \langle g(u), v \rangle, \quad u, v \in E,$$

is clearly bilinear. It is also clear that the above defines a linear map from $\text{Hom}(E, E)$ to $\text{Hom}(E, E; K)$. This map is injective, because if $f(u, v) = 0$ for all $u, v \in E$, as $\langle -, - \rangle$ is an inner product, we get $g(u) = 0$ for all $u \in E$. Furthermore, both spaces $\text{Hom}(E, E)$ and $\text{Hom}(E, E; K)$ have the same dimension, so our linear map is an isomorphism. \square

If (e_1, \dots, e_n) is an orthonormal basis of E , then we check immediately that the trace of a linear map g (which is independent of the choice of a basis) is given by

$$\text{tr}(g) = \sum_{i=1}^n \langle g(e_i), e_i \rangle,$$

where $n = \dim(E)$.

Definition 33.2. We define the *trace of the bilinear form f* by

$$\text{tr}(f) = \text{tr}(f^\sharp).$$

From Proposition 33.3, $\text{tr}(f)$ is given by

$$\text{tr}(f) = \sum_{i=1}^n f(e_i, e_i),$$

for any orthonormal basis (e_1, \dots, e_n) of E . We can also check directly that the above expression is independent of the choice of an orthonormal basis.

We demonstrate how to calculate $\text{tr}(f)$ where $f : \mathbb{R}^2 \times \mathbb{R}^2 \rightarrow \mathbb{R}$ with $f((x_1, y_1), (x_2, y_2)) = x_1x_2 + 2x_2y_1 + 3x_1y_2 - y_1y_2$. Under the standard basis for \mathbb{R}^2 , the bilinear form f is represented as

$$(x_1 \ y_1) \begin{pmatrix} 1 & 3 \\ 2 & -1 \end{pmatrix} \begin{pmatrix} x_2 \\ y_2 \end{pmatrix}.$$

This matrix representation shows that

$$f^\sharp = \begin{pmatrix} 1 & 3 \\ 2 & -1 \end{pmatrix}^\top = \begin{pmatrix} 1 & 2 \\ 3 & -1 \end{pmatrix},$$

and hence

$$\text{tr}(f) = \text{tr}(f^\sharp) = \text{tr} \begin{pmatrix} 1 & 2 \\ 3 & -1 \end{pmatrix} = 0.$$

We will also need the following proposition to show that various families are linearly independent.

Proposition 33.4. *Let E and F be two nontrivial vector spaces and let $(u_i)_{i \in I}$ be any family of vectors $u_i \in E$. The family $(u_i)_{i \in I}$ is linearly independent iff for every family $(v_i)_{i \in I}$ of vectors $v_i \in F$, there is some linear map $f : E \rightarrow F$ so that $f(u_i) = v_i$ for all $i \in I$.*

Proof. Left as an exercise. □

33.2 Tensors Products

First we define tensor products, and then we prove their existence and uniqueness up to isomorphism.

Definition 33.3. Let K be a given field, and let E_1, \dots, E_n be $n \geq 2$ given vector spaces. For any vector space F , a map $f : E_1 \times \dots \times E_n \rightarrow F$ is *multilinear* iff it is linear in each of its argument; that is,

$$\begin{aligned} f(u_1, \dots, u_{i_1}, v + w, u_{i+1}, \dots, u_n) &= f(u_1, \dots, u_{i_1}, v, u_{i+1}, \dots, u_n) \\ &\quad + f(u_1, \dots, u_{i_1}, w, u_{i+1}, \dots, u_n) \\ f(u_1, \dots, u_{i_1}, \lambda v, u_{i+1}, \dots, u_n) &= \lambda f(u_1, \dots, u_{i_1}, v, u_{i+1}, \dots, u_n), \end{aligned}$$

for all $u_j \in E_j$ ($j \neq i$), all $v, w \in E_i$ and all $\lambda \in K$, for $i = 1, \dots, n$.

The set of multilinear maps as above forms a vector space denoted $L(E_1, \dots, E_n; F)$ or $\text{Hom}(E_1, \dots, E_n; F)$. When $n = 1$, we have the vector space of linear maps $L(E, F)$ (also denoted $\text{Hom}(E, F)$). (To be very precise, we write $\text{Hom}_K(E_1, \dots, E_n; F)$ and $\text{Hom}_K(E, F)$.)

Definition 33.4. A *tensor product* of $n \geq 2$ vector spaces E_1, \dots, E_n is a vector space T together with a multilinear map $\varphi: E_1 \times \dots \times E_n \rightarrow T$, such that for every vector space F and for every multilinear map $f: E_1 \times \dots \times E_n \rightarrow F$, there is a unique linear map $f_{\otimes}: T \rightarrow F$ with

$$f(u_1, \dots, u_n) = f_{\otimes}(\varphi(u_1, \dots, u_n)),$$

for all $u_1 \in E_1, \dots, u_n \in E_n$, or for short

$$f = f_{\otimes} \circ \varphi.$$

Equivalently, there is a unique linear map f_{\otimes} such that the following diagram commutes.

$$\begin{array}{ccc} E_1 \times \dots \times E_n & \xrightarrow{\varphi} & T \\ & \searrow f & \downarrow f_{\otimes} \\ & & F \end{array}$$

The above property is called the *universal mapping property* of the tensor product (T, φ) .

We show that any two tensor products (T_1, φ_1) and (T_2, φ_2) for E_1, \dots, E_n , are isomorphic.

Proposition 33.5. *Given any two tensor products (T_1, φ_1) and (T_2, φ_2) for E_1, \dots, E_n , there is an isomorphism $h: T_1 \rightarrow T_2$ such that*

$$\varphi_2 = h \circ \varphi_1.$$

Proof. Focusing on (T_1, φ_1) , we have a multilinear map $\varphi_2: E_1 \times \dots \times E_n \rightarrow T_2$, and thus there is a unique linear map $(\varphi_2)_{\otimes}: T_1 \rightarrow T_2$ with

$$\varphi_2 = (\varphi_2)_{\otimes} \circ \varphi_1$$

as illustrated by the following commutative diagram.

$$\begin{array}{ccc} E_1 \times \dots \times E_n & \xrightarrow{\varphi_1} & T_1 \\ & \searrow \varphi_2 & \downarrow (\varphi_2)_{\otimes} \\ & & T_2 \end{array}$$

Similarly, focusing now on (T_2, φ_2) , we have a multilinear map $\varphi_1: E_1 \times \dots \times E_n \rightarrow T_1$, and thus there is a unique linear map $(\varphi_1)_{\otimes}: T_2 \rightarrow T_1$ with

$$\varphi_1 = (\varphi_1)_{\otimes} \circ \varphi_2$$

as illustrated by the following commutative diagram.

$$\begin{array}{ccc} E_1 \times \cdots \times E_n & \xrightarrow{\varphi_2} & T_2 \\ \varphi_1 \searrow & & \downarrow (\varphi_1)_{\otimes} \\ & & T_1 \end{array}$$

Putting these diagrams together, we obtain the commutative diagrams

$$\begin{array}{ccc} & & T_1 \\ & \nearrow \varphi_1 & \downarrow (\varphi_2)_{\otimes} \\ E_1 \times \cdots \times E_n & \xrightarrow{\varphi_2} & T_2 \\ & \searrow \varphi_1 & \downarrow (\varphi_1)_{\otimes} \\ & & T_1 \end{array}$$

and

$$\begin{array}{ccc} & & T_2 \\ & \nearrow \varphi_2 & \downarrow (\varphi_1)_{\otimes} \\ E_1 \times \cdots \times E_n & \xrightarrow{\varphi_1} & T_1 \\ & \searrow \varphi_2 & \downarrow (\varphi_2)_{\otimes} \\ & & T_2, \end{array}$$

which means that

$$\varphi_1 = (\varphi_1)_{\otimes} \circ (\varphi_2)_{\otimes} \circ \varphi_1 \quad \text{and} \quad \varphi_2 = (\varphi_2)_{\otimes} \circ (\varphi_1)_{\otimes} \circ \varphi_2.$$

On the other hand, focusing on (T_1, φ_1) , we have a multilinear map $\varphi_1: E_1 \times \cdots \times E_n \rightarrow T_1$, but the unique linear map $h: T_1 \rightarrow T_1$ with

$$\varphi_1 = h \circ \varphi_1$$

is $h = \text{id}$, as illustrated by the following commutative diagram

$$\begin{array}{ccc} E_1 \times \cdots \times E_n & \xrightarrow{\varphi_1} & T_1 \\ \varphi_1 \searrow & & \downarrow \text{id} \\ & & T_1, \end{array}$$

and since $(\varphi_1)_{\otimes} \circ (\varphi_2)_{\otimes}$ is linear as a composition of linear maps, we must have

$$(\varphi_1)_{\otimes} \circ (\varphi_2)_{\otimes} = \text{id}.$$

Similarly, we have the commutative diagram

$$\begin{array}{ccc} E_1 \times \cdots \times E_n & \xrightarrow{\varphi_2} & T_2 \\ & \searrow \varphi_2 & \downarrow \text{id} \\ & & T_2, \end{array}$$

and we must have

$$(\varphi_2)_\otimes \circ (\varphi_1)_\otimes = \text{id}.$$

This shows that $(\varphi_1)_\otimes$ and $(\varphi_2)_\otimes$ are inverse linear maps, and thus, $(\varphi_2)_\otimes: T_1 \rightarrow T_2$ is an isomorphism between T_1 and T_2 . \square

Now that we have shown that tensor products are unique up to isomorphism, we give a construction that produces them. Tensor products are obtained from free vector spaces by a quotient process, so let us begin by describing the construction of the free vector space generated by a set.

For simplicity assume that our set I is finite, say

$$I = \{\heartsuit, \diamondsuit, \spadesuit, \clubsuit\}.$$

The construction works for any field K (and in fact for any commutative ring A , in which case we obtain the free A -module generated by I). Assume that $K = \mathbb{R}$. The *free vector space generated by I* is the set of all formal linear combinations of the form

$$a\heartsuit + b\diamondsuit + c\spadesuit + d\clubsuit,$$

with $a, b, c, d \in \mathbb{R}$. It is assumed that the order of the terms does not matter. For example,

$$2\heartsuit - 5\diamondsuit + 3\spadesuit = -5\diamondsuit + 2\heartsuit + 3\spadesuit.$$

Addition and multiplication by a scalar are defined as follows:

$$\begin{aligned} (a_1\heartsuit + b_1\diamondsuit + c_1\spadesuit + d_1\clubsuit) + (a_2\heartsuit + b_2\diamondsuit + c_2\spadesuit + d_2\clubsuit) \\ = (a_1 + a_2)\heartsuit + (b_1 + b_2)\diamondsuit + (c_1 + c_2)\spadesuit + (d_1 + d_2)\clubsuit, \end{aligned}$$

and

$$\alpha \cdot (a\heartsuit + b\diamondsuit + c\spadesuit + d\clubsuit) = \alpha a\heartsuit + \alpha b\diamondsuit + \alpha c\spadesuit + \alpha d\clubsuit,$$

for all $a, b, c, d, \alpha \in \mathbb{R}$. With these operations, it is immediately verified that we obtain a vector space denoted $\mathbb{R}^{(I)}$. The set I can be viewed as embedded in $\mathbb{R}^{(I)}$ by the injection ι given by

$$\iota(\heartsuit) = 1\heartsuit, \quad \iota(\diamondsuit) = 1\diamondsuit, \quad \iota(\spadesuit) = 1\spadesuit, \quad \iota(\clubsuit) = 1\clubsuit.$$

Thus, $\mathbb{R}^{(I)}$ can be viewed as the vector space with the special basis $I = \{\heartsuit, \diamondsuit, \spadesuit, \clubsuit\}$. In our case, $\mathbb{R}^{(I)}$ is isomorphic to \mathbb{R}^4 .

The exact same construction works for any field K , and we obtain a vector space denoted by $K^{(I)}$ and an injection $\iota: I \rightarrow K^{(I)}$.

The main reason why the free vector space $K^{(I)}$ over a set I is interesting is that it satisfies a *universal mapping property*. This means that for every vector space F (over the field K), any function $h: I \rightarrow F$, where F is *considered just a set*, has a unique linear extension $\bar{h}: K^{(I)} \rightarrow F$. By extension, we mean that $\bar{h}(i) = h(i)$ for all $i \in I$, or more rigorously that $h = \bar{h} \circ \iota$.

For example, if $I = \{\heartsuit, \diamondsuit, \spadesuit, \clubsuit\}$, $K = \mathbb{R}$, and $F = \mathbb{R}^3$, the function h given by

$$h(\heartsuit) = (1, 1, 1), \quad h(\diamondsuit) = (1, 1, 0), \quad h(\spadesuit) = (1, 0, 0), \quad h(\clubsuit) = (0, 0, -1)$$

has a unique linear extension $\bar{h}: \mathbb{R}^{(I)} \rightarrow \mathbb{R}^3$ to the free vector space $\mathbb{R}^{(I)}$, given by

$$\begin{aligned} \bar{h}(a\heartsuit + b\diamondsuit + c\spadesuit + d\clubsuit) &= a\bar{h}(\heartsuit) + b\bar{h}(\diamondsuit) + c\bar{h}(\spadesuit) + d\bar{h}(\clubsuit) \\ &= ah(\heartsuit) + bh(\diamondsuit) + ch(\spadesuit) + dh(\clubsuit) \\ &= a(1, 1, 1) + b(1, 1, 0) + c(1, 0, 0) + d(0, 0, -1) \\ &= (a + b + c, a + b, a - d). \end{aligned}$$

To generalize the construction of a free vector space to infinite sets I , we observe that the formal linear combination $a\heartsuit + b\diamondsuit + c\spadesuit + d\clubsuit$ can be viewed as the function $f: I \rightarrow \mathbb{R}$ given by

$$f(\heartsuit) = a, \quad f(\diamondsuit) = b, \quad f(\spadesuit) = c, \quad f(\clubsuit) = d,$$

where $a, b, c, d \in \mathbb{R}$. More generally, we can replace \mathbb{R} by any field K . If I is finite, then the set of all such functions is a vector space under pointwise addition and pointwise scalar multiplication. If I is infinite, since addition and scalar multiplication only makes sense for finite vectors, we require that our functions $f: I \rightarrow K$ take the value 0 except for possibly finitely many arguments. We can think of such functions as an infinite sequences $(f_i)_{i \in I}$ of elements f_i of K indexed by I , with only finitely many nonzero f_i . The formalization of this construction goes as follows.

Given any set I viewed as an index set, let $K^{(I)}$ be the set of all functions $f: I \rightarrow K$ such that $f(i) \neq 0$ only for finitely many $i \in I$. As usual, denote such a function by $(f_i)_{i \in I}$; it is a family of finite support. We make $K^{(I)}$ into a vector space by defining addition and scalar multiplication by

$$\begin{aligned} (f_i) + (g_i) &= (f_i + g_i) \\ \lambda(f_i) &= (\lambda f_i). \end{aligned}$$

The family $(e_i)_{i \in I}$ is defined such that $(e_i)_j = 0$ if $j \neq i$ and $(e_i)_i = 1$. It is a basis of the vector space $K^{(I)}$, so that every $w \in K^{(I)}$ can be uniquely written as a finite linear combination of the e_i . There is also an injection $\iota: I \rightarrow K^{(I)}$ such that $\iota(i) = e_i$ for every $i \in I$. Furthermore, it is easy to show that for any vector space F , and for any function

$h: I \rightarrow F$, there is a unique linear map $\bar{h}: K^{(I)} \rightarrow F$ such that $h = \bar{h} \circ \iota$, as in the following diagram.

$$\begin{array}{ccc} I & \xrightarrow{\iota} & K^{(I)} \\ & \searrow h & \downarrow \bar{h} \\ & & F \end{array}$$

Definition 33.5. The vector space $(K^{(I)}, \iota)$ constructed as above from a set I is called the *free vector space generated by I* (or over I). The commutativity of the above diagram is called the *universal mapping property* of the free vector space $(K^{(I)}, \iota)$ over I .

Using the proof technique of Proposition 33.5, it is not hard to prove that any two vector spaces satisfying the above universal mapping property are isomorphic.

We can now return to the construction of tensor products. For simplicity consider two vector spaces E_1 and E_2 . Whatever $E_1 \otimes E_2$ and $\varphi: E_1 \times E_2 \rightarrow E_1 \otimes E_2$ are, since φ is supposed to be bilinear, we must have

$$\begin{aligned} \varphi(u_1 + u_2, v_1) &= \varphi(u_1, v_1) + \varphi(u_2, v_1) \\ \varphi(u_1, v_1 + v_2) &= \varphi(u_1, v_1) + \varphi(u_1, v_2) \\ \varphi(\lambda u_1, v_1) &= \lambda \varphi(u_1, v_1) \\ \varphi(u_1, \mu v_1) &= \mu \varphi(u_1, v_1) \end{aligned}$$

for all $u_1, u_2 \in E_1$, all $v_1, v_2 \in E_2$, and all $\lambda, \mu \in K$. Since $E_1 \otimes E_2$ must satisfy the universal mapping property of Definition 33.4, we may want to define $E_1 \otimes E_2$ as the free vector space $K^{(E_1 \times E_2)}$ generated by $I = E_1 \times E_2$ and let φ be the injection of $E_1 \times E_2$ into $K^{(E_1 \times E_2)}$. The problem is that in $K^{(E_1 \times E_2)}$, vectors such that

$$(u_1 + u_2, v_1) \quad \text{and} \quad (u_1, v_1) + (u_2, v_2)$$

are different, when they should really be the same, since φ is bilinear. Since $K^{(E_1 \times E_2)}$ is free, there are no relations among the generators and this vector space is too big for our purpose.

The remedy is simple: take the quotient of the free vector space $K^{(E_1 \times E_2)}$ by the subspace N generated by the vectors of the form

$$\begin{aligned} (u_1 + u_2, v_1) - (u_1, v_1) - (u_2, v_1) \\ (u_1, v_1 + v_2) - (u_1, v_1) - (u_1, v_2) \\ (\lambda u_1, v_1) - \lambda(u_1, v_1) \\ (u_1, \mu v_1) - \mu(u_1, v_1). \end{aligned}$$

Then, if we let $E_1 \otimes E_2$ be the quotient space $K^{(E_1 \times E_2)}/N$ and let φ be the quotient map, this forces φ to be bilinear. Checking that $(K^{(E_1 \times E_2)}/N, \varphi)$ satisfies the universal mapping property is straightforward. Here is the detailed construction.

Theorem 33.6. *Given $n \geq 2$ vector spaces E_1, \dots, E_n , a tensor product $(E_1 \otimes \cdots \otimes E_n, \varphi)$ for E_1, \dots, E_n can be constructed. Furthermore, denoting $\varphi(u_1, \dots, u_n)$ as $u_1 \otimes \cdots \otimes u_n$, the tensor product $E_1 \otimes \cdots \otimes E_n$ is generated by the vectors $u_1 \otimes \cdots \otimes u_n$, where $u_1 \in E_1, \dots, u_n \in E_n$, and for every multilinear map $f: E_1 \times \cdots \times E_n \rightarrow F$, the unique linear map $f_\otimes: E_1 \otimes \cdots \otimes E_n \rightarrow F$ such that $f = f_\otimes \circ \varphi$ is defined by*

$$f_\otimes(u_1 \otimes \cdots \otimes u_n) = f(u_1, \dots, u_n)$$

on the generators $u_1 \otimes \cdots \otimes u_n$ of $E_1 \otimes \cdots \otimes E_n$.

Proof. First we apply the construction of a free vector space to the cartesian product $I = E_1 \times \cdots \times E_n$, obtaining the free vector space $M = K^{(I)}$ on $I = E_1 \times \cdots \times E_n$. Since every basis generator $e_i \in M$ is uniquely associated with some n -tuple $i = (u_1, \dots, u_n) \in E_1 \times \cdots \times E_n$, we denote e_i by (u_1, \dots, u_n) .

Next let N be the subspace of M generated by the vectors of the following type:

$$\begin{aligned} & (u_1, \dots, u_i + v_i, \dots, u_n) - (u_1, \dots, u_i, \dots, u_n) - (u_1, \dots, v_i, \dots, u_n), \\ & (u_1, \dots, \lambda u_i, \dots, u_n) - \lambda(u_1, \dots, u_i, \dots, u_n). \end{aligned}$$

We let $E_1 \otimes \cdots \otimes E_n$ be the quotient M/N of the free vector space M by N , $\pi: M \rightarrow M/N$ be the quotient map, and set

$$\varphi = \pi \circ \iota.$$

By construction, φ is multilinear, and since π is surjective and the $\iota(i) = e_i$ generate M , the fact that each i is of the form $i = (u_1, \dots, u_n) \in E_1 \times \cdots \times E_n$ implies that $\varphi(u_1, \dots, u_n)$ generate M/N . Thus, if we denote $\varphi(u_1, \dots, u_n)$ as $u_1 \otimes \cdots \otimes u_n$, the space $E_1 \otimes \cdots \otimes E_n$ is generated by the vectors $u_1 \otimes \cdots \otimes u_n$, with $u_i \in E_i$.

It remains to show that $(E_1 \otimes \cdots \otimes E_n, \varphi)$ satisfies the universal mapping property. To this end, we begin by proving there is a map h such that $f = h \circ \varphi$. Since $M = K^{(E_1 \times \cdots \times E_n)}$ is free on $I = E_1 \times \cdots \times E_n$, there is a unique linear map $\bar{f}: K^{(E_1 \times \cdots \times E_n)} \rightarrow F$, such that

$$f = \bar{f} \circ \iota,$$

as in the diagram below.

$$\begin{array}{ccc} E_1 \times \cdots \times E_n & \xrightarrow{\iota} & K^{(E_1 \times \cdots \times E_n)} = M \\ & \searrow f & \downarrow \bar{f} \\ & & F \end{array}$$

Because f is multilinear, note that we must have $\bar{f}(w) = 0$ for every $w \in N$; for example, on the generator

$$(u_1, \dots, u_i + v_i, \dots, u_n) - (u_1, \dots, u_i, \dots, u_n) - (u_1, \dots, v_i, \dots, u_n)$$

we have

$$\begin{aligned}
& \bar{f}((u_1, \dots, u_i + v_i, \dots, u_n) - (u_1, \dots, u_i, \dots, u_n) - (u_1, \dots, v_i, \dots, u_n)) \\
&= f(u_1, \dots, u_i + v_i, \dots, u_n) - f(u_1, \dots, u_i, \dots, u_n) - f(u_1, \dots, v_i, \dots, u_n) \\
&= f(u_1, \dots, u_i, \dots, u_n) + f(u_1, \dots, v_i, \dots, u_n) - f(u_1, \dots, u_i, \dots, u_n) \\
&\quad - f(u_1, \dots, v_i, \dots, u_n) \\
&= 0.
\end{aligned}$$

But then, $\bar{f}: M \rightarrow F$ factors through M/N , which means that there is a unique linear map $h: M/N \rightarrow F$ such that $\bar{f} = h \circ \pi$ making the following diagram commute

$$\begin{array}{ccc}
M & \xrightarrow{\pi} & M/N \\
& \searrow \bar{f} & \downarrow h \\
& & F,
\end{array}$$

by defining $h([z]) = \bar{f}(z)$ for every $z \in M$, where $[z]$ denotes the equivalence class in M/N of $z \in M$. Indeed, the fact that \bar{f} vanishes on N insures that h is well defined on M/N , and it is clearly linear by definition. Since $f = \bar{f} \circ \iota$, from the equation $\bar{f} = h \circ \pi$, by composing on the right with ι , we obtain

$$f = \bar{f} \circ \iota = h \circ \pi \circ \iota = h \circ \varphi,$$

as in the following commutative diagram.

$$\begin{array}{ccccc}
& & K^{(E_1 \times \cdots \times E_n)} & & \\
& \swarrow \iota & \downarrow \bar{f} & \searrow \pi & \\
E_1 \times \cdots \times E_n & & F & & K^{(E_1 \times \cdots \times E_n)}/N \\
& \searrow f & & \swarrow h & \\
& & F & &
\end{array}$$

We now prove the uniqueness of h . For any linear map $f_\otimes: E_1 \otimes \cdots \otimes E_n \rightarrow F$ such that $f = f_\otimes \circ \varphi$, since the vectors $u_1 \otimes \cdots \otimes u_n$ generate $E_1 \otimes \cdots \otimes E_n$ and since $\varphi(u_1, \dots, u_n) = u_1 \otimes \cdots \otimes u_n$, the map f_\otimes is uniquely defined by

$$f_\otimes(u_1 \otimes \cdots \otimes u_n) = f(u_1, \dots, u_n).$$

Since $f = h \circ \varphi$, the map h is unique, and we let $f_\otimes = h$. \square

The map φ from $E_1 \times \cdots \times E_n$ to $E_1 \otimes \cdots \otimes E_n$ is often denoted by ι_\otimes , so that

$$\iota_\otimes(u_1, \dots, u_n) = u_1 \otimes \cdots \otimes u_n.$$

What is important about Theorem 33.6 is not so much the construction itself but the fact that it produces a tensor product with the universal mapping property with respect to multilinear maps. Indeed, Theorem 33.6 yields a canonical isomorphism

$$\mathrm{L}(E_1 \otimes \cdots \otimes E_n, F) \cong \mathrm{L}(E_1, \dots, E_n; F)$$

between the vector space of linear maps $\mathrm{L}(E_1 \otimes \cdots \otimes E_n, F)$, and the vector space of multilinear maps $\mathcal{L}(E_1, \dots, E_n; F)$, via the linear map $- \circ \varphi$ defined by

$$h \mapsto h \circ \varphi,$$

where $h \in \mathrm{L}(E_1 \otimes \cdots \otimes E_n, F)$. Indeed, $h \circ \varphi$ is clearly multilinear, and since by Theorem 33.6, for every multilinear map $f \in \mathcal{L}(E_1, \dots, E_n; F)$, there is a unique linear map $f_\otimes \in \mathrm{L}(E_1 \otimes \cdots \otimes E_n, F)$ such that $f = f_\otimes \circ \varphi$, the map $- \circ \varphi$ is bijective. As a matter of fact, its inverse is the map

$$f \mapsto f_\otimes.$$

We record this fact as the following proposition.

Proposition 33.7. *Given a tensor product $(E_1 \otimes \cdots \otimes E_n, \varphi)$, the linear map $h \mapsto h \circ \varphi$ is a canonical isomorphism*

$$\mathrm{L}(E_1 \otimes \cdots \otimes E_n, F) \cong \mathrm{L}(E_1, \dots, E_n; F)$$

between the vector space of linear maps $\mathrm{L}(E_1 \otimes \cdots \otimes E_n, F)$, and the vector space of multilinear maps $\mathcal{L}(E_1, \dots, E_n; F)$.

Using the “Hom” notation, the above canonical isomorphism is written

$$\mathrm{Hom}(E_1 \otimes \cdots \otimes E_n, F) \cong \mathrm{Hom}(E_1, \dots, E_n; F).$$

Remarks:

- (1) To be very precise, since the tensor product depends on the field K , we should subscript the symbol \otimes with K and write

$$E_1 \otimes_K \cdots \otimes_K E_n.$$

However, we often omit the subscript K unless confusion may arise.

- (2) For $F = K$, the base field, Proposition 33.7 yields a canonical isomorphism between the vector space $\mathrm{L}(E_1 \otimes \cdots \otimes E_n, K)$, and the vector space of multilinear forms $\mathcal{L}(E_1, \dots, E_n; K)$. However, $\mathrm{L}(E_1 \otimes \cdots \otimes E_n, K)$ is the dual space $(E_1 \otimes \cdots \otimes E_n)^*$, and thus the vector space of multilinear forms $\mathcal{L}(E_1, \dots, E_n; K)$ is canonically isomorphic to $(E_1 \otimes \cdots \otimes E_n)^*$.

Since this isomorphism is used often, we record it as the following proposition.

Proposition 33.8. *Given a tensor product $E_1 \otimes \cdots \otimes E_n$, there is a canonical isomorphism*

$$\mathcal{L}(E_1, \dots, E_n; K) \cong (E_1 \otimes \cdots \otimes E_n)^*$$

between the vector space of multilinear maps $\mathcal{L}(E_1, \dots, E_n; K)$ and the dual $(E_1 \otimes \cdots \otimes E_n)^$ of the tensor product $E_1 \otimes \cdots \otimes E_n$.*

The fact that the map $\varphi: E_1 \times \cdots \times E_n \rightarrow E_1 \otimes \cdots \otimes E_n$ is multilinear, can also be expressed as follows:

$$\begin{aligned} u_1 \otimes \cdots \otimes (v_i + w_i) \otimes \cdots \otimes u_n &= (u_1 \otimes \cdots \otimes v_i \otimes \cdots \otimes u_n) + (u_1 \otimes \cdots \otimes w_i \otimes \cdots \otimes u_n), \\ u_1 \otimes \cdots \otimes (\lambda u_i) \otimes \cdots \otimes u_n &= \lambda(u_1 \otimes \cdots \otimes u_i \otimes \cdots \otimes u_n). \end{aligned}$$

Of course, this is just what we wanted!

Definition 33.6. Tensors in $E_1 \otimes \cdots \otimes E_n$ are called *n-tensors*, and tensors of the form $u_1 \otimes \cdots \otimes u_n$, where $u_i \in E_i$ are called *simple (or decomposable) n-tensors*. Those *n-tensors* that are not simple are often called *compound n-tensors*.

Not only do tensor products act on spaces, but they also act on linear maps (they are functors).

Proposition 33.9. *Given two linear maps $f: E \rightarrow E'$ and $g: F \rightarrow F'$, there is a unique linear map*

$$f \otimes g: E \otimes F \rightarrow E' \otimes F'$$

such that

$$(f \otimes g)(u \otimes v) = f(u) \otimes g(v),$$

for all $u \in E$ and all $v \in F$.

Proof. We can define $h: E \times F \rightarrow E' \otimes F'$ by

$$h(u, v) = f(u) \otimes g(v).$$

It is immediately verified that h is bilinear, and thus it induces a unique linear map

$$f \otimes g: E \otimes F \rightarrow E' \otimes F'$$

making the following diagram commutes

$$\begin{array}{ccc} E \times F & \xrightarrow{\iota_{\otimes}} & E \otimes F \\ & \searrow h & \downarrow f \otimes g \\ & & E' \otimes F', \end{array}$$

such that $(f \otimes g)(u \otimes v) = f(u) \otimes g(v)$, for all $u \in E$ and all $v \in F$. \square

Definition 33.7. The linear map $f \otimes g: E \otimes F \rightarrow E' \otimes F'$ given by Proposition 33.9 is called the *tensor product* of $f: E \rightarrow E'$ and $g: F \rightarrow F'$.

Another way to define $f \otimes g$ proceeds as follows. Given two linear maps $f: E \rightarrow E'$ and $g: F \rightarrow F'$, the map $f \times g$ is the linear map from $E \times F$ to $E' \times F'$ given by

$$(f \times g)(u, v) = (f(u), g(v)), \quad \text{for all } u \in E \text{ and all } v \in F.$$

Then the map h in the proof of Proposition 33.9 is given by $h = \iota'_\otimes \circ (f \times g)$, and $f \otimes g$ is the unique linear map making the following diagram commute.

$$\begin{array}{ccc} E \times F & \xrightarrow{\iota_\otimes} & E \otimes F \\ f \times g \downarrow & & \downarrow f \otimes g \\ E' \times F' & \xrightarrow{\iota'_\otimes} & E' \otimes F' \end{array}$$

Remark: The notation $f \otimes g$ is potentially ambiguous, because $\text{Hom}(E, F)$ and $\text{Hom}(E', F')$ are vector spaces, so we can form the tensor product $\text{Hom}(E, F) \otimes \text{Hom}(E', F')$ which contains elements also denoted $f \otimes g$. To avoid confusion, the first kind of tensor product of linear maps defined in Proposition 33.9 (which yields a linear map in $\text{Hom}(E \otimes F, E' \otimes F')$) can be denoted by $T(f, g)$. If we denote the tensor product $E \otimes F$ by $T(E, F)$, this notation makes it clearer that T is a bifunctor. If E, E' and F, F' are finite dimensional, by picking bases it is not hard to show that the map induced by $f \otimes g \mapsto T(f, g)$ is an isomorphism

$$\text{Hom}(E, F) \otimes \text{Hom}(E', F') \cong \text{Hom}(E \otimes F, E' \otimes F').$$

Proposition 33.10. Suppose we have linear maps $f: E \rightarrow E'$, $g: F \rightarrow F'$, $f': E' \rightarrow E''$ and $g': F' \rightarrow F''$. Then the following identity holds:

$$(f' \circ f) \otimes (g' \circ g) = (f' \otimes g') \circ (f \otimes g). \quad (*)$$

Proof. We have the commutative diagram

$$\begin{array}{ccc} E \times F & \xrightarrow{\iota_\otimes} & E \otimes F \\ f \times g \downarrow & & \downarrow f \otimes g \\ E' \times F' & \xrightarrow{\iota'_\otimes} & E' \otimes F' \\ f' \times g' \downarrow & & \downarrow f' \otimes g' \\ E'' \times F'' & \xrightarrow{\iota''_\otimes} & E'' \otimes F'', \end{array}$$

and thus the commutative diagram.

$$\begin{array}{ccc} E \times F & \xrightarrow{\iota_\otimes} & E \otimes F \\ (f' \times g') \circ (f \times g) \downarrow & & \downarrow (f' \otimes g') \circ (f \otimes g) \\ E'' \times F'' & \xrightarrow{\iota''_\otimes} & E'' \otimes F'' \end{array}$$

We also have the commutative diagram.

$$\begin{array}{ccc}
 E \times F & \xrightarrow{\iota^\otimes} & E \otimes F \\
 (f' \circ f) \times (g' \circ g) \downarrow & & \downarrow (f' \circ f) \otimes (g' \circ g) \\
 E'' \times F'' & \xrightarrow{\iota''_\otimes} & E'' \otimes F''.
 \end{array}$$

Since we immediately verify that

$$(f' \circ f) \times (g' \circ g) = (f' \times g') \circ (f \times g),$$

by uniqueness of the map between $E \otimes F$ and $E'' \otimes F''$ in the above diagram, we conclude that

$$(f' \circ f) \otimes (g' \circ g) = (f' \otimes g') \circ (f \otimes g),$$

as claimed. \square

The above formula (*) yields the following useful fact.

Proposition 33.11. *If $f: E \rightarrow E'$ and $g: F \rightarrow F'$ are isomorphisms, then $f \otimes g: E \otimes F \rightarrow E' \otimes F'$ is also an isomorphism.*

Proof. If $f^{-1}: E' \rightarrow E$ is the inverse of $f: E \rightarrow E'$ and $g^{-1}: F' \rightarrow F$ is the inverse of $g: F \rightarrow F'$, then $f^{-1} \otimes g^{-1}: E' \otimes F' \rightarrow E \otimes F$ is the inverse of $f \otimes g: E \otimes F \rightarrow E' \otimes F'$, which is shown as follows:

$$\begin{aligned}
 (f \otimes g) \circ (f^{-1} \otimes g^{-1}) &= (f \circ f^{-1}) \otimes (g \circ g^{-1}) \\
 &= \text{id}_{E'} \otimes \text{id}_{F'} \\
 &= \text{id}_{E' \otimes F'},
 \end{aligned}$$

and

$$\begin{aligned}
 (f^{-1} \otimes g^{-1}) \circ (f \otimes g) &= (f^{-1} \circ f) \otimes (g^{-1} \circ g) \\
 &= \text{id}_E \otimes \text{id}_F \\
 &= \text{id}_{E \otimes F}.
 \end{aligned}$$

Therefore, $f \otimes g: E \otimes F \rightarrow E' \otimes F'$ is an isomorphism. \square

The generalization to the tensor product $f_1 \otimes \cdots \otimes f_n$ of $n \geq 3$ linear maps $f_i: E_i \rightarrow F_i$ is immediate, and left to the reader.

33.3 Bases of Tensor Products

We showed that $E_1 \otimes \cdots \otimes E_n$ is generated by the vectors of the form $u_1 \otimes \cdots \otimes u_n$. However, these vectors are not linearly independent. This situation can be fixed when considering bases.

To explain the idea of the proof, consider the case when we have two spaces E and F both of dimension 3. Given a basis (e_1, e_2, e_3) of E and a basis (f_1, f_2, f_3) of F , we would like to prove that

$$e_1 \otimes f_1, \quad e_1 \otimes f_2, \quad e_1 \otimes f_3, \quad e_2 \otimes f_1, \quad e_2 \otimes f_2, \quad e_2 \otimes f_3, \quad e_3 \otimes f_1, \quad e_3 \otimes f_2, \quad e_3 \otimes f_3$$

are linearly independent. To prove this, it suffices to show that for any vector space G , if $w_{11}, w_{12}, w_{13}, w_{21}, w_{22}, w_{23}, w_{31}, w_{32}, w_{33}$ are any vectors in G , then there is a bilinear map $h: E \times F \rightarrow G$ such that

$$h(e_i, e_j) = w_{ij}, \quad 1 \leq i, j \leq 3.$$

Because h yields a unique linear map $h_\otimes: E \otimes F \rightarrow G$ such that

$$h_\otimes(e_i \otimes e_j) = w_{ij}, \quad 1 \leq i, j \leq 3,$$

and by Proposition 33.4, the vectors

$$e_1 \otimes f_1, \quad e_1 \otimes f_2, \quad e_1 \otimes f_3, \quad e_2 \otimes f_1, \quad e_2 \otimes f_2, \quad e_2 \otimes f_3, \quad e_3 \otimes f_1, \quad e_3 \otimes f_2, \quad e_3 \otimes f_3$$

are linearly independent. This suggests understanding how a bilinear function $f: E \times F \rightarrow G$ is expressed in terms of its values $f(e_i, f_j)$ on the basis vectors (e_1, e_2, e_3) and (f_1, f_2, f_3) , and this can be done easily. Using bilinearity we obtain

$$\begin{aligned} f(u_1 e_1 + u_2 e_2 + u_3 e_3, v_1 f_1 + v_2 f_2 + v_3 f_3) &= u_1 v_1 f(e_1, f_1) + u_1 v_2 f(e_1, f_2) + u_1 v_3 f(e_1, f_3) \\ &\quad + u_2 v_1 f(e_2, f_1) + u_2 v_2 f(e_2, f_2) + u_2 v_3 f(e_2, f_3) \\ &\quad + u_3 v_1 f(e_3, f_1) + u_3 v_2 f(e_3, f_2) + u_3 v_3 f(e_3, f_3). \end{aligned}$$

Therefore, given $w_{11}, w_{12}, w_{13}, w_{21}, w_{22}, w_{23}, w_{31}, w_{32}, w_{33} \in G$, the function h given by

$$\begin{aligned} h(u_1 e_1 + u_2 e_2 + u_3 e_3, v_1 f_1 + v_2 f_2 + v_3 f_3) &= u_1 v_1 w_{11} + u_1 v_2 w_{12} + u_1 v_3 w_{13} \\ &\quad + u_2 v_1 w_{21} + u_2 v_2 w_{22} + u_2 v_3 w_{23} \\ &\quad + u_3 v_1 w_{31} + u_3 v_2 w_{32} + u_3 v_3 w_{33} \end{aligned}$$

is clearly bilinear, and by construction $h(e_i, f_j) = w_{ij}$, so it does the job.

The generalization of this argument to any number of vector spaces of any dimension (even infinite) is straightforward.

Proposition 33.12. *Given $n \geq 2$ vector spaces E_1, \dots, E_n , if $(u_i^k)_{i \in I_k}$ is a basis for E_k , $1 \leq k \leq n$, then the family of vectors*

$$(u_{i_1}^1 \otimes \cdots \otimes u_{i_n}^n)_{(i_1, \dots, i_n) \in I_1 \times \cdots \times I_n}$$

is a basis of the tensor product $E_1 \otimes \cdots \otimes E_n$.

Proof. For each k , $1 \leq k \leq n$, every $v^k \in E_k$ can be written uniquely as

$$v^k = \sum_{j \in I_k} v_j^k u_j^k,$$

for some family of scalars $(v_j^k)_{j \in I_k}$. Let F be any nontrivial vector space. We show that for every family

$$(w_{i_1, \dots, i_n})_{(i_1, \dots, i_n) \in I_1 \times \dots \times I_n},$$

of vectors in F , there is some linear map $h: E_1 \otimes \dots \otimes E_n \rightarrow F$ such that

$$h(u_{i_1}^1 \otimes \dots \otimes u_{i_n}^n) = w_{i_1, \dots, i_n}.$$

Then by Proposition 33.4, it follows that

$$(u_{i_1}^1 \otimes \dots \otimes u_{i_n}^n)_{(i_1, \dots, i_n) \in I_1 \times \dots \times I_n}$$

is linearly independent. However, since $(u_i^k)_{i \in I_k}$ is a basis for E_k , the $u_{i_1}^1 \otimes \dots \otimes u_{i_n}^n$ also generate $E_1 \otimes \dots \otimes E_n$, and thus, they form a basis of $E_1 \otimes \dots \otimes E_n$.

We define the function $f: E_1 \times \dots \times E_n \rightarrow F$ as follows: For any n nonempty finite subsets J_1, \dots, J_n such that $J_k \subseteq I_k$ for $k = 1, \dots, n$,

$$f\left(\sum_{j_1 \in J_1} v_{j_1}^1 u_{j_1}^1, \dots, \sum_{j_n \in J_n} v_{j_n}^n u_{j_n}^n\right) = \sum_{j_1 \in J_1, \dots, j_n \in J_n} v_{j_1}^1 \cdots v_{j_n}^n w_{j_1, \dots, j_n}.$$

It is immediately verified that f is multilinear. By the universal mapping property of the tensor product, the linear map $f_\otimes: E_1 \otimes \dots \otimes E_n \rightarrow F$ such that $f = f_\otimes \circ \varphi$, is the desired map h . \square

In particular, when each I_k is finite and of size $m_k = \dim(E_k)$, we see that the dimension of the tensor product $E_1 \otimes \dots \otimes E_n$ is $m_1 \cdots m_n$. As a corollary of Proposition 33.12, if $(u_i^k)_{i \in I_k}$ is a basis for E_k , $1 \leq k \leq n$, then every tensor $z \in E_1 \otimes \dots \otimes E_n$ can be written in a unique way as

$$z = \sum_{(i_1, \dots, i_n) \in I_1 \times \dots \times I_n} \lambda_{i_1, \dots, i_n} u_{i_1}^1 \otimes \dots \otimes u_{i_n}^n,$$

for some unique family of scalars $\lambda_{i_1, \dots, i_n} \in K$, all zero except for a finite number.

33.4 Some Useful Isomorphisms for Tensor Products

Proposition 33.13. *Given three vector spaces E, F, G , there exists unique canonical isomorphisms*

(1) $E \otimes F \cong F \otimes E$

$$(2) \quad (E \otimes F) \otimes G \cong E \otimes (F \otimes G) \cong E \otimes F \otimes G$$

$$(3) \quad (E \oplus F) \otimes G \cong (E \otimes G) \oplus (F \otimes G)$$

$$(4) \quad K \otimes E \cong E$$

such that respectively

$$(a) \quad u \otimes v \mapsto v \otimes u$$

$$(b) \quad (u \otimes v) \otimes w \mapsto u \otimes (v \otimes w) \mapsto u \otimes v \otimes w$$

$$(c) \quad (u, v) \otimes w \mapsto (u \otimes w, v \otimes w)$$

$$(d) \quad \lambda \otimes u \mapsto \lambda u.$$

Proof. Except for (3), these isomorphisms are proved using the universal mapping property of tensor products.

(1) The map from $E \times F$ to $F \otimes E$ given by $(u, v) \mapsto v \otimes u$ is clearly bilinear, thus it induces a unique linear $\alpha: E \otimes F \rightarrow F \otimes E$ making the following diagram commute

$$\begin{array}{ccc} E \times F & \xrightarrow{\iota \otimes} & E \otimes F \\ & \searrow & \downarrow \alpha \\ & & F \otimes E, \end{array}$$

such that

$$\alpha(u \otimes v) = v \otimes u, \quad \text{for all } u \in E \text{ and all } v \in F.$$

Similarly, the map from $F \times E$ to $E \otimes F$ given by $(v, u) \mapsto u \otimes v$ is clearly bilinear, thus it induces a unique linear $\beta: F \otimes E \rightarrow E \otimes F$ making the following diagram commute

$$\begin{array}{ccc} F \times E & \xrightarrow{\iota \otimes} & F \otimes E \\ & \searrow & \downarrow \beta \\ & & E \otimes F, \end{array}$$

such that

$$\beta(v \otimes u) = u \otimes v, \quad \text{for all } u \in E \text{ and all } v \in F.$$

It is immediately verified that

$$(\beta \circ \alpha)(u \otimes v) = u \otimes v \quad \text{and} \quad (\alpha \circ \beta)(v \otimes u) = v \otimes u$$

for all $u \in E$ and all $v \in F$. Since the tensors of the form $u \otimes v$ span $E \otimes F$ and similarly the tensors of the form $v \otimes u$ span $F \otimes E$, the map $\beta \circ \alpha$ is actually the identity on $E \otimes F$, and similarly $\alpha \circ \beta$ is the identity on $F \otimes E$, so α and β are isomorphisms.

(2) Fix some $w \in G$. The map

$$(u, v) \mapsto u \otimes v \otimes w$$

from $E \times F$ to $E \otimes F \otimes G$ is bilinear, and thus there is a linear map $f_w: E \otimes F \rightarrow E \otimes F \otimes G$ making the following diagram commute

$$\begin{array}{ccc} E \times F & \xrightarrow{\iota \otimes} & E \otimes F \\ & \searrow & \downarrow f_w \\ & & E \otimes F \otimes G, \end{array}$$

with $f_w(u \otimes v) = u \otimes v \otimes w$.

Next consider the map

$$(z, w) \mapsto f_w(z),$$

from $(E \otimes F) \times G$ into $E \otimes F \otimes G$. It is easily seen to be bilinear, and thus it induces a linear map $f: (E \otimes F) \otimes G \rightarrow E \otimes F \otimes G$ making the following diagram commute

$$\begin{array}{ccc} (E \otimes F) \times G & \xrightarrow{\iota \otimes} & (E \otimes F) \otimes G \\ & \searrow & \downarrow f \\ & & E \otimes F \otimes G, \end{array}$$

with $f((u \otimes v) \otimes w) = u \otimes v \otimes w$.

Also consider the map

$$(u, v, w) \mapsto (u \otimes v) \otimes w$$

from $E \times F \times G$ to $(E \otimes F) \otimes G$. It is trilinear, and thus there is a linear map $g: E \otimes F \otimes G \rightarrow (E \otimes F) \otimes G$ making the following diagram commute

$$\begin{array}{ccc} E \times F \times G & \xrightarrow{\iota \otimes} & E \otimes F \otimes G \\ & \searrow & \downarrow g \\ & & (E \otimes F) \otimes G, \end{array}$$

with $g(u \otimes v \otimes w) = (u \otimes v) \otimes w$. Clearly, $f \circ g$ and $g \circ f$ are identity maps, and thus f and g are isomorphisms. The other case is similar.

(3) Given a fixed vector space G , for any two vector spaces M and N and every linear map $f: M \rightarrow N$, let $\tau_G(f) = f \otimes \text{id}_G$ be the unique linear map making the following diagram commute.

$$\begin{array}{ccc} M \times G & \xrightarrow{\iota_M \otimes} & M \otimes G \\ f \times \text{id}_G \downarrow & & \downarrow f \otimes \text{id}_G \\ N \times G & \xrightarrow{\iota_N \otimes} & N \otimes G \end{array}$$

The identity $(*)$ proved in Proposition 33.10 shows that if $g: N \rightarrow P$ is another linear map, then

$$\tau_G(g) \circ \tau_G(f) = (g \otimes \text{id}_G) \circ (f \otimes \text{id}_G) = (g \circ f) \otimes (\text{id}_G \circ \text{id}_G) = (g \circ f) \otimes \text{id}_G = \tau_G(g \circ f).$$

Clearly, $\tau_G(0) = 0$, and a direct computation on generators also shows that

$$\tau_G(\text{id}_M) = (\text{id}_M \otimes \text{id}_G) = \text{id}_{M \otimes G},$$

and that if $f': M \rightarrow N$ is another linear map, then

$$\tau_G(f + f') = \tau_G(f) + \tau_G(f').$$

In fancy terms, τ_G is a functor. Now, if $E \oplus F$ is a direct sum, it is a standard fact of linear algebra that if $\pi_E: E \oplus F \rightarrow E$ and $\pi_F: E \oplus F \rightarrow F$ are the projection maps, then

$$\pi_E \circ \pi_E = \pi_E \quad \pi_F \circ \pi_F = \pi_F \quad \pi_E \circ \pi_F = 0 \quad \pi_F \circ \pi_E = 0 \quad \pi_E + \pi_F = \text{id}_{E \oplus F}.$$

If we apply τ_G to these identities, we get

$$\begin{aligned} \tau_G(\pi_E) \circ \tau_G(\pi_E) &= \tau_G(\pi_E) & \tau_G(\pi_F) \circ \tau_G(\pi_F) &= \tau_G(\pi_F) \\ \tau_G(\pi_E) \circ \tau_G(\pi_F) &= 0 & \tau_G(\pi_F) \circ \tau_G(\pi_E) &= 0 & \tau_G(\pi_E) + \tau_G(\pi_F) &= \text{id}_{(E \oplus F) \otimes G}. \end{aligned}$$

Observe that $\tau_G(\pi_E) = \pi_E \otimes \text{id}_G$ is a map from $(E \oplus F) \otimes G$ onto $E \otimes G$ and that $\tau_G(\pi_F) = \pi_F \otimes \text{id}_G$ is a map from $(E \oplus F) \otimes G$ onto $F \otimes G$, and by linear algebra, the above equations mean that we have a direct sum

$$(E \otimes G) \oplus (F \otimes G) \cong (E \oplus F) \otimes G.$$

(4) We have the linear map $\epsilon: E \rightarrow K \otimes E$ given by

$$\epsilon(u) = 1 \otimes u, \quad \text{for all } u \in E.$$

The map $(\lambda, u) \mapsto \lambda u$ from $K \times E$ to E is bilinear, so it induces a unique linear map $\eta: K \otimes E \rightarrow E$ making the following diagram commute

$$\begin{array}{ccc} K \times E & \xrightarrow{\iota \otimes} & K \otimes E \\ & \searrow & \downarrow \eta \\ & & E, \end{array}$$

such that $\eta(\lambda \otimes u) = \lambda u$, for all $\lambda \in K$ and all $u \in E$. We have

$$(\eta \circ \epsilon)(u) = \eta(1 \otimes u) = 1u = u,$$

and

$$(\epsilon \circ \eta)(\lambda \otimes u) = \epsilon(\lambda u) = 1 \otimes (\lambda u) = \lambda(1 \otimes u) = \lambda \otimes u,$$

which shows that both $\epsilon \circ \eta$ and $\eta \circ \epsilon$ are the identity, so ϵ and η are isomorphisms. \square

Remark: The isomorphism (3) can be generalized to finite and even arbitrary direct sums $\bigoplus_{i \in I} E_i$ of vector spaces (where I is an arbitrary nonempty index set). We have an isomorphism

$$\left(\bigoplus_{i \in I} E_i \right) \otimes G \cong \bigoplus_{i \in I} (E_i \otimes G).$$

This isomorphism (with isomorphism (1)) can be used to give another proof of Proposition 33.12 (see Bertin [15], Chapter 4, Section 1) or Lang [109], Chapter XVI, Section 2).

Proposition 33.14. *Given any three vector spaces E, F, G , we have the canonical isomorphism*

$$\text{Hom}(E, F; G) \cong \text{Hom}(E, \text{Hom}(F, G)).$$

Proof. Any bilinear map $f: E \times F \rightarrow G$ gives the linear map $\varphi(f) \in \text{Hom}(E, \text{Hom}(F, G))$, where $\varphi(f)(u)$ is the linear map in $\text{Hom}(F, G)$ given by

$$\varphi(f)(u)(v) = f(u, v).$$

Conversely, given a linear map $g \in \text{Hom}(E, \text{Hom}(F, G))$, we get the bilinear map $\psi(g)$ given by

$$\psi(g)(u, v) = g(u)(v),$$

and it is clear that φ and ψ are mutual inverses. \square

Since by Proposition 33.7 there is a canonical isomorphism

$$\text{Hom}(E \otimes F, G) \cong \text{Hom}(E, F; G),$$

together with the isomorphism

$$\text{Hom}(E, F; G) \cong \text{Hom}(E, \text{Hom}(F, G))$$

given by Proposition 33.14, we obtain the important corollary:

Proposition 33.15. *For any three vector spaces E, F, G , we have the canonical isomorphism*

$$\text{Hom}(E \otimes F, G) \cong \text{Hom}(E, \text{Hom}(F, G)).$$

33.5 Duality for Tensor Products

In this section all vector spaces are assumed to have *finite dimension*, unless specified otherwise. Let us now see how tensor products behave under duality. For this, we define a pairing between $E_1^* \otimes \cdots \otimes E_n^*$ and $E_1 \otimes \cdots \otimes E_n$ as follows: For any fixed $(v_1^*, \dots, v_n^*) \in E_1^* \times \cdots \times E_n^*$, we have the multilinear map

$$l_{v_1^*, \dots, v_n^*}: (u_1, \dots, u_n) \mapsto v_1^*(u_1) \cdots v_n^*(u_n)$$

from $E_1 \times \cdots \times E_n$ to K . The map $l_{v_1^*, \dots, v_n^*}$ extends uniquely to a linear map $L_{v_1^*, \dots, v_n^*}: E_1 \otimes \cdots \otimes E_n \rightarrow K$ making the following diagram commute.

$$\begin{array}{ccc} E_1 \times \cdots \times E_n & \xrightarrow{\iota \otimes} & E_1 \otimes \cdots \otimes E_n \\ & \searrow l_{v_1^*, \dots, v_n^*} & \downarrow L_{v_1^*, \dots, v_n^*} \\ & & K \end{array}$$

We also have the multilinear map

$$(v_1^*, \dots, v_n^*) \mapsto L_{v_1^*, \dots, v_n^*}$$

from $E_1^* \times \cdots \times E_n^*$ to $\text{Hom}(E_1 \otimes \cdots \otimes E_n, K)$, which extends to a unique linear map L from $E_1^* \otimes \cdots \otimes E_n^*$ to $\text{Hom}(E_1 \otimes \cdots \otimes E_n, K)$ making the following diagram commute.

$$\begin{array}{ccc} E_1^* \times \cdots \times E_n^* & \xrightarrow{\iota \otimes} & E_1^* \otimes \cdots \otimes E_n^* \\ & \searrow L_{v_1^*, \dots, v_n^*} & \downarrow L \\ & & \text{Hom}(E_1 \otimes \cdots \otimes E_n; K) \end{array}$$

However, in view of the isomorphism

$$\text{Hom}(U \otimes V, W) \cong \text{Hom}(U, \text{Hom}(V, W))$$

given by Proposition 33.15, with $U = E_1^* \otimes \cdots \otimes E_n^*$, $V = E_1 \otimes \cdots \otimes E_n$ and $W = K$, we can view L as a linear map

$$L: (E_1^* \otimes \cdots \otimes E_n^*) \otimes (E_1 \otimes \cdots \otimes E_n) \rightarrow K,$$

which corresponds to a bilinear map

$$\langle -, - \rangle: (E_1^* \otimes \cdots \otimes E_n^*) \times (E_1 \otimes \cdots \otimes E_n) \rightarrow K, \quad (\dagger\dagger)$$

via the isomorphism $(U \otimes V)^* \cong \text{Hom}(U, V; K)$ given by Proposition 33.8. This pairing is given explicitly on generators by

$$\langle v_1^* \otimes \cdots \otimes v_n^*, u_1, \dots, u_n \rangle = v_1^*(u_1) \cdots v_n^*(u_n).$$

This pairing is nondegenerate, as proved below.

Proof. If $(e_1^1, \dots, e_{m_1}^1), \dots, (e_1^n, \dots, e_{m_n}^n)$ are bases for E_1, \dots, E_n , then for every basis element $(e_{i_1}^1)^* \otimes \cdots \otimes (e_{i_n}^n)^*$ of $E_1^* \otimes \cdots \otimes E_n^*$, and any basis element $e_{j_1}^1 \otimes \cdots \otimes e_{j_n}^n$ of $E_1 \otimes \cdots \otimes E_n$, we have

$$\langle (e_{i_1}^1)^* \otimes \cdots \otimes (e_{i_n}^n)^*, e_{j_1}^1 \otimes \cdots \otimes e_{j_n}^n \rangle = \delta_{i_1 j_1} \cdots \delta_{i_n j_n},$$

where δ_{ij} is *Kronecker delta*, defined such that $\delta_{ij} = 1$ if $i = j$, and 0 otherwise. Given any $\alpha \in E_1^* \otimes \cdots \otimes E_n^*$, assume that $\langle \alpha, \beta \rangle = 0$ for all $\beta \in E_1 \otimes \cdots \otimes E_n$. The vector α is a finite

linear combination $\alpha = \sum \lambda_{i_1, \dots, i_n} (e_{i_1}^1)^* \otimes \cdots \otimes (e_{i_n}^n)^*$, for some unique $\lambda_{i_1, \dots, i_n} \in K$. If we choose $\beta = e_{i_1}^1 \otimes \cdots \otimes e_{i_n}^n$, then we get

$$\begin{aligned} 0 &= \langle \alpha, e_{i_1}^1 \otimes \cdots \otimes e_{i_n}^n \rangle = \left\langle \sum \lambda_{i_1, \dots, i_n} (e_{i_1}^1)^* \otimes \cdots \otimes (e_{i_n}^n)^*, e_{i_1}^1 \otimes \cdots \otimes e_{i_n}^n \right\rangle \\ &= \sum \lambda_{i_1, \dots, i_n} \langle (e_{i_1}^1)^* \otimes \cdots \otimes (e_{i_n}^n)^*, e_{i_1}^1 \otimes \cdots \otimes e_{i_n}^n \rangle \\ &= \lambda_{i_1, \dots, i_n}. \end{aligned}$$

Therefore, $\alpha = 0$,

Conversely, given any $\beta \in E_1 \otimes \cdots \otimes E_n$, assume that $\langle \alpha, \beta \rangle = 0$, for all $\alpha \in E_1^* \otimes \cdots \otimes E_n^*$. The vector β is a finite linear combination $\beta = \sum \lambda_{i_1, \dots, i_n} e_{i_1}^1 \otimes \cdots \otimes e_{i_n}^n$, for some unique $\lambda_{i_1, \dots, i_n} \in K$. If we choose $\alpha = (e_{i_1}^1)^* \otimes \cdots \otimes (e_{i_n}^n)^*$, then we get

$$\begin{aligned} 0 &= \langle (e_{i_1}^1)^* \otimes \cdots \otimes (e_{i_n}^n)^*, \beta \rangle = \left\langle (e_{i_1}^1)^* \otimes \cdots \otimes (e_{i_n}^n)^*, \sum \lambda_{i_1, \dots, i_n} e_{i_1}^1 \otimes \cdots \otimes e_{i_n}^n \right\rangle \\ &= \sum \lambda_{i_1, \dots, i_n} \langle (e_{i_1}^1)^* \otimes \cdots \otimes (e_{i_n}^n)^*, e_{i_1}^1 \otimes \cdots \otimes e_{i_n}^n \rangle \\ &= \lambda_{i_1, \dots, i_n}. \end{aligned}$$

Therefore, $\beta = 0$. □

By Proposition 33.1,¹ we have a canonical isomorphism

$$(E_1 \otimes \cdots \otimes E_n)^* \cong E_1^* \otimes \cdots \otimes E_n^*.$$

Here is our main proposition about duality of tensor products.

Proposition 33.16. *We have canonical isomorphisms*

$$(E_1 \otimes \cdots \otimes E_n)^* \cong E_1^* \otimes \cdots \otimes E_n^*,$$

and

$$\mu: E_1^* \otimes \cdots \otimes E_n^* \cong \text{Hom}(E_1, \dots, E_n; K).$$

Proof. The second isomorphism follows from the isomorphism $(E_1 \otimes \cdots \otimes E_n)^* \cong E_1^* \otimes \cdots \otimes E_n^*$ together with the isomorphism $\text{Hom}(E_1, \dots, E_n; K) \cong (E_1 \otimes \cdots \otimes E_n)^*$ given by Proposition 33.8. □

Remarks:

1. The isomorphism $\mu: E_1^* \otimes \cdots \otimes E_n^* \cong \text{Hom}(E_1, \dots, E_n; K)$ can be described explicitly as the linear extension to $E_1^* \otimes \cdots \otimes E_n^*$ of the map given by

$$\mu(v_1^* \otimes \cdots \otimes v_n^*)(u_1, \dots, u_n) = v_1^*(u_1) \cdots v_n^*(u_n).$$

¹This is where the assumption that our spaces are finite-dimensional is used.

2. The canonical isomorphism of Proposition 33.16 holds under more general conditions. Namely, that K is a commutative ring with identity and that the E_i are finitely-generated projective K -modules (see Definition 35.7). See Bourbaki, [25] (Chapter III, §11, Section 5, Proposition 7).

We prove another useful canonical isomorphism that allows us to treat linear maps as tensors.

Let E and F be two vector spaces and let $\alpha: E^* \times F \rightarrow \text{Hom}(E, F)$ be the map defined such that

$$\alpha(u^*, f)(x) = u^*(x)f,$$

for all $u^* \in E^*$, $f \in F$, and $x \in E$. This map is clearly bilinear, and thus it induces a linear map $\alpha_{\otimes}: E^* \otimes F \rightarrow \text{Hom}(E, F)$ making the following diagram commute

$$\begin{array}{ccc} E^* \times F & \xrightarrow{\iota_{\otimes}} & E^* \otimes F \\ \alpha \searrow & & \downarrow \alpha_{\otimes} \\ & & \text{Hom}(E, F), \end{array}$$

such that

$$\alpha_{\otimes}(u^* \otimes f)(x) = u^*(x)f.$$

Proposition 33.17. *If E and F are vector spaces (not necessarily finite dimensional), then the following properties hold:*

- (1) *The linear map $\alpha_{\otimes}: E^* \otimes F \rightarrow \text{Hom}(E, F)$ is injective.*
- (2) *If E is finite-dimensional, then $\alpha_{\otimes}: E^* \otimes F \rightarrow \text{Hom}(E, F)$ is a canonical isomorphism.*
- (3) *If F is finite-dimensional, then $\alpha_{\otimes}: E^* \otimes F \rightarrow \text{Hom}(E, F)$ is a canonical isomorphism.*

Proof. (1) Let $(e_i^*)_{i \in I}$ be a basis of E^* and let $(f_j)_{j \in J}$ be a basis of F . Then we know that $(e_i^* \otimes f_j)_{i \in I, j \in J}$ is a basis of $E^* \otimes F$. To prove that α_{\otimes} is injective, let us show that its kernel is reduced to (0) . For any vector

$$\omega = \sum_{i \in I', j \in J'} \lambda_{ij} e_i^* \otimes f_j$$

in $E^* \otimes F$, with I' and J' some finite sets, assume that $\alpha_{\otimes}(\omega) = 0$. This means that for every $x \in E$, we have $\alpha_{\otimes}(\omega)(x) = 0$; that is,

$$\sum_{i \in I', j \in J'} \alpha_{\otimes}(\lambda_{ij} e_i^* \otimes f_j)(x) = \sum_{j \in J'} \left(\sum_{i \in I'} \lambda_{ij} e_i^*(x) \right) f_j = 0.$$

Since $(f_j)_{j \in J}$ is a basis of F , for every $j \in J'$, we must have

$$\sum_{i \in I'} \lambda_{ij} e_i^*(x) = 0, \quad \text{for all } x \in E.$$

But then $(e_i^*)_{i \in I'}$ would be linearly dependent, contradicting the fact that $(e_i^*)_{i \in I}$ is a basis of E^* , so we must have

$$\lambda_{ij} = 0, \quad \text{for all } i \in I' \text{ and all } j \in J',$$

which shows that $\omega = 0$. Therefore, α_\otimes is injective.

(2) Let $(e_j)_{1 \leq j \leq n}$ be a finite basis of E , and as usual, let $e_j^* \in E^*$ be the linear form defined by

$$e_j^*(e_k) = \delta_{j,k},$$

where $\delta_{j,k} = 1$ iff $j = k$ and 0 otherwise. We know that $(e_j^*)_{1 \leq j \leq n}$ is a basis of E^* (this is where we use the finite dimension of E). For any linear map $f \in \text{Hom}(E, F)$, for every $x = x_1 e_1 + \cdots + x_n e_n \in E$, we have

$$f(x) = f(x_1 e_1 + \cdots + x_n e_n) = x_1 f(e_1) + \cdots + x_n f(e_n) = e_1^*(x) f(e_1) + \cdots + e_n^*(x) f(e_n).$$

Consequently, every linear map $f \in \text{Hom}(E, F)$ can be expressed as

$$f(x) = e_1^*(x) f_1 + \cdots + e_n^*(x) f_n,$$

for some $f_i \in F$. Furthermore, if we apply f to e_i , we get $f(e_i) = f_i$, so the f_i are unique. Observe that

$$(\alpha_\otimes(e_1^* \otimes f_1 + \cdots + e_n^* \otimes f_n))(x) = \sum_{i=1}^n (\alpha_\otimes(e_i^* \otimes f_i))(x) = \sum_{i=1}^n e_i^*(x) f_i.$$

Thus, α_\otimes is surjective, so α_\otimes is a bijection.

(3) Let (f_1, \dots, f_m) be a finite basis of F , and let (f_1^*, \dots, f_m^*) be its dual basis. Given any linear map $h: E \rightarrow F$, for all $u \in E$, since $f_i^*(f_j) = \delta_{ij}$, we have

$$h(u) = \sum_{i=1}^m f_i^*(h(u)) f_i.$$

If

$$h(u) = \sum_{j=1}^m v_j^*(u) f_j \quad \text{for all } u \in E \tag{*}$$

for some linear forms $(v_1^*, \dots, v_m^*) \in (E^*)^m$, then

$$f_i^*(h(u)) = \sum_{j=1}^m v_j^*(u) f_i^*(f_j) = v_i^*(u) \quad \text{for all } u \in E,$$

which shows that $v_i^* = f_i^* \circ h$ for $i = 1, \dots, m$. This means that h has a unique expression in terms of linear forms as in (*). Define the map α from $(E^*)^m$ to $\text{Hom}(E, F)$ by

$$\alpha(v_1^*, \dots, v_m^*)(u) = \sum_{j=1}^m v_j^*(u) f_j \quad \text{for all } u \in E.$$

This map is linear. For any $h \in \text{Hom}(E, F)$, we showed earlier that the expression of h in (*) is unique, thus α is an isomorphism. Similarly, $E^* \otimes F$ is isomorphic to $(E^*)^m$. Any tensor $\omega \in E^* \otimes F$ can be written as a linear combination

$$\sum_{k=1}^p u_k^* \otimes y_k$$

for some $u_k^* \in E^*$ and some $y_k \in F$, and since (f_1, \dots, f_m) is a basis of F , each y_k can be written as a linear combination of (f_1, \dots, f_m) , so ω can be expressed as

$$\omega = \sum_{i=1}^m v_i^* \otimes f_i, \tag{\dagger}$$

for some linear forms $v_i^* \in E^*$ which are linear combinations of the u_k^* . If we pick a basis $(w_i^*)_{i \in I}$ for E^* , then we know that the family $(w_i^* \otimes f_j)_{i \in I, 1 \leq j \leq m}$ is a basis of $E^* \otimes F$, and this implies that the v_i^* in (\dagger) are unique. Define the linear map β from $(E^*)^m$ to $E^* \otimes F$ by

$$\beta(v_1^*, \dots, v_m^*) = \sum_{i=1}^m v_i^* \otimes f_i.$$

Since every tensor $\omega \in E^* \otimes F$ can be written in a unique way as in (\dagger), this map is an isomorphism. \square

Note that in Proposition 33.17, we have an isomorphism if either E or F has finite dimension. The following proposition allows us to view a multilinear as a tensor product.

Proposition 33.18. *If the E_1, \dots, E_n are finite-dimensional vector spaces and F is any vector space, then we have the canonical isomorphism*

$$\text{Hom}(E_1, \dots, E_n; F) \cong E_1^* \otimes \cdots \otimes E_n^* \otimes F.$$

Proof. In view of the canonical isomorphism

$$\text{Hom}(E_1, \dots, E_n; F) \cong \text{Hom}(E_1 \otimes \cdots \otimes E_n, F)$$

given by Proposition 33.7 and the canonical isomorphism $(E_1 \otimes \cdots \otimes E_n)^* \cong E_1^* \otimes \cdots \otimes E_n^*$ given by Proposition 33.16, if the E_i 's are finite-dimensional, then Proposition 33.17 yields the canonical isomorphism

$$\text{Hom}(E_1, \dots, E_n; F) \cong E_1^* \otimes \cdots \otimes E_n^* \otimes F,$$

as claimed. \square

33.6 Tensor Algebras

Our goal is to define a vector space $T(V)$ obtained by taking the direct sum of the tensor products

$$\underbrace{V \otimes \cdots \otimes V}_{m},$$

and to define a multiplication operation on $T(V)$ which makes $T(V)$ into an algebraic structure called an algebra. The algebra $T(V)$ satisfies a universal property stated in Proposition 33.19, which makes it the “free algebra” generated by the vector space V .

Definition 33.8. The tensor product

$$\underbrace{V \otimes \cdots \otimes V}_{m}$$

is also denoted as

$$\bigotimes^m V \quad \text{or} \quad V^{\otimes m}$$

and is called the m -th tensor power of V (with $V^{\otimes 1} = V$, and $V^{\otimes 0} = K$).

We can pack all the tensor powers of V into the “big” vector space

$$T(V) = \bigoplus_{m \geq 0} V^{\otimes m},$$

denoted $T^\bullet(V)$ or $\bigotimes V$ to avoid confusion with the tangent bundle.

This is an interesting object because we can define a multiplication operation on it which makes it into an *algebra*.

When V is of finite dimension n , we can pick some basis (e_1, \dots, e_n) of V , and then every tensor $\omega \in T(V)$ can be expressed as a linear combination of terms of the form $e_{i_1} \otimes \cdots \otimes e_{i_k}$, where (i_1, \dots, i_k) is any sequence of elements from the set $\{1, \dots, n\}$. We can think of the tensors $e_{i_1} \otimes \cdots \otimes e_{i_k}$ as monomials in the noncommuting variables e_1, \dots, e_n . Thus the space $T(V)$ corresponds to the algebra of polynomials with coefficients in K in n *noncommuting variables*.

Let us review the definition of an algebra over a field. Let K denote any (commutative) field, although for our purposes, we may assume that $K = \mathbb{R}$ (and occasionally, $K = \mathbb{C}$). Since we will only be dealing with associative algebras with a multiplicative unit, we only define algebras of this kind.

Definition 33.9. Given a field K , a K -*algebra* is a K -vector space A together with a bilinear operation $\cdot : A \times A \rightarrow A$, called *multiplication*, which makes A into a ring with unity 1 (or 1_A , when we want to be very precise). This means that \cdot is associative and that there is a multiplicative identity element 1 so that $1 \cdot a = a \cdot 1 = a$, for all $a \in A$. Given two

K -algebras A and B , a K -algebra homomorphism $h: A \rightarrow B$ is a linear map that is also a ring homomorphism, with $h(1_A) = 1_B$; that is,

$$\begin{aligned} h(a_1 \cdot a_2) &= h(a_1) \cdot h(a_2) \quad \text{for all } a_1, a_2 \in A \\ h(1_A) &= 1_B. \end{aligned}$$

The set of K -algebra homomorphisms between A and B is denoted $\text{Hom}_{\text{alg}}(A, B)$.

For example, the ring $M_n(K)$ of all $n \times n$ matrices over a field K is a K -algebra.

There is an obvious notion of ideal of a K -algebra.

Definition 33.10. Let A be a K -algebra. An *ideal* $\mathfrak{A} \subseteq A$ is a linear subspace of A that is also a two-sided ideal with respect to multiplication in A ; this means that for all $a \in \mathfrak{A}$ and all $\alpha, \beta \in A$, we have $\alpha a \beta \in \mathfrak{A}$.

If the field K is understood, we usually simply say an algebra instead of a K -algebra.

We would like to define a multiplication operation on $T(V)$ which makes it into a K -algebra. As

$$T(V) = \bigoplus_{i \geq 0} V^{\otimes i},$$

for every $i \geq 0$, there is a natural injection $\iota_n: V^{\otimes n} \rightarrow T(V)$, and in particular, an injection $\iota_0: K \rightarrow T(V)$. The multiplicative unit $\mathbf{1}$ of $T(V)$ is the image $\iota_0(1)$ in $T(V)$ of the unit 1 of the field K . Since every $v \in T(V)$ can be expressed as a finite sum

$$v = \iota_{n_1}(v_1) + \cdots + \iota_{n_k}(v_k),$$

where $v_i \in V^{\otimes n_i}$ and the n_i are natural numbers with $n_i \neq n_j$ if $i \neq j$, to define multiplication in $T(V)$, using bilinearity, it is enough to define multiplication operations $\cdot: V^{\otimes m} \times V^{\otimes n} \rightarrow V^{\otimes(m+n)}$, which, using the isomorphisms $V^{\otimes n} \cong \iota_n(V^{\otimes n})$, yield multiplication operations $\cdot: \iota_m(V^{\otimes m}) \times \iota_n(V^{\otimes n}) \rightarrow \iota_{m+n}(V^{\otimes(m+n)})$. First, for $\omega_1 \in V^{\otimes m}$ and $\omega_2 \in V^{\otimes n}$, we let

$$\omega_1 \cdot \omega_2 = \omega_1 \otimes \omega_2.$$

This defines a bilinear map so it defines a multiplication $V^{\otimes m} \times V^{\otimes n} \rightarrow V^{\otimes m} \otimes V^{\otimes n}$. This is not quite what we want, but there is a canonical isomorphism

$$V^{\otimes m} \otimes V^{\otimes n} \cong V^{\otimes(m+n)}$$

which yields the desired multiplication $\cdot: V^{\otimes m} \times V^{\otimes n} \rightarrow V^{\otimes(m+n)}$.

The isomorphism $V^{\otimes m} \otimes V^{\otimes n} \cong V^{\otimes(m+n)}$ can be established by induction using the isomorphism $(E \otimes F) \otimes G \cong E \otimes F \otimes G$. First we prove by induction on $m \geq 2$ that

$$V^{\otimes(m-1)} \otimes V \cong V^{\otimes m},$$

and then by induction on $n \geq 1$ than

$$V^{\otimes m} \otimes V^{\otimes n} \cong V^{\otimes(m+n)}.$$

In summary the multiplication $V^{\otimes m} \times V^{\otimes n} \rightarrow V^{\otimes(m+n)}$ is defined so that

$$(v_1 \otimes \cdots \otimes v_m) \cdot (w_1 \otimes \cdots \otimes w_n) = v_1 \otimes \cdots \otimes v_m \otimes w_1 \otimes \cdots \otimes w_n.$$

(This has to be made rigorous by using isomorphisms involving the associativity of tensor products, for details, see Jacobson [99], Section 3.9, or Bertin [15], Chapter 4, Section 2.)

Definition 33.11. Given a K -vector space V (not necessarily finite dimensional), the vector space

$$T(V) = \bigoplus_{m \geq 0} V^{\otimes m}$$

denoted $T^\bullet(V)$ or $\bigotimes V$ equipped with the multiplication operations $V^{\otimes m} \times V^{\otimes n} \rightarrow V^{\otimes(m+n)}$ defined above is called the *tensor algebra* of V .

Remark: It is important to note that multiplication in $T(V)$ is **not** commutative. Also, in all rigor, the unit $\mathbf{1}$ of $T(V)$ is **not equal** to 1, the unit of the field K . However, in view of the injection $\iota_0: K \rightarrow T(V)$, for the sake of notational simplicity, we will denote $\mathbf{1}$ by 1. More generally, in view of the injections $\iota_n: V^{\otimes n} \rightarrow T(V)$, we identify elements of $V^{\otimes n}$ with their images in $T(V)$.

The algebra $T(V)$ satisfies a universal mapping property which shows that it is unique up to isomorphism. For simplicity of notation, let $i: V \rightarrow T(V)$ be the natural injection of V into $T(V)$.

Proposition 33.19. *Given any K -algebra A , for any linear map $f: V \rightarrow A$, there is a unique K -algebra homomorphism $\bar{f}: T(V) \rightarrow A$ so that*

$$f = \bar{f} \circ i,$$

as in the diagram below.

$$\begin{array}{ccc} V & \xrightarrow{i} & T(V) \\ & \searrow f & \downarrow \bar{f} \\ & & A \end{array}$$

Proof. Left as an exercise (use Theorem 33.6). A proof can be found in Knapp [104] (Appendix A, Proposition A.14) or Bertin [15] (Chapter 4, Theorem 2.4). \square

Proposition 33.19 implies that there is a natural isomorphism

$$\text{Hom}_{\text{alg}}(T(V), A) \cong \text{Hom}(V, A),$$

where the algebra A on the right-hand side is viewed as a vector space. Proposition 33.19 also has the following corollary.

Proposition 33.20. *Given a linear map $h: V_1 \rightarrow V_2$ between two vectors spaces V_1, V_2 over a field K , there is a unique K -algebra homomorphism $\otimes h: T(V_1) \rightarrow T(V_2)$ making the following diagram commute.*

$$\begin{array}{ccc} V_1 & \xrightarrow{i_1} & T(V_1) \\ h \downarrow & & \downarrow \otimes h \\ V_2 & \xrightarrow{i_2} & T(V_2). \end{array}$$

Most algebras of interest arise as well-chosen quotients of the tensor algebra $T(V)$. This is true for the *exterior algebra* $\Lambda(V)$ (also called *Grassmann algebra*), where we take the quotient of $T(V)$ modulo the ideal generated by all elements of the form $v \otimes v$, where $v \in V$, and for the *symmetric algebra* $\text{Sym}(V)$, where we take the quotient of $T(V)$ modulo the ideal generated by all elements of the form $v \otimes w - w \otimes v$, where $v, w \in V$.

Algebras such as $T(V)$ are graded in the sense that there is a sequence of subspaces $V^{\otimes n} \subseteq T(V)$ such that

$$T(V) = \bigoplus_{k \geq 0} V^{\otimes n},$$

and the multiplication \otimes behaves well w.r.t. the grading, i.e., $\otimes: V^{\otimes m} \times V^{\otimes n} \rightarrow V^{\otimes(m+n)}$.

Definition 33.12. A K -algebra E is said to be a *graded algebra* iff there is a sequence of subspaces $E^n \subseteq E$ such that

$$E = \bigoplus_{k \geq 0} E^n,$$

(with $E^0 = K$) and the multiplication \cdot respects the grading; that is, $\cdot: E^m \times E^n \rightarrow E^{m+n}$. Elements in E^n are called *homogeneous elements of rank (or degree) n* .

In differential geometry and in physics it is necessary to consider slightly more general tensors.

Definition 33.13. Given a vector space V , for any pair of nonnegative integers (r, s) , the *tensor space* $T^{r,s}(V)$ of type (r, s) is the tensor product

$$T^{r,s}(V) = V^{\otimes r} \otimes (V^*)^{\otimes s} = \underbrace{V \otimes \cdots \otimes V}_r \otimes \underbrace{V^* \otimes \cdots \otimes V^*}_s,$$

with $T^{0,0}(V) = K$. We also define the *tensor algebra* $T^{\bullet,\bullet}(V)$ as the direct sum (coproduct)

$$T^{\bullet,\bullet}(V) = \bigoplus_{r,s \geq 0} T^{r,s}(V).$$

Tensors in $T^{r,s}(V)$ are called *homogeneous of degree (r, s)* .

Note that tensors in $T^{r,0}(V)$ are just our “old tensors” in $V^{\otimes r}$. We make $T^{\bullet,\bullet}(V)$ into an algebra by defining multiplication operations

$$T^{r_1,s_1}(V) \times T^{r_2,s_2}(V) \longrightarrow T^{r_1+r_2,s_1+s_2}(V)$$

in the usual way, namely: For $u = u_1 \otimes \cdots \otimes u_{r_1} \otimes u_1^* \otimes \cdots \otimes u_{s_1}^*$ and $v = v_1 \otimes \cdots \otimes v_{r_2} \otimes v_1^* \otimes \cdots \otimes v_{s_2}^*$, let

$$u \otimes v = u_1 \otimes \cdots \otimes u_{r_1} \otimes v_1 \otimes \cdots \otimes v_{r_2} \otimes u_1^* \otimes \cdots \otimes u_{s_1}^* \otimes v_1^* \otimes \cdots \otimes v_{s_2}^*.$$

Denote by $\text{Hom}(V^r, (V^*)^s; W)$ the vector space of all multilinear maps from $V^r \times (V^*)^s$ to W . Then we have the universal mapping property which asserts that there is a canonical isomorphism

$$\text{Hom}(T^{r,s}(V), W) \cong \text{Hom}(V^r, (V^*)^s; W).$$

In particular,

$$(T^{r,s}(V))^* \cong \text{Hom}(V^r, (V^*)^s; K).$$

For finite dimensional vector spaces, the duality of Section 33.5 is also easily extended to the tensor spaces $T^{r,s}(V)$. We define the pairing

$$T^{r,s}(V^*) \times T^{r,s}(V) \longrightarrow K$$

as follows: if

$$v^* = v_1^* \otimes \cdots \otimes v_r^* \otimes u_{r+1} \otimes \cdots \otimes u_{r+s} \in T^{r,s}(V^*)$$

and

$$u = u_1 \otimes \cdots \otimes u_r \otimes v_{r+1}^* \otimes \cdots \otimes v_{r+s}^* \in T^{r,s}(V),$$

then

$$(v^*, u) = v_1^*(u_1) \cdots v_{r+s}^*(u_{r+s}).$$

This is a nondegenerate pairing, and thus we get a canonical isomorphism

$$(T^{r,s}(V))^* \cong T^{r,s}(V^*).$$

Consequently, we get a canonical isomorphism

$$T^{r,s}(V^*) \cong \text{Hom}(V^r, (V^*)^s; K).$$

We summarize these results in the following proposition.

Proposition 33.21. *Let V be a vector space and let*

$$T^{r,s}(V) = V^{\otimes r} \otimes (V^*)^{\otimes s} = \underbrace{V \otimes \cdots \otimes V}_r \otimes \underbrace{V^* \otimes \cdots \otimes V^*}_s.$$

We have the canonical isomorphisms

$$(T^{r,s}(V))^* \cong T^{r,s}(V^*),$$

and

$$T^{r,s}(V^*) \cong \text{Hom}(V^r, (V^*)^s; K).$$

Remark: The tensor spaces, $T^{r,s}(V)$ are also denoted $T_s^r(V)$. A tensor $\alpha \in T^{r,s}(V)$ is said to be *contravariant* in the first r arguments and *covariant* in the last s arguments. This terminology refers to the way tensors behave under coordinate changes. Given a basis (e_1, \dots, e_n) of V , if (e_1^*, \dots, e_n^*) denotes the dual basis, then every tensor $\alpha \in T^{r,s}(V)$ is given by an expression of the form

$$\alpha = \sum_{\substack{i_1, \dots, i_r \\ j_1, \dots, j_s}} a_{j_1, \dots, j_s}^{i_1, \dots, i_r} e_{i_1} \otimes \cdots \otimes e_{i_r} \otimes e_{j_1}^* \otimes \cdots \otimes e_{j_s}^*.$$

The tradition in classical tensor notation is to use lower indices on vectors and upper indices on linear forms and in accordance to *Einstein summation convention* (or *Einstein notation*) the position of the indices on the coefficients is reversed. *Einstein summation convention* (already encountered in Section 33.1) is to assume that a summation is performed for all values of every index that appears simultaneously once as an upper index and once as a lower index. According to this convention, the tensor α above is written

$$\alpha = a_{j_1, \dots, j_s}^{i_1, \dots, i_r} e_{i_1} \otimes \cdots \otimes e_{i_r} \otimes e^{j_1} \otimes \cdots \otimes e^{j_s}.$$

An older view of tensors is that they are multidimensional arrays of coefficients,

$$(a_{j_1, \dots, j_s}^{i_1, \dots, i_r}),$$

subject to the rules for changes of bases.

Another operation on general tensors, contraction, is useful in differential geometry.

Definition 33.14. For all $r, s \geq 1$, the *contraction* $c_{i,j}: T^{r,s}(V) \rightarrow T^{r-1,s-1}(V)$, with $1 \leq i \leq r$ and $1 \leq j \leq s$, is the linear map defined on generators by

$$\begin{aligned} c_{i,j}(u_1 \otimes \cdots \otimes u_r \otimes v_1^* \otimes \cdots \otimes v_s^*) \\ = v_j^*(u_i) u_1 \otimes \cdots \otimes \widehat{u_i} \otimes \cdots \otimes u_r \otimes v_1^* \otimes \cdots \otimes \widehat{v_j^*} \otimes \cdots \otimes v_s^*, \end{aligned}$$

where the hat over an argument means that it should be omitted.

Let us figure our what is $c_{1,1}: T^{1,1}(V) \rightarrow \mathbb{R}$, that is $c_{1,1}: V \otimes V^* \rightarrow \mathbb{R}$. If (e_1, \dots, e_n) is a basis of V and (e_1^*, \dots, e_n^*) is the dual basis, by Proposition 33.17 every $h \in V \otimes V^* \cong \text{Hom}(V, V)$ can be expressed as

$$h = \sum_{i,j=1}^n a_{ij} e_i \otimes e_j^*.$$

As

$$c_{1,1}(e_i \otimes e_j^*) = \delta_{i,j},$$

we get

$$c_{1,1}(h) = \sum_{i=1}^n a_{ii} = \text{tr}(h),$$

where $\text{tr}(h)$ is the *trace* of h , where h is viewed as the linear map given by the matrix, (a_{ij}) . Actually, since $c_{1,1}$ is defined independently of any basis, $c_{1,1}$ provides an intrinsic definition of the trace of a linear map $h \in \text{Hom}(V, V)$.

Remark: Using the Einstein summation convention, if

$$\alpha = a_{j_1, \dots, j_s}^{i_1, \dots, i_r} e_{i_1} \otimes \cdots \otimes e_{i_r} \otimes e^{j_1} \otimes \cdots \otimes e^{j_s},$$

then

$$c_{k,l}(\alpha) = a_{j_1, \dots, j_{l-1}, j_l+1, \dots, j_s}^{i_1, \dots, i_{k-1}, i_k+1, \dots, i_r} e_{i_1} \otimes \cdots \otimes \widehat{e_{i_k}} \otimes \cdots \otimes e_{i_r} \otimes e^{j_1} \otimes \cdots \otimes \widehat{e^{j_l}} \otimes \cdots \otimes e^{j_s}.$$

If E and F are two K -algebras, we know that their tensor product $E \otimes F$ exists as a vector space. We can make $E \otimes F$ into an algebra as well. Indeed, we have the multilinear map

$$E \times F \times E \times F \longrightarrow E \otimes F$$

given by $(a, b, c, d) \mapsto (ac) \otimes (bd)$, where ac is the product of a and c in E and bd is the product of b and d in F . By the universal mapping property, we get a linear map,

$$E \otimes F \otimes E \otimes F \longrightarrow E \otimes F.$$

Using the isomorphism

$$E \otimes F \otimes E \otimes F \cong (E \otimes F) \otimes (E \otimes F),$$

we get a linear map

$$(E \otimes F) \otimes (E \otimes F) \longrightarrow E \otimes F,$$

and thus a bilinear map,

$$(E \otimes F) \times (E \otimes F) \longrightarrow E \otimes F$$

which is our multiplication operation in $E \otimes F$. This multiplication is determined by

$$(a \otimes b) \cdot (c \otimes d) = (ac) \otimes (bd).$$

In summary we have the following proposition.

Proposition 33.22. *Given two K -algebra E and F , the operation on $E \otimes F$ defined on generators by*

$$(a \otimes b) \cdot (c \otimes d) = (ac) \otimes (bd)$$

makes $E \otimes F$ into a K -algebra.

We now turn to symmetric tensors.

33.7 Symmetric Tensor Powers

Our goal is to come up with a notion of tensor product that will allow us to treat symmetric multilinear maps as linear maps. Note that we have to restrict ourselves to a *single* vector space E , rather than n vector spaces E_1, \dots, E_n , so that symmetry makes sense.

Definition 33.15. A multilinear map $f: E^n \rightarrow F$ is *symmetric* iff

$$f(u_{\sigma(1)}, \dots, u_{\sigma(n)}) = f(u_1, \dots, u_n),$$

for all $u_i \in E$ and all permutations, $\sigma: \{1, \dots, n\} \rightarrow \{1, \dots, n\}$. The group of permutations on $\{1, \dots, n\}$ (the *symmetric group*) is denoted \mathfrak{S}_n . The vector space of all symmetric multilinear maps $f: E^n \rightarrow F$ is denoted by $\text{Sym}^n(E; F)$ or $\text{Hom}_{\text{symlin}}(E^n, F)$. Note that $\text{Sym}^1(E; F) = \text{Hom}(E, F)$.

We could proceed directly as in Theorem 33.6 and construct symmetric tensor products from scratch. However, since we already have the notion of a tensor product, there is a more economical method. First we define symmetric tensor powers.

Definition 33.16. An n -th *symmetric tensor power* of a vector space E , where $n \geq 1$, is a vector space S together with a symmetric multilinear map $\varphi: E^n \rightarrow S$ such that, for every vector space F and for every symmetric multilinear map $f: E^n \rightarrow F$, there is a unique linear map $f_\odot: S \rightarrow F$, with

$$f(u_1, \dots, u_n) = f_\odot(\varphi(u_1, \dots, u_n)),$$

for all $u_1, \dots, u_n \in E$, or for short

$$f = f_\odot \circ \varphi.$$

Equivalently, there is a unique linear map f_\odot such that the following diagram commutes.

$$\begin{array}{ccc} E^n & \xrightarrow{\varphi} & S \\ & \searrow f & \downarrow f_\odot \\ & & F \end{array}$$

The above property is called the *universal mapping property* of the symmetric tensor power (S, φ) .

We next show that any two symmetric n -th tensor powers (S_1, φ_1) and (S_2, φ_2) for E are isomorphic.

Proposition 33.23. *Given any two symmetric n -th tensor powers (S_1, φ_1) and (S_2, φ_2) for E , there is an isomorphism $h: S_1 \rightarrow S_2$ such that*

$$\varphi_2 = h \circ \varphi_1.$$

Proof. Replace tensor product by n -th symmetric tensor power in the proof of Proposition 33.5. \square

We now give a construction that produces a symmetric n -th tensor power of a vector space E .

Theorem 33.24. *Given a vector space E , a symmetric n -th tensor power $(S^n(E), \varphi)$ for E can be constructed ($n \geq 1$). Furthermore, denoting $\varphi(u_1, \dots, u_n)$ as $u_1 \odot \cdots \odot u_n$, the symmetric tensor power $S^n(E)$ is generated by the vectors $u_1 \odot \cdots \odot u_n$, where $u_1, \dots, u_n \in E$, and for every symmetric multilinear map $f: E^n \rightarrow F$, the unique linear map $f_\odot: S^n(E) \rightarrow F$ such that $f = f_\odot \circ \varphi$ is defined by*

$$f_\odot(u_1 \odot \cdots \odot u_n) = f(u_1, \dots, u_n)$$

on the generators $u_1 \odot \cdots \odot u_n$ of $S^n(E)$.

Proof. The tensor power $E^{\otimes n}$ is too big, and thus we define an appropriate quotient. Let C be the subspace of $E^{\otimes n}$ generated by the vectors of the form

$$u_1 \otimes \cdots \otimes u_n - u_{\sigma(1)} \otimes \cdots \otimes u_{\sigma(n)},$$

for all $u_i \in E$, and all permutations $\sigma: \{1, \dots, n\} \rightarrow \{1, \dots, n\}$. We claim that the quotient space $(E^{\otimes n})/C$ does the job.

Let $p: E^{\otimes n} \rightarrow (E^{\otimes n})/C$ be the quotient map, and let $\varphi: E^n \rightarrow (E^{\otimes n})/C$ be the map given by

$$\varphi = p \circ \varphi_0,$$

where $\varphi_0: E^n \rightarrow E^{\otimes n}$ is the injection given by $\varphi_0(u_1, \dots, u_n) = u_1 \otimes \cdots \otimes u_n$.

Let us denote $\varphi(u_1, \dots, u_n)$ as $u_1 \odot \cdots \odot u_n$. It is clear that φ is symmetric. Since the vectors $u_1 \otimes \cdots \otimes u_n$ generate $E^{\otimes n}$, and p is surjective, the vectors $u_1 \odot \cdots \odot u_n$ generate $(E^{\otimes n})/C$.

It remains to show that $((E^{\otimes n})/C, \varphi)$ satisfies the universal mapping property. To this end we begin by proving that there is a map h such that $f = h \circ \varphi$. Given any symmetric multilinear map $f: E^n \rightarrow F$, by Theorem 33.6 there is a linear map $f_\otimes: E^{\otimes n} \rightarrow F$ such that $f = f_\otimes \circ \varphi_0$, as in the diagram below.

$$\begin{array}{ccc} E^n & \xrightarrow{\varphi_0} & E^{\otimes n} \\ & \searrow f & \downarrow f_\otimes \\ & & F \end{array}$$

However, since f is symmetric, we have $f_{\otimes}(z) = 0$ for every $z \in C$. Thus, we get an induced linear map $h: (E^{\otimes n})/C \rightarrow F$ making the following diagram commute.

$$\begin{array}{ccccc}
 & & E^{\otimes n} & & \\
 & \varphi_0 \nearrow & \downarrow f_{\otimes} & \searrow p & \\
 E^n & & & & (E^{\otimes n})/C \\
 & f \searrow & \downarrow & \swarrow h & \\
 & & F & &
 \end{array}$$

If we define $h([z]) = f_{\otimes}(z)$ for every $z \in E^{\otimes n}$, where $[z]$ is the equivalence class in $(E^{\otimes n})/C$ of $z \in E^{\otimes n}$, the above diagram shows that $f = h \circ p \circ \varphi_0 = h \circ \varphi$. We now prove the uniqueness of h . For any linear map $f_{\odot}: (E^{\otimes n})/C \rightarrow F$ such that $f = f_{\odot} \circ \varphi$, since $\varphi(u_1, \dots, u_n) = u_1 \odot \dots \odot u_n$ and the vectors $u_1 \odot \dots \odot u_n$ generate $(E^{\otimes n})/C$, the map f_{\odot} is uniquely defined by

$$f_{\odot}(u_1 \odot \dots \odot u_n) = f(u_1, \dots, u_n).$$

Since $f = h \circ \varphi$, the map h is unique, and we let $f_{\odot} = h$. Thus, $S^n(E) = (E^{\otimes n})/C$ and φ constitute a symmetric n -th tensor power of E . \square

The map φ from E^n to $S^n(E)$ is often denoted ι_{\odot} , so that

$$\iota_{\odot}(u_1, \dots, u_n) = u_1 \odot \dots \odot u_n.$$

Again, the actual construction is not important. What is important is that the symmetric n -th power has the universal mapping property with respect to symmetric multilinear maps.

Remark: The notation \odot for the commutative multiplication of symmetric tensor powers is not standard. Another notation commonly used is \cdot . We often abbreviate “symmetric tensor power” as “symmetric power.” The symmetric power $S^n(E)$ is also denoted $\text{Sym}^n E$ but we prefer to use the notation Sym to denote spaces of symmetric multilinear maps. To be consistent with the use of \odot , we could have used the notation $\bigodot^n E$. Clearly, $S^1(E) \cong E$ and it is convenient to set $S^0(E) = K$.

The fact that the map $\varphi: E^n \rightarrow S^n(E)$ is symmetric and multilinear can also be expressed as follows:

$$u_1 \odot \dots \odot (v_i + w_i) \odot \dots \odot u_n = (u_1 \odot \dots \odot v_i \odot \dots \odot u_n) + (u_1 \odot \dots \odot w_i \odot \dots \odot u_n),$$

$$u_1 \odot \dots \odot (\lambda u_i) \odot \dots \odot u_n = \lambda(u_1 \odot \dots \odot u_i \odot \dots \odot u_n),$$

$$u_{\sigma(1)} \odot \dots \odot u_{\sigma(n)} = u_1 \odot \dots \odot u_n,$$

for all permutations $\sigma \in \mathfrak{S}_n$.

The last identity shows that the “operation” \odot is commutative. This allows us to view the symmetric tensor $u_1 \odot \dots \odot u_n$ as an object called a multiset.

Given a set A , a multiset with elements from A is a generalization of the concept of a set that allows multiple instances of elements from A to occur. For example, if $A = \{a, b, c, d\}$, the following are multisets:

$$M_1 = \{a, a, b\}, \quad M_2 = \{a, a, b, b, c\}, \quad M_3 = \{a, a, b, b, c, d, d, d\}.$$

Here is another way to represent multisets as tables showing the multiplicities of the elements in the multiset:

$$M_1 = \begin{pmatrix} a & b & c & d \\ 2 & 1 & 0 & 0 \end{pmatrix}, \quad M_2 = \begin{pmatrix} a & b & c & d \\ 2 & 2 & 1 & 0 \end{pmatrix}, \quad M_3 = \begin{pmatrix} a & b & c & d \\ 2 & 2 & 1 & 3 \end{pmatrix}.$$

The above are just graphs of functions from the set $A = \{a, b, c, d\}$ to \mathbb{N} . This suggests the following definition.

Definition 33.17. A finite *multiset* M over a set A is a function $M: A \rightarrow \mathbb{N}$ such that $M(a) \neq 0$ for finitely many $a \in A$. The *multiplicity* of an element $a \in A$ in M is $M(a)$. The set of all multisets over A is denoted by $\mathbb{N}^{(A)}$, and we let $\text{dom}(M) = \{a \in A \mid M(a) \neq 0\}$, which is a finite set. The set $\text{dom}(M)$ is the set of elements in A that actually occur in M . For any multiset $M \in \mathbb{N}^{(A)}$, note that $\sum_{a \in A} M(a)$ makes sense, since $\sum_{a \in A} M(a) = \sum_{a \in \text{dom}(A)} M(a)$, and $\text{dom}(M)$ is finite; this sum is the total number of elements in the multiset A and is called the *size* of M . Let $|M| = \sum_{a \in A} M(a)$.

Going back to our symmetric tensors, we can view the tensors of the form $u_1 \odot \cdots \odot u_n$ as multisets of size n over the set E .

Theorem 33.24 implies the following proposition.

Proposition 33.25. *There is a canonical isomorphism*

$$\text{Hom}(\text{S}^n(E), F) \cong \text{Sym}^n(E; F),$$

between the vector space of linear maps $\text{Hom}(\text{S}^n(E), F)$ and the vector space of symmetric multilinear maps $\text{Sym}^n(E; F)$ given by the linear map $- \circ \varphi$ defined by $h \mapsto h \circ \varphi$, with $h \in \text{Hom}(\text{S}^n(E), F)$.

Proof. The map $h \circ \varphi$ is clearly symmetric multilinear. By Theorem 33.24, for every symmetric multilinear map $f \in \text{Sym}^n(E; F)$ there is a unique linear map $f_\odot \in \text{Hom}(\text{S}^n(E), F)$ such that $f = f_\odot \circ \varphi$, so the map $- \circ \varphi$ is bijective. Its inverse is the map $f \mapsto f_\odot$. \square

In particular, when $F = K$, we get the following important fact.

Proposition 33.26. *There is a canonical isomorphism*

$$(\text{S}^n(E))^* \cong \text{Sym}^n(E; K).$$

Definition 33.18. Symmetric tensors in $S^n(E)$ are called *symmetric n-tensors*, and tensors of the form $u_1 \odot \cdots \odot u_n$, where $u_i \in E$, are called *simple (or decomposable) symmetric n-tensors*. Those symmetric n -tensors that are not simple are often called *compound symmetric n-tensors*.

Given linear map $f: E \rightarrow E'$, since the map $\iota'_\odot \circ (f \times f)$ is bilinear and symmetric, there is a unique linear map $f \odot f: S^2(E) \rightarrow S^2(E')$ making the following diagram commute.

$$\begin{array}{ccc} E^2 & \xrightarrow{\iota_\odot} & S^2(E) \\ f \times f \downarrow & & \downarrow f \odot f \\ (E')^2 & \xrightarrow{\iota'_\odot} & S^2(E'). \end{array}$$

Observe that $f \odot g$ is determined by

$$(f \odot g)(u \odot v) = f(u) \odot g(v).$$

Proposition 33.27. *Given any two linear maps $f: E \rightarrow E'$ and $f': E' \rightarrow E''$, we have*

$$(f' \circ f) \odot (f' \circ f) = (f' \odot f') \circ (f \odot f).$$

The generalization to the symmetric tensor product $f \odot \cdots \odot f$ of $n \geq 3$ copies of the linear map $f: E \rightarrow E'$ is immediate, and left to the reader.

33.8 Bases of Symmetric Powers

The vectors $u_1 \odot \cdots \odot u_m$ where $u_1, \dots, u_m \in E$ generate $S^m(E)$, but they are not linearly independent. We will prove a version of Proposition 33.12 for symmetric tensor powers using multisets.

Recall that a (finite) multiset over a set I is a function $M: I \rightarrow \mathbb{N}$, such that $M(i) \neq 0$ for finitely many $i \in I$. The set of all multisets over I is denoted as $\mathbb{N}^{(I)}$ and we let $\text{dom}(M) = \{i \in I \mid M(i) \neq 0\}$, the finite set of elements in I that actually occur in M . The size of the multiset M is $|M| = \sum_{a \in A} M(a)$.

To explain the idea of the proof, consider the case when $m = 2$ and E has dimension 3. Given a basis (e_1, e_2, e_3) of E , we would like to prove that

$$e_1 \odot e_1, \quad e_1 \odot e_2, \quad e_1 \odot e_3, \quad e_2 \odot e_2, \quad e_2 \odot e_3, \quad e_3 \odot e_3$$

are linearly independent. To prove this, it suffices to show that for any vector space F , if $w_{11}, w_{12}, w_{13}, w_{22}, w_{23}, w_{33}$ are any vectors in F , then there is a symmetric bilinear map $h: E^2 \rightarrow F$ such that

$$h(e_i, e_j) = w_{ij}, \quad 1 \leq i \leq j \leq 3.$$

Because h yields a unique linear map $h_{\odot}: S^2(E) \rightarrow F$ such that

$$h_{\odot}(e_i \odot e_j) = w_{ij}, \quad 1 \leq i \leq j \leq 3,$$

by Proposition 33.4, the vectors

$$e_1 \odot e_1, \quad e_1 \odot e_2, \quad e_1 \odot e_3, \quad e_2 \odot e_2, \quad e_2 \odot e_3, \quad e_3 \odot e_3$$

are linearly independent. This suggests understanding how a symmetric bilinear function $f: E^2 \rightarrow F$ is expressed in terms of its values $f(e_i, e_j)$ on the basis vectors (e_1, e_2, e_3) , and this can be done easily. Using bilinearity and symmetry, we obtain

$$\begin{aligned} f(u_1 e_1 + u_2 e_2 + u_3 e_3, v_1 e_1 + v_2 e_2 + v_3 e_3) &= u_1 v_1 f(e_1, e_1) + (u_1 v_2 + u_2 v_1) f(e_1, e_2) \\ &\quad + (u_1 v_3 + u_3 v_1) f(e_1, e_3) + u_2 v_2 f(e_2, e_2) \\ &\quad + (u_2 v_3 + u_3 v_2) f(e_2, e_3) + u_3 v_3 f(e_3, e_3). \end{aligned}$$

Therefore, given $w_{11}, w_{12}, w_{13}, w_{22}, w_{23}, w_{33} \in F$, the function h given by

$$\begin{aligned} h(u_1 e_1 + u_2 e_2 + u_3 e_3, v_1 e_1 + v_2 e_2 + v_3 e_3) &= u_1 v_1 w_{11} + (u_1 v_2 + u_2 v_1) w_{12} \\ &\quad + (u_1 v_3 + u_3 v_1) w_{13} + u_2 v_2 w_{22} \\ &\quad + (u_2 v_3 + u_3 v_2) w_{23} + u_3 v_3 w_{33} \end{aligned}$$

is clearly bilinear symmetric, and by construction $h(e_i, e_j) = w_{ij}$, so it does the job.

The generalization of this argument to any $m \geq 2$ and to a space E of any dimension (even infinite) is conceptually clear, but notationally messy. If $\dim(E) = n$ and if (e_1, \dots, e_n) is a basis of E , for any m vectors $v_j = \sum_{i=1}^n u_{i,j} e_i$ in E , for any symmetric multilinear map $f: E^m \rightarrow F$, we have

$$\begin{aligned} f(v_1, \dots, v_m) &= \sum_{k_1 + \dots + k_n = m} \left(\sum_{\substack{I_1 \cup \dots \cup I_n = \{1, \dots, m\} \\ I_i \cap I_j = \emptyset, i \neq j, |I_j| = k_j}} \left(\prod_{i_1 \in I_1} u_{1,i_1} \right) \dots \left(\prod_{i_n \in I_n} u_{n,i_n} \right) \right) f(\underbrace{e_1, \dots, e_1}_{k_1}, \dots, \underbrace{e_n, \dots, e_n}_{k_n}). \end{aligned}$$

Definition 33.19. Given any set J of $n \geq 1$ elements, say $J = \{j_1, \dots, j_n\}$, and given any $m \geq 2$, for any sequence (k_1, \dots, k_n) of natural numbers $k_i \in \mathbb{N}$ such that $k_1 + \dots + k_n = m$, the multiset M of size m

$$M = \{\underbrace{j_1, \dots, j_1}_{k_1}, \underbrace{j_2, \dots, j_2}_{k_2}, \dots, \underbrace{j_n, \dots, j_n}_{k_n}\}$$

is denoted by $M(m, J, k_1, \dots, k_n)$. Note that $M(j_i) = k_i$, for $i = 1, \dots, n$. Given any $k \geq 1$, and any $u \in E$, we denote $\underbrace{u \odot \dots \odot u}_k$ as $u^{\odot k}$.

We can now prove the following proposition.

Proposition 33.28. *Given a vector space E , if $(e_i)_{i \in I}$ is a basis for E , then the family of vectors*

$$\left(e_{i_1}^{\odot M(i_1)} \odot \cdots \odot e_{i_k}^{\odot M(i_k)} \right)_{\substack{M \in \mathbb{N}^{(I)}, |M|=m, \\ \{i_1, \dots, i_k\} = \text{dom}(M)}}$$

is a basis of the symmetric m -th tensor power $S^m(E)$.

Proof. The proof is very similar to that of Proposition 33.12. First assume that E has finite dimension n . In this case $I = \{1, \dots, n\}$, and any multiset $M \in \mathbb{N}^{(I)}$ of size $|M| = m$ is of the form $M(m, \{1, \dots, n\}, k_1, \dots, k_n)$, with $k_i = M(i)$ and $k_1 + \cdots + k_n = m$.

For any nontrivial vector space F , for any family of vectors

$$(w_M)_{M \in \mathbb{N}^{(I)}, |M|=m},$$

we show the existence of a symmetric multilinear map $h: S^m(E) \rightarrow F$, such that for every $M \in \mathbb{N}^{(I)}$ with $|M| = m$, we have

$$h(e_{i_1}^{\odot M(i_1)} \odot \cdots \odot e_{i_k}^{\odot M(i_k)}) = w_M,$$

where $\{i_1, \dots, i_k\} = \text{dom}(M)$. We define the map $f: E^m \rightarrow F$ as follows: for any m vectors $v_1, \dots, v_m \in E$ we can write $v_k = \sum_{i=1}^n u_{i,k} e_i$ for $k = 1, \dots, m$ and we set

$$\begin{aligned} f(v_1, \dots, v_m) &= \sum_{k_1+\cdots+k_n=m} \left(\sum_{\substack{I_1 \cup \cdots \cup I_n = \{1, \dots, m\} \\ I_i \cap I_j = \emptyset, i \neq j, |I_j|=k_j}} \left(\prod_{i_1 \in I_1} u_{1,i_1} \right) \cdots \left(\prod_{i_n \in I_n} u_{n,i_n} \right) \right) w_{M(m, \{1, \dots, n\}, k_1, \dots, k_n)}. \end{aligned}$$

It is not difficult to verify that f is symmetric and multilinear. By the universal mapping property of the symmetric tensor product, the linear map $f_\odot: S^m(E) \rightarrow F$ such that $f = f_\odot \circ \varphi$, is the desired map h . Then by Proposition 33.4, it follows that the family

$$\left(e_{i_1}^{\odot M(i_1)} \odot \cdots \odot e_{i_k}^{\odot M(i_k)} \right)_{\substack{M \in \mathbb{N}^{(I)}, |M|=m, \\ \{i_1, \dots, i_k\} = \text{dom}(M)}}$$

is linearly independent. Using the commutativity of \odot , we can also show that these vectors generate $S^m(E)$, and thus, they form a basis for $S^m(E)$.

If I is infinite dimensional, then for any m vectors $v_1, \dots, v_m \in F$ there is a finite subset J of I such that $v_k = \sum_{j \in J} u_{j,k} e_j$ for $k = 1, \dots, m$, and if we write $n = |J|$, then the formula for $f(v_1, \dots, v_m)$ is obtained by replacing the set $\{1, \dots, n\}$ by J . The details are left as an exercise. \square

As a consequence, when I is finite, say of size $p = \dim(E)$, the dimension of $S^m(E)$ is the number of finite multisets (j_1, \dots, j_p) , such that $j_1 + \dots + j_p = m$, $j_k \geq 0$. We leave as an exercise to show that this number is $\binom{p+m-1}{m}$. Thus, if $\dim(E) = p$, then the dimension of $S^m(E)$ is $\binom{p+m-1}{m}$. Compare with the dimension of $E^{\otimes m}$, which is p^m . In particular, when $p = 2$, the dimension of $S^m(E)$ is $m + 1$. This can also be seen directly.

Remark: The number $\binom{p+m-1}{m}$ is also the number of homogeneous monomials

$$X_1^{j_1} \cdots X_p^{j_p}$$

of total degree m in p variables (we have $j_1 + \dots + j_p = m$). This is not a coincidence! Given a vector space E and a basis $(e_i)_{i \in I}$ for E , Proposition 33.28 shows that every symmetric tensor $z \in S^m(E)$ can be written in a unique way as

$$z = \sum_{\substack{M \in \mathbb{N}^{(I)} \\ \sum_{i \in I} M(i) = m \\ \{i_1, \dots, i_k\} = \text{dom}(M)}} \lambda_M e_{i_1}^{\odot M(i_1)} \odot \cdots \odot e_{i_k}^{\odot M(i_k)},$$

for some unique family of scalars $\lambda_M \in K$, all zero except for a finite number.

This looks like a homogeneous polynomial of total degree m , where the monomials of total degree m are the symmetric tensors

$$e_{i_1}^{\odot M(i_1)} \odot \cdots \odot e_{i_k}^{\odot M(i_k)}$$

in the “indeterminates” e_i , where $i \in I$ (recall that $M(i_1) + \dots + M(i_k) = m$) and implies that polynomials can be defined in terms of symmetric tensors.

33.9 Some Useful Isomorphisms for Symmetric Powers

We can show the following property of the symmetric tensor product, using the proof technique of Proposition 33.13 (3).

Proposition 33.29. *We have the following isomorphism:*

$$S^n(E \oplus F) \cong \bigoplus_{k=0}^n S^k(E) \otimes S^{n-k}(F).$$

33.10 Duality for Symmetric Powers

In this section all vector spaces are assumed to have *finite dimension over a field of characteristic zero*. We define a nondegenerate pairing $S^n(E^*) \times S^n(E) \rightarrow K$ as follows: Consider the multilinear map

$$(E^*)^n \times E^n \rightarrow K$$

given by

$$(v_1^*, \dots, v_n^*, u_1, \dots, u_n) \mapsto \sum_{\sigma \in \mathfrak{S}_n} v_{\sigma(1)}^*(u_1) \cdots v_{\sigma(n)}^*(u_n).$$

Note that the expression on the right-hand side is “almost” the determinant $\det(v_j^*(u_i))$, except that the sign $\text{sgn}(\sigma)$ is missing (where $\text{sgn}(\sigma)$ is the signature of the permutation σ ; that is, the parity of the number of transpositions into which σ can be factored). Such an expression is called a *permanent*.

It can be verified that this expression is symmetric w.r.t. the u_i 's and also w.r.t. the v_j^* . For any fixed $(v_1^*, \dots, v_n^*) \in (E^*)^n$, we get a symmetric multilinear map

$$l_{v_1^*, \dots, v_n^*}: (u_1, \dots, u_n) \mapsto \sum_{\sigma \in \mathfrak{S}_n} v_{\sigma(1)}^*(u_1) \cdots v_{\sigma(n)}^*(u_n)$$

from E^n to K . The map $l_{v_1^*, \dots, v_n^*}$ extends uniquely to a linear map $L_{v_1^*, \dots, v_n^*}: S^n(E) \rightarrow K$ making the following diagram commute:

$$\begin{array}{ccc} E^n & \xrightarrow{\iota \odot} & S^n(E) \\ l_{v_1^*, \dots, v_n^*} \searrow & & \downarrow L_{v_1^*, \dots, v_n^*} \\ & & K. \end{array}$$

We also have the symmetric multilinear map

$$(v_1^*, \dots, v_n^*) \mapsto L_{v_1^*, \dots, v_n^*}$$

from $(E^*)^n$ to $\text{Hom}(S^n(E), K)$, which extends to a linear map L from $S^n(E^*)$ to $\text{Hom}(S^n(E), K)$ making the following diagram commute:

$$\begin{array}{ccc} (E^*)^n & \xrightarrow{\iota \odot^*} & S^n(E^*) \\ \searrow & & \downarrow L \\ & & \text{Hom}(S^n(E), K). \end{array}$$

However, in view of the isomorphism

$$\text{Hom}(U \otimes V, W) \cong \text{Hom}(U, \text{Hom}(V, W)),$$

with $U = S^n(E^*)$, $V = S^n(E)$ and $W = K$, we can view L as a linear map

$$L: S^n(E^*) \otimes S^n(E) \longrightarrow K,$$

which by Proposition 33.8 corresponds to a bilinear map

$$\langle -, - \rangle: S^n(E^*) \times S^n(E) \longrightarrow K. \quad (*)$$

This pairing is given explicitly on generators by

$$\langle v_1^* \odot \cdots \odot v_n^*, u_1, \dots, u_n \rangle = \sum_{\sigma \in \mathfrak{S}_n} v_{\sigma(1)}^*(u_1) \cdots v_{\sigma(n)}^*(u_n).$$

Now this pairing is nondegenerate. This can be shown using bases.² If (e_1, \dots, e_m) is a basis of E , then for every basis element $(e_{i_1}^*)^{\odot n_1} \odot \cdots \odot (e_{i_k}^*)^{\odot n_k}$ of $S^n(E^*)$, with $n_1 + \cdots + n_k = n$, we have

$$\langle (e_{i_1}^*)^{\odot n_1} \odot \cdots \odot (e_{i_k}^*)^{\odot n_k}, e_{i_1}^{\odot n_1} \odot \cdots \odot e_{i_k}^{\odot n_k} \rangle = n_1! \cdots n_k!,$$

and

$$\langle (e_{i_1}^*)^{\odot n_1} \odot \cdots \odot (e_{i_k}^*)^{\odot n_k}, e_{j_1} \odot \cdots \odot e_{j_n} \rangle = 0$$

if $(j_1, \dots, j_n) \neq (\underbrace{i_1, \dots, i_1}_{n_1}, \dots, \underbrace{i_k, \dots, i_k}_{n_k})$.

If the field K has characteristic zero, then $n_1! \cdots n_k! \neq 0$. We leave the details as an exercise to the reader. Therefore we get a canonical isomorphism

$$(S^n(E))^* \cong S^n(E^*).$$

The following proposition summarizes the duality properties of symmetric powers.

Proposition 33.30. *Assume the field K has characteristic zero. We have the canonical isomorphisms*

$$(S^n(E))^* \cong S^n(E^*)$$

and

$$S^n(E^*) \cong \text{Sym}^n(E; K) = \text{Hom}_{\text{symlin}}(E^n, K),$$

which allows us to interpret symmetric tensors over E^* as symmetric multilinear maps.

Proof. The isomorphism

$$\mu: S^n(E^*) \cong \text{Sym}^n(E; K)$$

follows from the isomorphisms $(S^n(E))^* \cong S^n(E^*)$ and $(S^n(E))^* \cong \text{Sym}^n(E; K)$ given by Proposition 33.26. \square

Remarks:

1. The isomorphism $\mu: S^n(E^*) \cong \text{Sym}^n(E; K)$ discussed above can be described explicitly as the linear extension of the map given by

$$\mu(v_1^* \odot \cdots \odot v_n^*)(u_1, \dots, u_n) = \sum_{\sigma \in \mathfrak{S}_n} v_{\sigma(1)}^*(u_1) \cdots v_{\sigma(n)}^*(u_n).$$

²This is where the assumption that we are in finite dimension and that the field has characteristic zero are used.

If (e_1, \dots, e_m) is a basis of E , then for every basis element $(e_{i_1}^*)^{\odot n_1} \odot \cdots \odot (e_{i_k}^*)^{\odot n_k}$ of $S^n(E^*)$, with $n_1 + \cdots + n_k = n$, we have

$$\mu((e_{i_1}^*)^{\odot n_1} \odot \cdots \odot (e_{i_k}^*)^{\odot n_k})(\underbrace{e_{i_1}, \dots, e_{i_1}}_{n_1}, \dots, \underbrace{e_{i_k}, \dots, e_{i_k}}_{n_k}) = n_1! \cdots n_k!,$$

If the field K has positive characteristic, then it is possible that $n_1! \cdots n_k! = 0$, and this is why we required K to be of characteristic 0 in order for Proposition 33.30 to hold.

2. The canonical isomorphism of Proposition 33.30 holds under more general conditions. Namely, that K is a commutative algebra with identity over \mathbb{Q} , and that the E is a finitely-generated projective K -module (see Definition 35.7). See Bourbaki, [25] (Chapter III, §11, Section 5, Proposition 8).

The map from E^n to $S^n(E)$ given by $(u_1, \dots, u_n) \mapsto u_1 \odot \cdots \odot u_n$ yields a surjection $\pi: E^{\otimes n} \rightarrow S^n(E)$. Because we are dealing with vector spaces, this map has some section; that is, there is some injection $\eta: S^n(E) \rightarrow E^{\otimes n}$ with $\pi \circ \eta = \text{id}$. Since our field K has characteristic 0, there is a special section having a natural definition involving a symmetrization process defined as follows: For every permutation σ , we have the map $r_\sigma: E^n \rightarrow E^{\otimes n}$ given by

$$r_\sigma(u_1, \dots, u_n) = u_{\sigma(1)} \otimes \cdots \otimes u_{\sigma(n)}.$$

As r_σ is clearly multilinear, r_σ extends to a linear map $(r_\sigma)_\otimes: E^{\otimes n} \rightarrow E^{\otimes n}$ making the following diagram commute

$$\begin{array}{ccc} E^n & \xrightarrow{\iota_\otimes} & E^{\otimes n} \\ & \searrow r_\sigma & \downarrow (r_\sigma)_\otimes \\ & & E^{\otimes n}, \end{array}$$

and we get a map $\mathfrak{S}_n \times E^{\otimes n} \longrightarrow E^{\otimes n}$, namely

$$\sigma \cdot z = (r_\sigma)_\otimes(z).$$

It is immediately checked that this is a left action of the symmetric group \mathfrak{S}_n on $E^{\otimes n}$, and the tensors $z \in E^{\otimes n}$ such that

$$\sigma \cdot z = z, \quad \text{for all } \sigma \in \mathfrak{S}_n$$

are called *symmetrized* tensors.

We define the map $\eta: E^n \rightarrow E^{\otimes n}$ by

$$\eta(u_1, \dots, u_n) = \frac{1}{n!} \sum_{\sigma \in \mathfrak{S}_n} \sigma \cdot (u_1 \otimes \cdots \otimes u_n) = \frac{1}{n!} \sum_{\sigma \in \mathfrak{S}_n} u_{\sigma(1)} \otimes \cdots \otimes u_{\sigma(n)}.$$

As the right hand side is clearly symmetric, we get a linear map $\eta_{\odot}: S^n(E) \rightarrow E^{\otimes n}$ making the following diagram commute.

$$\begin{array}{ccc} E^n & \xrightarrow{\iota_{\odot}} & S^n(E) \\ \eta \searrow & & \downarrow \eta_{\odot} \\ & & E^{\otimes n} \end{array}$$

Clearly, $\eta_{\odot}(S^n(E))$ is the set of symmetrized tensors in $E^{\otimes n}$. If we consider the map $S = \eta_{\odot} \circ \pi: E^{\otimes n} \rightarrow E^{\otimes n}$ where π is the surjection $\pi: E^{\otimes n} \rightarrow S^n(E)$, it is easy to check that $S \circ S = S$. Therefore, S is a projection, and by linear algebra, we know that

$$E^{\otimes n} = S(E^{\otimes n}) \oplus \text{Ker } S = \eta_{\odot}(S^n(E)) \oplus \text{Ker } S.$$

It turns out that $\text{Ker } S = E^{\otimes n} \cap \mathfrak{I} = \text{Ker } \pi$, where \mathfrak{I} is the two-sided ideal of $T(E)$ generated by all tensors of the form $u \otimes v - v \otimes u \in E^{\otimes 2}$ (for example, see Knapp [104], Appendix A). Therefore, η_{\odot} is injective,

$$E^{\otimes n} = \eta_{\odot}(S^n(E)) \oplus (E^{\otimes n} \cap \mathfrak{I}) = \eta_{\odot}(S^n(E)) \oplus \text{Ker } \pi,$$

and the symmetric tensor power $S^n(E)$ is naturally embedded into $E^{\otimes n}$.

33.11 Symmetric Algebras

As in the case of tensors, we can pack together all the symmetric powers $S^n(V)$ into an algebra.

Definition 33.20. Given a vector space V , the space

$$S(V) = \bigoplus_{m \geq 0} S^m(V),$$

is called the *symmetric tensor algebra of V* .

We could adapt what we did in Section 33.6 for general tensor powers to symmetric tensors but since we already have the algebra $T(V)$, we can proceed faster. If \mathfrak{I} is the two-sided ideal generated by all tensors of the form $u \otimes v - v \otimes u \in V^{\otimes 2}$, we set

$$S^\bullet(V) = T(V)/\mathfrak{I}.$$

Observe that since the ideal \mathfrak{I} is generated by elements in $V^{\otimes 2}$, every tensor in \mathfrak{I} is a linear combination of tensors of the form $\omega_1 \otimes (u \otimes v - v \otimes u) \otimes \omega_2$, with $\omega_1 \in V^{\otimes n_1}$ and $\omega_2 \in V^{\otimes n_2}$ for some $n_1, n_2 \in \mathbb{N}$, which implies that

$$\mathfrak{I} = \bigoplus_{m \geq 0} (\mathfrak{I} \cap V^{\otimes m}).$$

Then, $S^\bullet(V)$ automatically inherits a multiplication operation which is commutative, and since $T(V)$ is graded, that is

$$T(V) = \bigoplus_{m \geq 0} V^{\otimes m},$$

we have

$$S^\bullet(V) = \bigoplus_{m \geq 0} V^{\otimes m} / (\mathfrak{J} \cap V^{\otimes m}).$$

However, it is easy to check that

$$S^m(V) \cong V^{\otimes m} / (\mathfrak{J} \cap V^{\otimes m}),$$

so

$$S^\bullet(V) \cong S(V).$$

When V is of finite dimension n , $S(V)$ corresponds to *the algebra of polynomials with coefficients in K in n variables* (this can be seen from Proposition 33.28). When V is of infinite dimension and $(u_i)_{i \in I}$ is a basis of V , the algebra $S(V)$ corresponds to the algebra of polynomials in infinitely many variables in I . What's nice about the symmetric tensor algebra $S(V)$ is that it provides an intrinsic definition of a polynomial algebra in any set of I variables.

It is also easy to see that $S(V)$ satisfies the following universal mapping property.

Proposition 33.31. *Given any commutative K -algebra A , for any linear map $f: V \rightarrow A$, there is a unique K -algebra homomorphism $\bar{f}: S(V) \rightarrow A$ so that*

$$f = \bar{f} \circ i,$$

as in the diagram below.

$$\begin{array}{ccc} V & \xrightarrow{i} & S(V) \\ & \searrow f & \downarrow \bar{f} \\ & & A \end{array}$$

Remark: If E is finite-dimensional, recall the isomorphism $\mu: S^n(E^*) \rightarrow \text{Sym}^n(E; K)$ defined as the linear extension of the map given by

$$\mu(v_1^* \odot \cdots \odot v_n^*)(u_1, \dots, u_n) = \sum_{\sigma \in \mathfrak{S}_n} v_{\sigma(1)}^*(u_1) \cdots v_{\sigma(n)}^*(u_n).$$

Now we have also a multiplication operation $S^m(E^*) \times S^n(E^*) \rightarrow S^{m+n}(E^*)$. The following question then arises:

Can we define a multiplication $\text{Sym}^m(E; K) \times \text{Sym}^n(E; K) \rightarrow \text{Sym}^{m+n}(E; K)$ directly on symmetric multilinear forms, so that the following diagram commutes?

$$\begin{array}{ccc} \text{S}^m(E^*) \times \text{S}^n(E^*) & \xrightarrow{\odot} & \text{S}^{m+n}(E^*) \\ \downarrow \mu_m \times \mu_n & & \downarrow \mu_{m+n} \\ \text{Sym}^m(E; K) \times \text{Sym}^n(E; K) & \xrightarrow{\cdot} & \text{Sym}^{m+n}(E; K) \end{array}$$

The answer is *yes!* The solution is to define this multiplication such that for $f \in \text{Sym}^m(E; K)$ and $g \in \text{Sym}^n(E; K)$,

$$(f \cdot g)(u_1, \dots, u_{m+n}) = \sum_{\sigma \in \text{shuffle}(m, n)} f(u_{\sigma(1)}, \dots, u_{\sigma(m)})g(u_{\sigma(m+1)}, \dots, u_{\sigma(m+n)}), \quad (*)$$

where $\text{shuffle}(m, n)$ consists of all (m, n) -“shuffles;” that is, permutations σ of $\{1, \dots, m+n\}$ such that $\sigma(1) < \dots < \sigma(m)$ and $\sigma(m+1) < \dots < \sigma(m+n)$. Observe that a (m, n) -shuffle is completely determined by the sequence $\sigma(1) < \dots < \sigma(m)$.

For example, suppose $m = 2$ and $n = 1$. Given $v_1^*, v_2^*, v_3^* \in E^*$, the multiplication structure on $\text{S}(E^*)$ implies that $(v_1^* \odot v_2^*) \cdot v_3^* = v_1^* \odot v_2^* \odot v_3^* \in \text{S}^3(E^*)$. Furthermore, for $u_1, u_2, u_3 \in E$,

$$\begin{aligned} \mu_3(v_1^* \odot v_2^* \odot v_3^*)(u_1, u_2, u_3) &= \sum_{\sigma \in \mathfrak{S}_3} v_{\sigma(1)}^*(u_1)v_{\sigma(2)}^*(u_2)v_{\sigma(3)}^*(u_3) \\ &= v_1^*(u_1)v_2^*(u_2)v_3^*(u_3) + v_1^*(u_1)v_3^*(u_2)v_2^*(u_3) \\ &\quad + v_2^*(u_1)v_1^*(u_2)v_3^*(u_3) + v_2^*(u_1)v_3^*(u_2)v_1^*(u_3) \\ &\quad + v_3^*(u_1)v_1^*(u_2)v_2^*(u_3) + v_3^*(u_1)v_2^*(u_2)v_1^*(u_3). \end{aligned}$$

Now the $(2, 1)$ - shuffles of $\{1, 2, 3\}$ are the following three permutations, namely

$$\begin{pmatrix} 1 & 2 & 3 \\ 1 & 2 & 3 \end{pmatrix}, \quad \begin{pmatrix} 1 & 2 & 3 \\ 1 & 3 & 2 \end{pmatrix}, \quad \begin{pmatrix} 1 & 2 & 3 \\ 2 & 3 & 1 \end{pmatrix}.$$

If $f \cong \mu_2(v_1^* \odot v_2^*)$ and $g \cong \mu_1(v_3^*)$, then $(*)$ implies that

$$\begin{aligned} (f \cdot g)(u_1, u_2, u_3) &= \sum_{\sigma \in \text{shuffle}(2, 1)} f(u_{\sigma(1)}, u_{\sigma(2)})g(u_{\sigma(3)}) \\ &= f(u_1, u_2)g(u_3) + f(u_1, u_3)g(u_2) + f(u_2, u_3)g(u_1) \\ &= \mu_2(v_1^* \odot v_2^*)(u_1, u_2)\mu_1(v_3^*)(u_3) + \mu_2(v_1^* \odot v_2^*)(u_1, u_3)\mu_1(v_3^*)(u_2) \\ &\quad + \mu_2(v_1^* \odot v_2^*)(u_2, u_3)\mu_1(v_3^*)(u_1) \\ &= (v_1^*(u_1)v_2^*(u_2) + v_2^*(u_1)v_1^*(u_2))v_3^*(u_3) \\ &\quad + (v_1^*(u_1)v_2^*(u_3) + v_2^*(u_1)v_1^*(u_3))v_3^*(u_2) \\ &\quad + (v_1^*(u_2)v_2^*(u_3) + v_2^*(u_2)v_1^*(u_3))v_3^*(u_1) \\ &= \mu_3(v_1^* \odot v_2^* \odot v_3^*)(u_1, u_2, u_3). \end{aligned}$$

We leave it as an exercise for the reader to verify Equation (*) for arbitrary nonnegative integers m and n .

Another useful canonical isomorphism (of K -algebras) is given below.

Proposition 33.32. *For any two vector spaces E and F , there is a canonical isomorphism (of K -algebras)*

$$\mathrm{S}(E \oplus F) \cong \mathrm{S}(E) \otimes \mathrm{S}(F).$$

33.12 Problems

Problem 33.1. Prove Proposition 33.4.

Problem 33.2. Given two linear maps $f: E \rightarrow E'$ and $g: F \rightarrow F'$, we defined the unique linear map

$$f \otimes g: E \otimes F \rightarrow E' \otimes F'$$

by

$$(f \otimes g)(u \otimes v) = f(u) \otimes g(v),$$

for all $u \in E$ and all $v \in F$. See Proposition 33.9. Thus $f \otimes g \in \mathrm{Hom}(E \otimes F, E' \otimes F')$. If we denote the tensor product $E \otimes F$ by $T(E, F)$, and we assume that E, E' and F, F' are finite dimensional, pick bases and show that the map induced by $f \otimes g \mapsto T(f, g)$ is an isomorphism

$$\mathrm{Hom}(E, F) \otimes \mathrm{Hom}(E', F') \cong \mathrm{Hom}(E \otimes F, E' \otimes F').$$

Problem 33.3. Adjust the proof of Proposition 33.13 (2) to show that

$$E \otimes (F \otimes G) \cong E \otimes F \otimes G,$$

whenever E , F , and G are arbitrary vector spaces.

Problem 33.4. Given a fixed vector space G , for any two vector spaces M and N and every linear map $f: M \rightarrow N$, we defined $\tau_G(f) = f \otimes \mathrm{id}_G$ to be the unique linear map making the following diagram commute.

$$\begin{array}{ccc} M \times G & \xrightarrow{\iota_M \otimes} & M \otimes G \\ f \times \mathrm{id}_G \downarrow & & \downarrow f \otimes \mathrm{id}_G \\ N \times G & \xrightarrow{\iota_N \otimes} & N \otimes G \end{array}$$

See the proof of Proposition 33.13 (3). Show that

$$(1) \quad \tau_G(0) = 0,$$

$$(2) \quad \tau_G(\mathrm{id}_M) = (\mathrm{id}_M \otimes \mathrm{id}_G) = \mathrm{id}_{M \otimes G},$$

$$(3) \quad \text{If } f': M \rightarrow N \text{ is another linear map, then } \tau_G(f + f') = \tau_G(f) + \tau_G(f').$$

Problem 33.5. Induct on $m \geq 2$ to prove the canonical isomorphism

$$V^{\otimes m} \otimes V^{\otimes n} \cong V^{\otimes(m+n)}.$$

Use this isomorphism to show that $\cdot: V^{\otimes m} \times V^{\otimes n} \rightarrow V^{\otimes(m+n)}$ defined as

$$(v_1 \otimes \cdots \otimes v_m) \cdot (w_1 \otimes \cdots \otimes w_n) = v_1 \otimes \cdots \otimes v_m \otimes w_1 \otimes \cdots \otimes w_n.$$

induces a multiplication on $T(V)$.

Hint. See Jacobson [99], Section 3.9, or Bertin [15], Chapter 4, Section 2.).

Problem 33.6. Prove Proposition 33.19.

Hint. See Knapp [104] (Appendix A, Proposition A.14) or Bertin [15] (Chapter 4, Theorem 2.4).

Problem 33.7. Given linear maps $f: E \rightarrow E'$ and $f': E' \rightarrow E''$, show that

$$(f' \circ f) \odot (f' \circ f) = (f' \odot f') \circ (f \odot f).$$

Problem 33.8. Complete the proof of Proposition 33.28 for the case of an infinite dimensional vector space E .

Problem 33.9. Let I be a finite index set of cardinality p . Let m be a nonnegative integer. Show that the number of multisets over I with cardinality m is $\binom{p+m-1}{m}$.

Problem 33.10. Prove Proposition 33.29.

Problem 33.11. Using bases, show that the bilinear map at $(*)$ in Section 33.10 produces a nondegenerate pairing.

Problem 33.12. Let \mathfrak{I} be the two-sided ideal generated by all tensors of the form $u \otimes v - v \otimes u \in V^{\otimes 2}$. Prove that $S^m(V) \cong V^{\otimes m}/(\mathfrak{I} \cap V^{\otimes m})$.

Problem 33.13. Verify Equation $(*)$ of Section 33.11 for arbitrary nonnegative integers m and n .

Chapter 34

Exterior Tensor Powers and Exterior Algebras

34.1 Exterior Tensor Powers

In this chapter we consider *alternating* (also called *skew-symmetric*) multilinear maps and *exterior tensor powers* (also called *alternating tensor powers*), denoted $\Lambda^n(E)$. In many respects alternating multilinear maps and exterior tensor powers can be treated much like symmetric tensor powers, except that $\text{sgn}(\sigma)$ needs to be inserted in front of the formulae valid for symmetric powers.

Roughly speaking, we are now in the world of determinants rather than in the world of permanents. However, there are also some fundamental differences, one of which being that the exterior tensor power $\Lambda^n(E)$ is the trivial vector space (0) when E is finite-dimensional and when $n > \dim(E)$. This chapter provides the firm foundations for understanding differential forms.

As in the case of symmetric tensor powers, since we already have the tensor algebra $T(V)$, we can proceed rather quickly. But first let us review some basic definitions and facts.

Definition 34.1. Let $f: E^n \rightarrow F$ be a multilinear map. We say that f *alternating* iff for all $u_i \in E$, $f(u_1, \dots, u_n) = 0$ whenever $u_i = u_{i+1}$, for some i with $1 \leq i \leq n-1$; that is, $f(u_1, \dots, u_n) = 0$ whenever two adjacent arguments are identical. We say that f is *skew-symmetric* (or *anti-symmetric*) iff

$$f(u_{\sigma(1)}, \dots, u_{\sigma(n)}) = \text{sgn}(\sigma)f(u_1, \dots, u_n),$$

for every permutation $\sigma \in \mathfrak{S}_n$, and all $u_i \in E$.

For $n = 1$, we agree that every linear map $f: E \rightarrow F$ is alternating. The vector space of all multilinear alternating maps $f: E^n \rightarrow F$ is denoted $\text{Alt}^n(E; F)$. Note that $\text{Alt}^1(E; F) = \text{Hom}(E, F)$. The following basic proposition shows the relationship between alternation and skew-symmetry.

Proposition 34.1. *Let $f: E^n \rightarrow F$ be a multilinear map. If f is alternating, then the following properties hold:*

(1) *For all i , with $1 \leq i \leq n - 1$,*

$$f(\dots, u_i, u_{i+1}, \dots) = -f(\dots, u_{i+1}, u_i, \dots).$$

(2) *For every permutation $\sigma \in \mathfrak{S}_n$,*

$$f(u_{\sigma(1)}, \dots, u_{\sigma(n)}) = \text{sgn}(\sigma)f(u_1, \dots, u_n).$$

(3) *For all i, j , with $1 \leq i < j \leq n$,*

$$f(\dots, u_i, \dots, u_j, \dots) = 0 \quad \text{whenever } u_i = u_j.$$

Moreover, if our field K has characteristic different from 2, then every skew-symmetric multilinear map is alternating.

Proof. (1) By multilinearity applied twice, we have

$$\begin{aligned} f(\dots, u_i + u_{i+1}, u_i + u_{i+1}, \dots) &= f(\dots, u_i, u_i, \dots) + f(\dots, u_i, u_{i+1}, \dots) \\ &\quad + f(\dots, u_{i+1}, u_i, \dots) + f(\dots, u_{i+1}, u_{i+1}, \dots). \end{aligned}$$

Since f is alternating, we get

$$0 = f(\dots, u_i, u_{i+1}, \dots) + f(\dots, u_{i+1}, u_i, \dots);$$

that is, $f(\dots, u_i, u_{i+1}, \dots) = -f(\dots, u_{i+1}, u_i, \dots)$.

(2) Clearly, the symmetric group, \mathfrak{S}_n , acts on $\text{Alt}^n(E; F)$ on the left, via

$$\sigma \cdot f(u_1, \dots, u_n) = f(u_{\sigma(1)}, \dots, u_{\sigma(n)}).$$

Consequently, as \mathfrak{S}_n is generated by the transpositions (permutations that swap exactly two elements), since for a transposition, (2) is simply (1), we deduce (2) by induction on the number of transpositions in σ .

(3) There is a permutation σ that sends u_i and u_j respectively to u_1 and u_2 . By hypothesis $u_i = u_j$, so we have $u_{\sigma(1)} = u_{\sigma(2)}$, and as f is alternating we have

$$f(u_{\sigma(1)}, \dots, u_{\sigma(n)}) = 0.$$

However, by (2),

$$f(u_1, \dots, u_n) = \text{sgn}(\sigma)f(u_{\sigma(1)}, \dots, u_{\sigma(n)}) = 0.$$

Now when f is skew-symmetric, if σ is the transposition swapping u_i and $u_{i+1} = u_i$, as $\text{sgn}(\sigma) = -1$, we get

$$f(\dots, u_i, u_i, \dots) = -f(\dots, u_i, u_i, \dots),$$

so that

$$2f(\dots, u_i, u_i, \dots) = 0,$$

and in every characteristic except 2, we conclude that $f(\dots, u_i, u_i, \dots) = 0$, namely f is alternating. \square

Proposition 34.1 shows that in every characteristic except 2, alternating and skew-symmetric multilinear maps are identical. Using Proposition 34.1 we easily deduce the following crucial fact.

Proposition 34.2. *Let $f: E^n \rightarrow F$ be an alternating multilinear map. For any families of vectors, (u_1, \dots, u_n) and (v_1, \dots, v_n) , with $u_i, v_i \in E$, if*

$$v_j = \sum_{i=1}^n a_{ij} u_i, \quad 1 \leq j \leq n,$$

then

$$f(v_1, \dots, v_n) = \left(\sum_{\sigma \in \mathfrak{S}_n} \operatorname{sgn}(\sigma) a_{\sigma(1),1} \cdots a_{\sigma(n),n} \right) f(u_1, \dots, u_n) = \det(A) f(u_1, \dots, u_n),$$

where A is the $n \times n$ matrix, $A = (a_{ij})$.

Proof. Use Property (ii) of Proposition 34.1. \square

We are now ready to define and construct exterior tensor powers.

Definition 34.2. An n -th exterior tensor power of a vector space E , where $n \geq 1$, is a vector space A together with an alternating multilinear map $\varphi: E^n \rightarrow A$, such that for every vector space F and for every alternating multilinear map $f: E^n \rightarrow F$, there is a unique linear map $f_\wedge: A \rightarrow F$ with

$$f(u_1, \dots, u_n) = f_\wedge(\varphi(u_1, \dots, u_n)),$$

for all $u_1, \dots, u_n \in E$, or for short

$$f = f_\wedge \circ \varphi.$$

Equivalently, there is a unique linear map f_\wedge such that the following diagram commutes:

$$\begin{array}{ccc} E^n & \xrightarrow{\varphi} & A \\ & \searrow f & \downarrow f_\wedge \\ & & F. \end{array}$$

The above property is called the *universal mapping property* of the exterior tensor power (A, φ) .

We now show that any two n -th exterior tensor powers (A_1, φ_1) and (A_2, φ_2) for E are isomorphic.

Proposition 34.3. *Given any two n -th exterior tensor powers (A_1, φ_1) and (A_2, φ_2) for E , there is an isomorphism $h: A_1 \rightarrow A_2$ such that*

$$\varphi_2 = h \circ \varphi_1.$$

Proof. Replace tensor product by n -th exterior tensor power in the proof of Proposition 33.5. \square

We next give a construction that produces an n -th exterior tensor power of a vector space E .

Theorem 34.4. *Given a vector space E , an n -th exterior tensor power $(\bigwedge^n(E), \varphi)$ for E can be constructed ($n \geq 1$). Furthermore, denoting $\varphi(u_1, \dots, u_n)$ as $u_1 \wedge \dots \wedge u_n$, the exterior tensor power $\bigwedge^n(E)$ is generated by the vectors $u_1 \wedge \dots \wedge u_n$, where $u_1, \dots, u_n \in E$, and for every alternating multilinear map $f: E^n \rightarrow F$, the unique linear map $f_\wedge: \bigwedge^n(E) \rightarrow F$ such that $f = f_\wedge \circ \varphi$ is defined by*

$$f_\wedge(u_1 \wedge \dots \wedge u_n) = f(u_1, \dots, u_n)$$

on the generators $u_1 \wedge \dots \wedge u_n$ of $\bigwedge^n(E)$.

Proof sketch. We can give a quick proof using the tensor algebra $T(E)$. Let \mathfrak{I}_a be the two-sided ideal of $T(E)$ generated by all tensors of the form $u \otimes u \in E^{\otimes 2}$. Then let

$$\bigwedge^n(E) = E^{\otimes n} / (\mathfrak{I}_a \cap E^{\otimes n})$$

and let π be the projection $\pi: E^{\otimes n} \rightarrow \bigwedge^n(E)$. If we let $u_1 \wedge \dots \wedge u_n = \pi(u_1 \otimes \dots \otimes u_n)$, it is easy to check that $(\bigwedge^n(E), \wedge)$ satisfies the conditions of Theorem 34.4. \square

Remark: We can also define

$$\bigwedge(E) = T(E)/\mathfrak{I}_a = \bigoplus_{n \geq 0} \bigwedge^n(E),$$

the *exterior algebra* of E . This is the skew-symmetric counterpart of $S(E)$, and we will study it a little later.

For simplicity of notation, we may write $\bigwedge^n E$ for $\bigwedge^n(E)$. We also abbreviate “exterior tensor power” as “exterior power.” Clearly, $\bigwedge^1(E) \cong E$, and it is convenient to set $\bigwedge^0(E) = K$.

The fact that the map $\varphi: E^n \rightarrow \Lambda^n(E)$ is alternating and multilinear can also be expressed as follows:

$$\begin{aligned} u_1 \wedge \cdots \wedge (u_i + v_i) \wedge \cdots \wedge u_n &= (u_1 \wedge \cdots \wedge u_i \wedge \cdots \wedge u_n) \\ &\quad + (u_1 \wedge \cdots \wedge v_i \wedge \cdots \wedge u_n), \\ u_1 \wedge \cdots \wedge (\lambda u_i) \wedge \cdots \wedge u_n &= \lambda(u_1 \wedge \cdots \wedge u_i \wedge \cdots \wedge u_n), \\ u_{\sigma(1)} \wedge \cdots \wedge u_{\sigma(n)} &= \text{sgn}(\sigma) u_1 \wedge \cdots \wedge u_n, \end{aligned}$$

for all $\sigma \in \mathfrak{S}_n$.

The map φ from E^n to $\Lambda^n(E)$ is often denoted ι_\wedge , so that

$$\iota_\wedge(u_1, \dots, u_n) = u_1 \wedge \cdots \wedge u_n.$$

Theorem 34.4 implies the following result.

Proposition 34.5. *There is a canonical isomorphism*

$$\text{Hom}(\bigwedge^n(E), F) \cong \text{Alt}^n(E; F)$$

between the vector space of linear maps $\text{Hom}(\bigwedge^n(E), F)$ and the vector space of alternating multilinear maps $\text{Alt}^n(E; F)$, given by the linear map $- \circ \varphi$ defined by $\mapsto h \circ \varphi$, with $h \in \text{Hom}(\bigwedge^n(E), F)$. In particular, when $F = K$, we get a canonical isomorphism

$$\left(\bigwedge^n(E) \right)^* \cong \text{Alt}^n(E; K).$$

Definition 34.3. Tensors $\alpha \in \bigwedge^n(E)$ are called *alternating n-tensors* or *alternating tensors of degree n* and we write $\deg(\alpha) = n$. Tensors of the form $u_1 \wedge \cdots \wedge u_n$, where $u_i \in E$, are called *simple (or decomposable) alternating n-tensors*. Those alternating n-tensors that are not simple are often called *compound alternating n-tensors*. Simple tensors $u_1 \wedge \cdots \wedge u_n \in \bigwedge^n(E)$ are also called *n-vectors* and tensors in $\bigwedge^n(E^*)$ are often called *(alternating) n-forms*.

Given a linear map $f: E \rightarrow E'$, since the map $\iota'_\wedge \circ (f \times f)$ is bilinear and alternating, there is a unique linear map $f \wedge f: \bigwedge^2(E) \rightarrow \bigwedge^2(E')$ making the following diagram commute:

$$\begin{array}{ccc} E^2 & \xrightarrow{\iota'_\wedge} & \bigwedge^2(E) \\ f \times f \downarrow & & \downarrow f \wedge f \\ (E')^2 & \xrightarrow{\iota'_\wedge} & \bigwedge^2(E'). \end{array}$$

The map $f \wedge f: \bigwedge^2(E) \rightarrow \bigwedge^2(E')$ is determined by

$$(f \wedge f)(u \wedge v) = f(u) \wedge f(v).$$

Proposition 34.6. *Given any two linear maps $f: E \rightarrow E'$ and $f': E' \rightarrow E''$, we have*

$$(f' \circ f) \wedge (f' \circ f) = (f' \wedge f') \circ (f \wedge f).$$

The generalization to the alternating product $f \wedge \cdots \wedge f$ of $n \geq 3$ copies of the linear map $f: E \rightarrow E'$ is immediate, and left to the reader.

34.2 Bases of Exterior Powers

Definition 34.4. Let E be any vector space. For any basis $(u_i)_{i \in \Sigma}$ for E , we assume that some total ordering \leq on the index set Σ has been chosen. Call the pair $((u_i)_{i \in \Sigma}, \leq)$ an *ordered basis*. Then for any nonempty finite subset $I \subseteq \Sigma$, let

$$u_I = u_{i_1} \wedge \cdots \wedge u_{i_m},$$

where $I = \{i_1, \dots, i_m\}$, with $i_1 < \cdots < i_m$.

Since $\bigwedge^n(E)$ is generated by the tensors of the form $v_1 \wedge \cdots \wedge v_n$, with $v_i \in E$, in view of skew-symmetry, it is clear that the tensors u_I with $|I| = n$ generate $\bigwedge^n(E)$ (where $((u_i)_{i \in \Sigma}, \leq)$ is an ordered basis). Actually they form a basis. To gain an intuitive understanding of this statement, let $m = 2$ and E be a 3-dimensional vector space lexicographically ordered basis $\{e_1, e_2, e_3\}$. We claim that

$$e_1 \wedge e_2, \quad e_1 \wedge e_3, \quad e_2 \wedge e_3$$

form a basis for $\bigwedge^2(E)$ since they not only generate $\bigwedge^2(E)$ but are linearly independent. The linear independence is argued as follows: given any vector space F , if w_{12}, w_{13}, w_{23} are any vectors in F , there is an alternating bilinear map $h: E^2 \rightarrow F$ such that

$$h(e_1, e_2) = w_{12}, \quad h(e_1, e_3) = w_{13}, \quad h(e_2, e_3) = w_{23}.$$

Because h yields a unique linear map $h_\wedge: \bigwedge^2 E \rightarrow F$ such that

$$h_\wedge(e_i \wedge e_j) = w_{ij}, \quad 1 \leq i < j \leq 3,$$

by Proposition 33.4, the vectors

$$e_1 \wedge e_2, \quad e_1 \wedge e_3, \quad e_2 \wedge e_3$$

are linearly independent. This suggests understanding how an alternating bilinear function $f: E^2 \rightarrow F$ is expressed in terms of its values $f(e_i, e_j)$ on the basis vectors (e_1, e_2, e_3) . Using bilinearity and alternation, we obtain

$$\begin{aligned} f(u_1e_1 + u_2e_2 + u_3e_3, v_1e_1 + v_2e_2 + v_3e_3) &= (u_1v_2 - u_2v_1)f(e_1, e_2) + (u_1v_3 - u_3v_1)f(e_1, e_3) \\ &\quad + (u_2v_3 - u_3v_2)f(e_2, e_3). \end{aligned}$$

Therefore, given $w_{12}, w_{13}, w_{23} \in F$, the function h given by

$$\begin{aligned} h(u_1e_1 + u_2e_2 + u_3e_3, v_1e_1 + v_2e_2 + v_3e_3) &= (u_1v_2 - u_2v_1)w_{12} + (u_1v_3 - u_3v_1)w_{13} \\ &\quad + (u_2v_3 - u_3v_2)w_{23} \end{aligned}$$

is clearly bilinear and alternating, and by construction $h(e_i, e_j) = w_{ij}$, with $1 \leq i < j \leq 3$ does the job.

We now prove the assertion that tensors u_I with $|I| = n$ generate $\bigwedge^n(E)$ for arbitrary n .

Proposition 34.7. *Given any vector space E , if E has finite dimension $d = \dim(E)$, then for all $n > d$, the exterior power $\bigwedge^n(E)$ is trivial; that is $\bigwedge^n(E) = (0)$. If $n \leq d$ or if E is infinite dimensional, then for every ordered basis $((u_i)_{i \in \Sigma}, \leq)$, the family (u_I) is basis of $\bigwedge^n(E)$, where I ranges over finite nonempty subsets of Σ of size $|I| = n$.*

Proof. First assume that E has finite dimension $d = \dim(E)$ and that $n > d$. We know that $\bigwedge^n(E)$ is generated by the tensors of the form $v_1 \wedge \cdots \wedge v_n$, with $v_i \in E$. If u_1, \dots, u_d is a basis of E , as every v_i is a linear combination of the u_j , when we expand $v_1 \wedge \cdots \wedge v_n$ using multilinearity, we get a linear combination of the form

$$v_1 \wedge \cdots \wedge v_n = \sum_{(j_1, \dots, j_n)} \lambda_{(j_1, \dots, j_n)} u_{j_1} \wedge \cdots \wedge u_{j_n},$$

where each (j_1, \dots, j_n) is some sequence of integers $j_k \in \{1, \dots, d\}$. As $n > d$, each sequence (j_1, \dots, j_n) must contain two identical elements. By alternation, $u_{j_1} \wedge \cdots \wedge u_{j_n} = 0$, and so $v_1 \wedge \cdots \wedge v_n = 0$. It follows that $\bigwedge^n(E) = (0)$.

Now assume that either $\dim(E) = d$ and $n \leq d$, or that E is infinite dimensional. The argument below shows that the u_I are nonzero and linearly independent. As usual, let $u_i^* \in E^*$ be the linear form given by

$$u_i^*(u_j) = \delta_{ij}.$$

For any nonempty subset $I = \{i_1, \dots, i_n\} \subseteq \Sigma$ with $i_1 < \cdots < i_n$, for any n vectors $v_1, \dots, v_n \in E$, let

$$l_I(v_1, \dots, v_n) = \det(u_{i_j}^*(v_k)) = \begin{vmatrix} u_{i_1}^*(v_1) & \cdots & u_{i_1}^*(v_n) \\ \vdots & \ddots & \vdots \\ u_{i_n}^*(v_1) & \cdots & u_{i_n}^*(v_n) \end{vmatrix}.$$

If we let the n -tuple (v_1, \dots, v_n) vary we obtain a map l_I from E^n to K , and it is easy to check that this map is alternating multilinear. Thus l_I induces a unique linear map $L_I: \bigwedge^n(E) \rightarrow K$ making the following diagram commute.

$$\begin{array}{ccc} E^n & \xrightarrow{\iota \wedge} & \bigwedge^n(E) \\ & \searrow l_I & \downarrow L_I \\ & & K \end{array}$$

Observe that for any nonempty finite subset $J \subseteq \Sigma$ with $|J| = n$, we have

$$L_I(u_J) = \begin{cases} 1 & \text{if } I = J \\ 0 & \text{if } I \neq J. \end{cases}$$

Note that when $\dim(E) = d$ and $n \leq d$, or when E is infinite-dimensional, the forms $u_{i_1}^*, \dots, u_{i_n}^*$ are all distinct, so the above does hold. Since $L_I(u_I) = 1$, we conclude that $u_I \neq 0$. If we have a linear combination

$$\sum_I \lambda_I u_I = 0,$$

where the above sum is finite and involves nonempty finite subset $I \subseteq \Sigma$ with $|I| = n$, for every such I , when we apply L_I we get $\lambda_I = 0$, proving linear independence. \square

As a corollary, if E is finite dimensional, say $\dim(E) = d$, and if $1 \leq n \leq d$, then we have

$$\dim(\bigwedge^n(E)) = \binom{n}{d},$$

and if $n > d$, then $\dim(\bigwedge^n(E)) = 0$.

Remark: When $n = 0$, if we set $u_\emptyset = 1$, then $(u_\emptyset) = (1)$ is a basis of $\bigwedge^0(V) = K$.

It follows from Proposition 34.7 that the family $(u_I)_I$ where $I \subseteq \Sigma$ ranges over finite subsets of Σ is a basis of $\bigwedge(V) = \bigoplus_{n \geq 0} \bigwedge^n(V)$.

As a corollary of Proposition 34.7 we obtain the following useful criterion for linear independence.

Proposition 34.8. *For any vector space E , the vectors $u_1, \dots, u_n \in E$ are linearly independent iff $u_1 \wedge \cdots \wedge u_n \neq 0$.*

Proof. If $u_1 \wedge \cdots \wedge u_n \neq 0$, then u_1, \dots, u_n must be linearly independent. Otherwise, some u_i would be a linear combination of the other u_j 's (with $j \neq i$), and then, as in the proof of Proposition 34.7, $u_1 \wedge \cdots \wedge u_n$ would be a linear combination of wedges in which two vectors are identical, and thus zero.

Conversely, assume that u_1, \dots, u_n are linearly independent. Then we have the linear forms $u_i^* \in E^*$ such that

$$u_i^*(u_j) = \delta_{i,j} \quad 1 \leq i, j \leq n.$$

As in the proof of Proposition 34.7, we have a linear map $L_{u_1, \dots, u_n} : \bigwedge^n(E) \rightarrow K$ given by

$$L_{u_1, \dots, u_n}(v_1 \wedge \cdots \wedge v_n) = \det(u_j^*(v_i)) = \begin{vmatrix} u_1^*(v_1) & \cdots & u_1^*(v_n) \\ \vdots & \ddots & \vdots \\ u_n^*(v_1) & \cdots & u_n^*(v_n) \end{vmatrix},$$

for all $v_1 \wedge \cdots \wedge v_n \in \bigwedge^n(E)$. As $L_{u_1, \dots, u_n}(u_1 \wedge \cdots \wedge u_n) = 1$, we conclude that $u_1 \wedge \cdots \wedge u_n \neq 0$. \square

Proposition 34.8 shows that *geometrically every nonzero wedge $u_1 \wedge \cdots \wedge u_n$ corresponds to some oriented version of an n -dimensional subspace of E .*

34.3 Some Useful Isomorphisms for Exterior Powers

We can show the following property of the exterior tensor product, using the proof technique of Proposition 33.13.

Proposition 34.9. *We have the following isomorphism:*

$$\bigwedge^n(E \oplus F) \cong \bigoplus_{k=0}^n \bigwedge^k(E) \otimes \bigwedge^{n-k}(F).$$

34.4 Duality for Exterior Powers

In this section *all vector spaces are assumed to have finite dimension*. We define a nondegenerate pairing $\bigwedge^n(E^*) \times \bigwedge^n(E) \rightarrow K$ as follows: Consider the multilinear map

$$(E^*)^n \times E^n \rightarrow K$$

given by

$$\begin{aligned} (v_1^*, \dots, v_n^*, u_1, \dots, u_n) &\mapsto \sum_{\sigma \in \mathfrak{S}_n} \text{sgn}(\sigma) v_{\sigma(1)}^*(u_1) \cdots v_{\sigma(n)}^*(u_n) = \det(v_j^*(u_i)) \\ &= \begin{vmatrix} v_1^*(u_1) & \cdots & v_1^*(u_n) \\ \vdots & \ddots & \vdots \\ v_n^*(u_1) & \cdots & v_n^*(u_n) \end{vmatrix}. \end{aligned}$$

It is easily checked that this expression is alternating w.r.t. the u_i 's and also w.r.t. the v_j^* . For any fixed $(v_1^*, \dots, v_n^*) \in (E^*)^n$, we get an alternating multilinear map

$$l_{v_1^*, \dots, v_n^*}: (u_1, \dots, u_n) \mapsto \det(v_j^*(u_i))$$

from E^n to K . The map $l_{v_1^*, \dots, v_n^*}$ extends uniquely to a linear map $L_{v_1^*, \dots, v_n^*}: \bigwedge^n(E) \rightarrow K$ making the following diagram commute:

$$\begin{array}{ccc} E^n & \xrightarrow{\iota \wedge} & \bigwedge^n(E) \\ & \searrow l_{v_1^*, \dots, v_n^*} & \downarrow L_{v_1^*, \dots, v_n^*} \\ & & K. \end{array}$$

We also have the alternating multilinear map

$$(v_1^*, \dots, v_n^*) \mapsto L_{v_1^*, \dots, v_n^*}$$

from $(E^*)^n$ to $\text{Hom}(\bigwedge^n(E), K)$, which extends to a linear map L from $\bigwedge^n(E^*)$ to $\text{Hom}(\bigwedge^n(E), K)$ making the following diagram commute:

$$\begin{array}{ccc} (E^*)^n & \xrightarrow{\iota_{\wedge^*}} & \bigwedge^n(E^*) \\ & \searrow & \downarrow L \\ & & \text{Hom}(\bigwedge^n(E), K). \end{array}$$

However, in view of the isomorphism

$$\text{Hom}(U \otimes V, W) \cong \text{Hom}(U, \text{Hom}(V, W)),$$

with $U = \bigwedge^n(E^*)$, $V = \bigwedge^n(E)$ and $W = K$, we can view L as a linear map

$$L: \bigwedge^n(E^*) \otimes \bigwedge^n(E) \longrightarrow K,$$

which by Proposition 33.8 corresponds to a bilinear map

$$\langle -, - \rangle: \bigwedge^n(E^*) \times \bigwedge^n(E) \longrightarrow K. \quad (*)$$

This pairing is given explicitly in terms of generators by

$$\langle v_1^* \wedge \cdots \wedge v_n^*, u_1, \dots, u_n \rangle = \det(v_j^*(u_i)).$$

Now this pairing is nondegenerate. This can be shown using bases. Given any basis (e_1, \dots, e_m) of E , for every basis element $e_{i_1}^* \wedge \cdots \wedge e_{i_n}^*$ of $\bigwedge^n(E^*)$ (with $1 \leq i_1 < \cdots < i_n \leq m$), we have

$$\langle e_{i_1}^* \wedge \cdots \wedge e_{i_n}^*, e_{j_1}, \dots, e_{j_n} \rangle = \begin{cases} 1 & \text{if } (j_1, \dots, j_n) = (i_1, \dots, i_n) \\ 0 & \text{otherwise.} \end{cases}$$

We leave the details as an exercise to the reader. As a consequence we get the following canonical isomorphisms.

Proposition 34.10. *There is a canonical isomorphism*

$$(\bigwedge^n(E))^* \cong \bigwedge^n(E^*).$$

There is also a canonical isomorphism

$$\mu: \bigwedge^n(E^*) \cong \text{Alt}^n(E; K)$$

which allows us to interpret alternating tensors over E^ as alternating multilinear maps.*

Proof. The second isomorphism follows from the canonical isomorphism $(\Lambda^n(E))^* \cong \Lambda^n(E^*)$ and the canonical isomorphism $(\Lambda^n(E))^* \cong \text{Alt}^n(E; K)$ given by Proposition 34.5. \square

Remarks:

1. The isomorphism $\mu: \Lambda^n(E^*) \cong \text{Alt}^n(E; K)$ discussed above can be described explicitly as the linear extension of the map given by
$$\mu(v_1^* \wedge \cdots \wedge v_n^*)(u_1, \dots, u_n) = \det(v_j^*(u_i)).$$
2. The canonical isomorphism of Proposition 34.10 holds under more general conditions. Namely, that K is a commutative ring with identity and that E is a finitely-generated projective K -module (see Definition 35.7). See Bourbaki, [25] (Chapter III, §11, Section 5, Proposition 7).
3. Variants of our isomorphism μ are found in the literature. For example, there is a version μ' , where

$$\mu' = \frac{1}{n!} \mu,$$

with the factor $\frac{1}{n!}$ added in front of the determinant. Each version has its own merits and inconveniences. Morita [129] uses μ' because it is more convenient than μ when dealing with characteristic classes. On the other hand, μ' may not be defined for a field with positive characteristic, and when using μ' , some extra factor is needed in defining the wedge operation of alternating multilinear forms (see Section 34.5) and for exterior differentiation. The version μ is the one adopted by Warner [186], Knapp [104], Fulton and Harris [68], and Cartan [34, 35].

If $f: E \rightarrow F$ is any linear map, by transposition we get a linear map $f^\top: F^* \rightarrow E^*$ given by

$$f^\top(v^*) = v^* \circ f, \quad v^* \in F^*.$$

Consequently, we have

$$f^\top(v^*)(u) = v^*(f(u)), \quad \text{for all } u \in E \text{ and all } v^* \in F^*.$$

For any $p \geq 1$, the map

$$(u_1, \dots, u_p) \mapsto f(u_1) \wedge \cdots \wedge f(u_p)$$

from E^p to $\Lambda^p F$ is multilinear alternating, so it induces a unique linear map $\Lambda^p f: \Lambda^p E \rightarrow \Lambda^p F$ making the following diagram commute

$$\begin{array}{ccc} E^p & \xrightarrow{\iota_\wedge} & \Lambda^p E \\ & \searrow & \downarrow \Lambda^p f \\ & & \Lambda^p F, \end{array}$$

and defined on generators by

$$\left(\bigwedge^p f\right)(u_1 \wedge \cdots \wedge u_p) = f(u_1) \wedge \cdots \wedge f(u_p).$$

Combining \bigwedge^p and duality, we get a linear map $\bigwedge^p f^\top: \bigwedge^p F^* \rightarrow \bigwedge^p E^*$ defined on generators by

$$\left(\bigwedge^p f^\top\right)(v_1^* \wedge \cdots \wedge v_p^*) = f^\top(v_1^*) \wedge \cdots \wedge f^\top(v_p^*).$$

Proposition 34.11. *If $f: E \rightarrow F$ is any linear map between two finite-dimensional vector spaces E and F , then*

$$\mu\left(\left(\bigwedge^p f^\top\right)(\omega)\right)(u_1, \dots, u_p) = \mu(\omega)(f(u_1), \dots, f(u_p)), \quad \omega \in \bigwedge^p F^*, \quad u_1, \dots, u_p \in E.$$

Proof. It is enough to prove the formula on generators. By definition of μ , we have

$$\begin{aligned} \mu\left(\left(\bigwedge^p f^\top\right)(v_1^* \wedge \cdots \wedge v_p^*)\right)(u_1, \dots, u_p) &= \mu(f^\top(v_1^*) \wedge \cdots \wedge f^\top(v_p^*))(u_1, \dots, u_p) \\ &= \det(f^\top(v_j^*)(u_i)) \\ &= \det(v_j^*(f(u_i))) \\ &= \mu(v_1^* \wedge \cdots \wedge v_p^*)(f(u_1), \dots, f(u_p)), \end{aligned}$$

as claimed. \square

Remark: The map $\bigwedge^p f^\top$ is often denoted f^* , although this is an ambiguous notation since p is dropped. Proposition 34.11 gives us the behavior of $\bigwedge^p f^\top$ under the identification of $\bigwedge^p E^*$ and $\text{Alt}^p(E; K)$ via the isomorphism μ .

As in the case of symmetric powers, the map from E^n to $\bigwedge^n(E)$ given by $(u_1, \dots, u_n) \mapsto u_1 \wedge \cdots \wedge u_n$ yields a surjection $\pi: E^{\otimes n} \rightarrow \bigwedge^n(E)$. Now this map has some section, so there is some injection $\eta: \bigwedge^n(E) \rightarrow E^{\otimes n}$ with $\pi \circ \eta = \text{id}$. As we saw in Proposition 34.10 there is a canonical isomorphism

$$\left(\bigwedge^n(E)\right)^* \cong \bigwedge^n(E^*)$$

for any field K , even of positive characteristic. However, if our field K has characteristic 0, then there is a special section having a natural definition involving an antisymmetrization process.

Recall, from Section 33.10 that we have a left action of the symmetric group \mathfrak{S}_n on $E^{\otimes n}$. The tensors $z \in E^{\otimes n}$ such that

$$\sigma \cdot z = \text{sgn}(\sigma) z, \quad \text{for all } \sigma \in \mathfrak{S}_n$$

are called *antisymmetrized* tensors. We define the map $\eta: E^n \rightarrow E^{\otimes n}$ by

$$\eta(u_1, \dots, u_n) = \frac{1}{n!} \sum_{\sigma \in \mathfrak{S}_n} \text{sgn}(\sigma) u_{\sigma(1)} \otimes \cdots \otimes u_{\sigma(n)}.^1$$

¹It is the division by $n!$ that requires the field to have characteristic zero.

As the right hand side is an alternating map, we get a unique linear map $\Lambda^n \eta: \Lambda^n(E) \rightarrow E^{\otimes n}$ making the following diagram commute.

$$\begin{array}{ccc} E^n & \xrightarrow{\iota \wedge} & \Lambda^n(E) \\ & \searrow \eta & \downarrow \Lambda^n \eta \\ & & E^{\otimes n}. \end{array}$$

Clearly, $\Lambda^n \eta(\Lambda^n(E))$ is the set of antisymmetrized tensors in $E^{\otimes n}$. If we consider the map $A = (\Lambda^n \eta) \circ \pi: E^{\otimes n} \rightarrow E^{\otimes n}$, it is easy to check that $A \circ A = A$. Therefore, A is a projection, and by linear algebra, we know that

$$E^{\otimes n} = A(E^{\otimes n}) \oplus \text{Ker } A = \bigwedge^n \eta(\bigwedge^n(E)) \oplus \text{Ker } A.$$

It turns out that $\text{Ker } A = E^{\otimes n} \cap \mathfrak{I}_a = \text{Ker } \pi$, where \mathfrak{I}_a is the two-sided ideal of $T(E)$ generated by all tensors of the form $u \otimes u \in E^{\otimes 2}$ (for example, see Knapp [104], Appendix A). Therefore, $\Lambda^n \eta$ is injective,

$$E^{\otimes n} = \bigwedge^n \eta(\bigwedge^n(E)) \oplus (E^{\otimes n} \cap \mathfrak{I}_a) = \bigwedge^n \eta(\bigwedge^n(E)) \oplus \text{Ker } \pi,$$

and the exterior tensor power $\Lambda^n(E)$ is naturally embedded into $E^{\otimes n}$.

34.5 Exterior Algebras

As in the case of symmetric tensors, we can pack together all the exterior powers $\Lambda^n(V)$ into an algebra.

Definition 34.5. Given any vector space V , the vector space

$$\bigwedge(V) = \bigoplus_{m \geq 0} \bigwedge^m(V)$$

is called the *exterior algebra (or Grassmann algebra) of V* .

To make $\bigwedge(V)$ into an algebra, we mimic the procedure used for symmetric powers. If \mathfrak{I}_a is the two-sided ideal generated by all tensors of the form $u \otimes u \in V^{\otimes 2}$, we set

$$\bigwedge^\bullet(V) = T(V)/\mathfrak{I}_a.$$

Then $\bigwedge^\bullet(V)$ automatically inherits a multiplication operation, called *wedge product*, and since $T(V)$ is graded, that is

$$T(V) = \bigoplus_{m \geq 0} V^{\otimes m},$$

we have

$$\bigwedge^{\bullet}(V) = \bigoplus_{m \geq 0} V^{\otimes m} / (\mathfrak{I}_a \cap V^{\otimes m}).$$

However, it is easy to check that

$$\bigwedge^m(V) \cong V^{\otimes m} / (\mathfrak{I}_a \cap V^{\otimes m}),$$

so

$$\bigwedge^{\bullet}(V) \cong \bigwedge^m(V).$$

When V has finite dimension d , we actually have a finite direct sum (coproduct)

$$\bigwedge(V) = \bigoplus_{m=0}^d \bigwedge^m(V),$$

and since each $\bigwedge^m(V)$ has dimension $\binom{d}{m}$, we deduce that

$$\dim(\bigwedge(V)) = 2^d = 2^{\dim(V)}.$$

The multiplication, $\wedge: \bigwedge^m(V) \times \bigwedge^n(V) \rightarrow \bigwedge^{m+n}(V)$, is skew-symmetric in the following precise sense:

Proposition 34.12. *For all $\alpha \in \bigwedge^m(V)$ and all $\beta \in \bigwedge^n(V)$, we have*

$$\beta \wedge \alpha = (-1)^{mn} \alpha \wedge \beta.$$

Proof. Since $v \wedge u = -u \wedge v$ for all $u, v \in V$, Proposition 34.12 follows by induction. \square

Since $\alpha \wedge \alpha = 0$ for every *simple* (also called *decomposable*) tensor $\alpha = u_1 \wedge \cdots \wedge u_n$, it seems natural to infer that $\alpha \wedge \alpha = 0$ for *every* tensor $\alpha \in \bigwedge(V)$. If we consider the case where $\dim(V) \leq 3$, we can indeed prove the above assertion. However, if $\dim(V) \geq 4$, the above fact is generally false! For example, when $\dim(V) = 4$, if (u_1, u_2, u_3, u_4) is a basis for V , for $\alpha = u_1 \wedge u_2 + u_3 \wedge u_4$, we check that

$$\alpha \wedge \alpha = 2u_1 \wedge u_2 \wedge u_3 \wedge u_4,$$

which is nonzero. However, if $\alpha \in \bigwedge^m E$ with m odd, since m^2 is also odd, we have

$$\alpha \wedge \alpha = (-1)^{m^2} \alpha \wedge \alpha = -\alpha \wedge \alpha,$$

so indeed $\alpha \wedge \alpha = 0$ (if K is not a field of characteristic 2).

The above discussion suggests that it might be useful to know when an alternating tensor is simple (decomposable). We will show in Section 34.7 that for tensors $\alpha \in \bigwedge^2(V)$, $\alpha \wedge \alpha = 0$ iff α is simple.

A general criterion for decomposability can be given in terms of some operations known as *left hook* and *right hook* (also called *interior products*); see Section 34.7.

It is easy to see that $\bigwedge(V)$ satisfies the following universal mapping property.

Proposition 34.13. *Given any K -algebra A , for any linear map $f: V \rightarrow A$, if $(f(v))^2 = 0$ for all $v \in V$, then there is a unique K -algebra homomorphism $\bar{f}: \bigwedge(V) \rightarrow A$ so that*

$$f = \bar{f} \circ i,$$

as in the diagram below.

$$\begin{array}{ccc} V & \xrightarrow{i} & \bigwedge(V) \\ & \searrow f & \downarrow \bar{f} \\ & & A \end{array}$$

When E is finite-dimensional, recall the isomorphism $\mu: \bigwedge^n(E^*) \rightarrow \text{Alt}^n(E; K)$, defined as the linear extension of the map given by

$$\mu(v_1^* \wedge \cdots \wedge v_n^*)(u_1, \dots, u_n) = \det(v_j^*(u_i)).$$

Now, we have also a multiplication operation $\bigwedge^m(E^*) \times \bigwedge^n(E^*) \rightarrow \bigwedge^{m+n}(E^*)$. The following question then arises:

Can we define a multiplication $\text{Alt}^m(E; K) \times \text{Alt}^n(E; K) \rightarrow \text{Alt}^{m+n}(E; K)$ directly on alternating multilinear forms, so that the following diagram commutes?

$$\begin{array}{ccc} \bigwedge^m(E^*) \times \bigwedge^n(E^*) & \xrightarrow{\wedge} & \bigwedge^{m+n}(E^*) \\ \downarrow \mu_m \times \mu_n & & \downarrow \mu_{m+n} \\ \text{Alt}^m(E; K) \times \text{Alt}^n(E; K) & \xrightarrow{\wedge} & \text{Alt}^{m+n}(E; K) \end{array}$$

As in the symmetric case, the answer is *yes!* The solution is to define this multiplication such that, for $f \in \text{Alt}^m(E; K)$ and $g \in \text{Alt}^n(E; K)$,

$$(f \wedge g)(u_1, \dots, u_{m+n}) = \sum_{\sigma \in \text{shuffle}(m, n)} \text{sgn}(\sigma) f(u_{\sigma(1)}, \dots, u_{\sigma(m)}) g(u_{\sigma(m+1)}, \dots, u_{\sigma(m+n)}), \quad (**)$$

where $\text{shuffle}(m, n)$ consists of all (m, n) -“shuffles;” that is, permutations σ of $\{1, \dots, m+n\}$ such that $\sigma(1) < \cdots < \sigma(m)$ and $\sigma(m+1) < \cdots < \sigma(m+n)$. For example, when $m = n = 1$, we have

$$(f \wedge g)(u, v) = f(u)g(v) - g(u)f(v).$$

When $m = 1$ and $n \geq 2$, check that

$$(f \wedge g)(u_1, \dots, u_{m+1}) = \sum_{i=1}^{m+1} (-1)^{i-1} f(u_i) g(u_1, \dots, \hat{u}_i, \dots, u_{m+1}),$$

where the hat over the argument u_i means that it should be omitted.

Here is another explicit example. Suppose $m = 2$ and $n = 1$. Given $v_1^*, v_2^*, v_3^* \in E^*$, the multiplication structure on $\bigwedge(E^*)$ implies that $(v_1^* \wedge v_2^*) \cdot v_3^* = v_1^* \wedge v_2^* \wedge v_3^* \in \bigwedge^3(E^*)$. Furthermore, for $u_1, u_2, u_3 \in E$,

$$\begin{aligned} \mu_3(v_1^* \wedge v_2^* \wedge v_3^*)(u_1, u_2, u_3) &= \sum_{\sigma \in \mathfrak{S}_3} \text{sgn}(\sigma) v_{\sigma(1)}^*(u_1) v_{\sigma(2)}^*(u_2) v_{\sigma(3)}^*(u_3) \\ &= v_1^*(u_1) v_2^*(u_2) v_3^*(u_3) - v_1^*(u_1) v_3^*(u_2) v_2^*(u_3) \\ &\quad - v_2^*(u_1) v_1^*(u_2) v_3^*(u_3) + v_2^*(u_1) v_3^*(u_2) v_1^*(u_3) \\ &\quad + v_3^*(u_1) v_1^*(u_2) v_2^*(u_3) - v_3^*(u_1) v_2^*(u_2) v_1^*(u_3). \end{aligned}$$

Now the $(2, 1)$ -shuffles of $\{1, 2, 3\}$ are the following three permutations, namely

$$\begin{pmatrix} 1 & 2 & 3 \\ 1 & 2 & 3 \end{pmatrix}, \quad \begin{pmatrix} 1 & 2 & 3 \\ 1 & 3 & 2 \end{pmatrix}, \quad \begin{pmatrix} 1 & 2 & 3 \\ 2 & 3 & 1 \end{pmatrix}.$$

If $f \cong \mu_2(v_1^* \wedge v_2^*)$ and $g \cong \mu_1(v_3^*)$, then $(**)$ implies that

$$\begin{aligned} (f \cdot g)(u_1, u_2, u_3) &= \sum_{\sigma \in \text{shuffle}(2,1)} \text{sgn}(\sigma) f(u_{\sigma(1)}, u_{\sigma(2)}) g(u_{\sigma(3)}) \\ &= f(u_1, u_2) g(u_3) - f(u_1, u_3) g(u_2) + f(u_2, u_3) g(u_1) \\ &= \mu_2(v_1^* \wedge v_2^*)(u_1, u_2) \mu_1(v_3^*)(u_3) - \mu_2(v_1^* \wedge v_2^*)(u_1, u_3) \mu_1(v_3^*)(u_2) \\ &\quad + \mu_2(v_1^* \wedge v_2^*)(u_2, u_3) \mu_1(v_3^*)(u_1) \\ &= (v_1^*(u_1) v_2^*(u_2) - v_2^*(u_1) v_1^*(u_2)) v_3^*(u_3) \\ &\quad - (v_1^*(u_1) v_2^*(u_3) - v_2^*(u_1) v_1^*(u_3)) v_3^*(u_2) \\ &\quad + (v_1^*(u_2) v_2^*(u_3) - v_2^*(u_2) v_1^*(u_3)) v_3^*(u_1) \\ &= \mu_3(v_1^* \wedge v_2^* \wedge v_3^*)(u_1, u_2, u_3). \end{aligned}$$

As a result of all this, the direct sum

$$\text{Alt}(E) = \bigoplus_{n \geq 0} \text{Alt}^n(E; K)$$

is an algebra under the above multiplication, and this algebra is isomorphic to $\bigwedge(E^*)$. For the record we state

Proposition 34.14. *When E is finite dimensional, the maps $\mu: \bigwedge^n(E^*) \rightarrow \text{Alt}^n(E; K)$ induced by the linear extensions of the maps given by*

$$\mu(v_1^* \wedge \cdots \wedge v_n^*)(u_1, \dots, u_n) = \det(v_j^*(u_i))$$

yield a canonical isomorphism of algebras $\mu: \bigwedge(E^) \rightarrow \text{Alt}(E)$, where the multiplication in $\text{Alt}(E)$ is defined by the maps $\wedge: \text{Alt}^m(E; K) \times \text{Alt}^n(E; K) \rightarrow \text{Alt}^{m+n}(E; K)$, with*

$$(f \wedge g)(u_1, \dots, u_{m+n}) = \sum_{\sigma \in \text{shuffle}(m, n)} \text{sgn}(\sigma) f(u_{\sigma(1)}, \dots, u_{\sigma(m)}) g(u_{\sigma(m+1)}, \dots, u_{\sigma(m+n)}),$$

where $\text{shuffle}(m, n)$ consists of all (m, n) -“shuffles,” that is, permutations σ of $\{1, \dots, m+n\}$ such that $\sigma(1) < \cdots < \sigma(m)$ and $\sigma(m+1) < \cdots < \sigma(m+n)$.

Remark: The algebra $\bigwedge(E)$ is a graded algebra. Given two graded algebras E and F , we can make a new tensor product $E \widehat{\otimes} F$, where $E \widehat{\otimes} F$ is equal to $E \otimes F$ as a vector space, but with a skew-commutative multiplication given by

$$(a \otimes b) \wedge (c \otimes d) = (-1)^{\deg(b)\deg(c)} (ac) \otimes (bd),$$

where $a \in E^m, b \in F^p, c \in E^n, d \in F^q$. Then, it can be shown that

$$\bigwedge(E \oplus F) \cong \bigwedge(E) \widehat{\otimes} \bigwedge(F).$$

34.6 The Hodge *-Operator

In order to define a generalization of the Laplacian that applies to differential forms on a Riemannian manifold, we need to define isomorphisms

$$\bigwedge^k V \longrightarrow \bigwedge^{n-k} V,$$

for any Euclidean vector space V of dimension n and any k , with $0 \leq k \leq n$. If $\langle -, - \rangle$ denotes the inner product on V , we define an inner product on $\bigwedge^k V$, denoted $\langle -, - \rangle_\wedge$, by setting

$$\langle u_1 \wedge \cdots \wedge u_k, v_1 \wedge \cdots \wedge v_k \rangle_\wedge = \det(\langle u_i, v_j \rangle),$$

for all $u_i, v_i \in V$, and extending $\langle -, - \rangle_\wedge$ by bilinearity.

It is easy to show that if (e_1, \dots, e_n) is an orthonormal basis of V , then the basis of $\bigwedge^k V$ consisting of the e_I (where $I = \{i_1, \dots, i_k\}$, with $1 \leq i_1 < \cdots < i_k \leq n$) is an orthonormal basis of $\bigwedge^k V$. Since the inner product on V induces an inner product on V^* (recall that $\langle \omega_1, \omega_2 \rangle = \langle \omega_1^\sharp, \omega_2^\sharp \rangle$, for all $\omega_1, \omega_2 \in V^*$), we also get an inner product on $\bigwedge^k V^*$.

Definition 34.6. An *orientation* of a vector space V of dimension n is given by the choice of some basis (e_1, \dots, e_n) . We say that a basis (u_1, \dots, u_n) of V is *positively oriented* iff $\det(u_1, \dots, u_n) > 0$ (where $\det(u_1, \dots, u_n)$ denotes the determinant of the matrix whose j th column consists of the coordinates of u_j over the basis (e_1, \dots, e_n)), otherwise it is *negatively oriented*. An *oriented vector space* is a vector space V together with an orientation of V .

If V is oriented by the basis (e_1, \dots, e_n) , then V^* is oriented by the dual basis (e_1^*, \dots, e_n^*) . If σ is any permutation of $\{1, \dots, n\}$, then the basis $(e_{\sigma(1)}, \dots, e_{\sigma(n)})$ has positive orientation iff the signature $\text{sgn}(\sigma)$ of the permutation σ is even.

If V is an oriented vector space of dimension n , then we can define a linear isomorphism

$$*: \bigwedge^k V \rightarrow \bigwedge^{n-k} V,$$

called the *Hodge *-operator*. The existence of this operator is guaranteed by the following proposition.

Proposition 34.15. Let V be any oriented Euclidean vector space whose orientation is given by some chosen orthonormal basis (e_1, \dots, e_n) . For any alternating tensor $\alpha \in \bigwedge^k V$, there is a unique alternating tensor $*\alpha \in \bigwedge^{n-k} V$ such that

$$\alpha \wedge \beta = \langle *\alpha, \beta \rangle_\wedge e_1 \wedge \cdots \wedge e_n$$

for all $\beta \in \bigwedge^{n-k} V$. The alternating tensor $*\alpha$ is independent of the choice of the positive orthonormal basis (e_1, \dots, e_n) .

Proof. Since $\bigwedge^n V$ has dimension 1, the alternating tensor $e_1 \wedge \cdots \wedge e_n$ is a basis of $\bigwedge^n V$. It follows that for any fixed $\alpha \in \bigwedge^k V$, the linear map λ_α from $\bigwedge^{n-k} V$ to $\bigwedge^n V$ given by

$$\lambda_\alpha(\beta) = \alpha \wedge \beta$$

is of the form

$$\lambda_\alpha(\beta) = f_\alpha(\beta) e_1 \wedge \cdots \wedge e_n$$

for some linear form $f_\alpha \in (\bigwedge^{n-k} V)^*$. But then, by the duality induced by the inner product $\langle -, - \rangle$ on $\bigwedge^{n-k} V$, there is a unique vector $*\alpha \in \bigwedge^{n-k} V$ such that

$$f_\lambda(\beta) = \langle *\alpha, \beta \rangle_\wedge \quad \text{for all } \beta \in \bigwedge^{n-k} V,$$

which implies that

$$\alpha \wedge \beta = \lambda_\alpha(\beta) = f_\alpha(\beta) e_1 \wedge \cdots \wedge e_n = \langle *\alpha, \beta \rangle_\wedge e_1 \wedge \cdots \wedge e_n,$$

as claimed. If (e'_1, \dots, e'_n) is any other positively oriented orthonormal basis, by Proposition 34.2, $e'_1 \wedge \cdots \wedge e'_n = \det(P) e_1 \wedge \cdots \wedge e_n = e_1 \wedge \cdots \wedge e_n$, since $\det(P) = 1$ where P is the change of basis from (e_1, \dots, e_n) to (e'_1, \dots, e'_n) and both bases are positively oriented. \square

Definition 34.7. The operator $*$ from $\bigwedge^k V$ to $\bigwedge^{n-k} V$ defined by Proposition 34.15 is called the *Hodge *-operator*.

Observe that the Hodge $*$ -operator is linear.

The Hodge $*$ -operator is defined in terms of the orthonormal basis elements of $\bigwedge V$ as follows: For any increasing sequence (i_1, \dots, i_k) of elements $i_p \in \{1, \dots, n\}$, if (j_1, \dots, j_{n-k}) is the increasing sequence of elements $j_q \in \{1, \dots, n\}$ such that

$$\{i_1, \dots, i_k\} \cup \{j_1, \dots, j_{n-k}\} = \{1, \dots, n\},$$

then

$$*(e_{i_1} \wedge \cdots \wedge e_{i_k}) = \text{sign}(i_1, \dots, i_k, j_1, \dots, j_{n-k}) e_{j_1} \wedge \cdots \wedge e_{j_{n-k}}.$$

In particular, for $k = 0$ and $k = n$, we have

$$\begin{aligned} *(1) &= e_1 \wedge \cdots \wedge e_n \\ *(e_1 \wedge \cdots \wedge e_n) &= 1. \end{aligned}$$

For example, if $n = 3$, we have

$$\begin{aligned} *e_1 &= e_2 \wedge e_3 \\ *e_2 &= -e_1 \wedge e_3 \\ *e_3 &= e_1 \wedge e_2 \\ *(e_1 \wedge e_2) &= e_3 \\ *(e_1 \wedge e_3) &= -e_2 \\ *(e_2 \wedge e_3) &= e_1. \end{aligned}$$

The Hodge $*$ -operators $*: \bigwedge^k V \rightarrow \bigwedge^{n-k} V$ induce a linear map $*: \bigwedge(V) \rightarrow \bigwedge(V)$. We also have Hodge $*$ -operators $*: \bigwedge^k V^* \rightarrow \bigwedge^{n-k} V^*$.

The following proposition shows that the linear map $*: \bigwedge(V) \rightarrow \bigwedge(V)$ is an isomorphism.

Proposition 34.16. *If V is any oriented vector space of dimension n , for every k with $0 \leq k \leq n$, we have*

$$(i) \quad ** = (-\text{id})^{k(n-k)}.$$

$$(ii) \quad \langle x, y \rangle_\wedge = *(x \wedge *y) = *(y \wedge *x), \text{ for all } x, y \in \bigwedge^k V.$$

Proof. (1) Let $(e_i)_{i=1}^n$ be an orthonormal basis of V . It is enough to check the identity on basis elements. We have

$$*(e_{i_1} \wedge \cdots \wedge e_{i_k}) = \text{sign}(i_1, \dots, i_k, j_1, \dots, j_{n-k}) e_{j_1} \wedge \cdots \wedge e_{j_{n-k}}$$

and

$$\begin{aligned} **(e_{i_1} \wedge \cdots \wedge e_{i_k}) &= \text{sign}(i_1, \dots, i_k, j_1, \dots, j_{n-k}) * (e_{j_1} \wedge \cdots \wedge e_{j_{n-k}}) \\ &= \text{sign}(i_1, \dots, i_k, j_1, \dots, j_{n-k}) \text{sign}(j_1, \dots, j_{n-k}, i_1, \dots, i_k) e_{i_1} \wedge \cdots \wedge e_{i_k}. \end{aligned}$$

It is easy to see that

$$\text{sign}(i_1, \dots, i_k, j_1, \dots, j_{n-k}) \text{sign}(j_1, \dots, j_{n-k}, i_1, \dots, i_k) = (-1)^{k(n-k)},$$

which yields

$$**(e_{i_1} \wedge \cdots \wedge e_{i_k}) = (-1)^{k(n-k)} e_{i_1} \wedge \cdots \wedge e_{i_k},$$

as claimed.

(ii) These identities are easily checked on basis elements; see Jost [101], Chapter 2, Lemma 2.1.1. In particular let

$$x = e_{i_1} \wedge \cdots \wedge e_{i_k}, \quad y = e_{i_j} \wedge \cdots \wedge e_{i_s}, \quad x, y \in \bigwedge^k V,$$

where $(e_i)_{i=1}^n$ is an orthonormal basis of V . If $x \neq y$, $\langle x, y \rangle_\wedge = 0$ since there is some e_{i_p} of x not equal to any e_{j_q} of y by the orthonormality of the basis, this means the p^{th} row of $(\langle e_{i_l}, e_{j_s} \rangle)$ consists entirely of zeroes. Also $x \neq y$ implies that $y \wedge *x = 0$ since

$$*x = \text{sign}(i_1, \dots, i_k, l_1, \dots, l_{n-k}) e_{l_1} \wedge \cdots \wedge e_{l_{n-k}},$$

where e_{l_s} is the same as some e_p in y . A similar argument shows that if $x \neq y$, $x \wedge *y = 0$. So now assume $x = y$. Then

$$\begin{aligned} *(e_{i_1} \wedge \cdots \wedge e_{i_k} \wedge * (e_{i_1} \wedge \cdots \wedge e_{i_k})) &= *(e_1 \wedge e_2 \wedge \cdots \wedge e_n) \\ &= 1 = \langle x, x \rangle_\wedge. \end{aligned} \quad \square$$

It is possible to express $*(1)$ in terms of any basis (not necessarily orthonormal) of V .

Proposition 34.17. *If V is any finite-dimensional oriented vector space, for any basis (v_1, \dots, v_n) of V , we have*

$$*(1) = \frac{1}{\sqrt{\det(\langle v_i, v_j \rangle)}} v_1 \wedge \cdots \wedge v_n.$$

Proof. If (e_1, \dots, e_n) is an orthonormal basis of V and (v_1, \dots, v_n) is any other basis of V , then

$$\langle v_1 \wedge \cdots \wedge v_n, v_1 \wedge \cdots \wedge v_n \rangle_\wedge = \det(\langle v_i, v_j \rangle),$$

and since

$$v_1 \wedge \cdots \wedge v_n = \det(A) e_1 \wedge \cdots \wedge e_n$$

where A is the matrix expressing the v_j in terms of the e_i , we have

$$\langle v_1 \wedge \cdots \wedge v_n, v_1 \wedge \cdots \wedge v_n \rangle_\wedge = \det(A)^2 \langle e_1 \wedge \cdots \wedge e_n, e_1 \wedge \cdots \wedge e_n \rangle = \det(A)^2.$$

As a consequence, $\det(A) = \sqrt{\det(\langle v_i, v_j \rangle)}$, and

$$v_1 \wedge \cdots \wedge v_n = \sqrt{\det(\langle v_i, v_j \rangle)} e_1 \wedge \cdots \wedge e_n,$$

from which it follows that

$$*(1) = \frac{1}{\sqrt{\det(\langle v_i, v_j \rangle)}} v_1 \wedge \cdots \wedge v_n$$

(see Jost [101], Chapter 2, Lemma 2.1.3). \square

34.7 Left and Right Hooks \circledast

In this section *all vector spaces are assumed to have finite dimension*. Say $\dim(E) = n$. Using our nonsingular pairing

$$\langle -, - \rangle: \bigwedge^p E^* \times \bigwedge^p E \longrightarrow K \quad (1 \leq p \leq n)$$

defined on generators by

$$\langle u_1^* \wedge \cdots \wedge u_p^*, v_1 \wedge \cdots \wedge v_p \rangle = \det(u_i^*(v_j)),$$

we define various contraction operations (partial evaluation operators)

$$\lrcorner: \bigwedge^p E \times \bigwedge^{p+q} E^* \longrightarrow \bigwedge^q E^* \quad (\text{left hook})$$

and

$$\llcorner: \bigwedge^{p+q} E^* \times \bigwedge^p E \longrightarrow \bigwedge^q E^* \quad (\text{right hook}),$$

as well as the versions obtained by replacing E by E^* and E^{**} by E . We begin with the *left interior product or left hook*, \lrcorner .

Let $u \in \bigwedge^p E$. For any q such that $p + q \leq n$, multiplication on the right by u is a linear map

$$\wedge_R(u): \bigwedge^q E \longrightarrow \bigwedge^{p+q} E$$

given by

$$v \mapsto v \wedge u$$

where $v \in \bigwedge^q E$. The transpose of $\wedge_R(u)$ yields a linear map

$$(\wedge_R(u))^\top: \left(\bigwedge^{p+q} E \right)^* \longrightarrow \left(\bigwedge^q E \right)^*,$$

which, using the isomorphisms $\left(\bigwedge^{p+q} E \right)^* \cong \bigwedge^{p+q} E^*$ and $\left(\bigwedge^q E \right)^* \cong \bigwedge^q E^*$, can be viewed as a map

$$(\wedge_R(u))^\top: \bigwedge^{p+q} E^* \longrightarrow \bigwedge^q E^*$$

given by

$$z^* \mapsto z^* \circ \wedge_R(u),$$

where $z^* \in \bigwedge^{p+q} E^*$. We denote $z^* \circ \wedge_R(u)$ by $u \lrcorner z^*$. In terms of our pairing, the adjoint $u \lrcorner$ of $\wedge_R(u)$ defined by

$$\langle u \lrcorner z^*, v \rangle = \langle z^*, \wedge_R(u)(v) \rangle;$$

this in turn leads to the following definition.

Definition 34.8. Let $u \in \bigwedge^p E$ and $z^* \in \bigwedge^{p+q} E^*$. We define $u \lrcorner z^* \in \bigwedge^q E^*$ to be q -vector uniquely determined by

$$\langle u \lrcorner z^*, v \rangle = \langle z^*, v \wedge u \rangle, \quad \text{for all } v \in \bigwedge^q E.$$

Remark: Note that to be precise the operator

$$\lrcorner: \bigwedge^p E \times \bigwedge^{p+q} E^* \longrightarrow \bigwedge^q E^*$$

depends of p, q , so we really defined a family of operators $\lrcorner_{p,q}$. This family of operators $\lrcorner_{p,q}$ induces a map

$$\lrcorner: \bigwedge E \times \bigwedge E^* \longrightarrow \bigwedge E^*,$$

with

$$\lrcorner_{p,q}: \bigwedge^p E \times \bigwedge^{p+q} E^* \longrightarrow \bigwedge^q E^*$$

as defined before. The common practice is to omit the subscripts of \lrcorner .

It is immediately verified that

$$(u \wedge v) \lrcorner z^* = u \lrcorner (v \lrcorner z^*),$$

for all $u \in \bigwedge^k E, v \in \bigwedge^{p-k} E, z^* \in \bigwedge^{p+q} E^*$ since

$$\langle (u \wedge v) \lrcorner z^*, w \rangle = \langle z^*, w \wedge u \wedge v \rangle = \langle v \lrcorner z^*, w \wedge u \rangle = \langle u \lrcorner (v \lrcorner z^*), w \rangle,$$

whenever $w \in \bigwedge^q E$. This means that

$$\lrcorner : \bigwedge E \times \bigwedge E^* \longrightarrow \bigwedge E^*$$

is a left action of the (noncommutative) ring $\bigwedge E$ with multiplication \wedge on $\bigwedge E^*$, which makes $\bigwedge E^*$ into a left $\bigwedge E$ -module.

By interchanging E and E^* and using the isomorphism

$$\left(\bigwedge^k F \right)^* \cong \bigwedge^k F^*,$$

we can also define some maps

$$\lrcorner : \bigwedge^p E^* \times \bigwedge^{p+q} E \longrightarrow \bigwedge^q E,$$

and make the following definition.

Definition 34.9. Let $u^* \in \bigwedge^p E^*$, and $z \in \bigwedge^{p+q} E$. We define $u^* \lrcorner z \in \bigwedge^q E$ as the q -vector uniquely defined by

$$\langle v^* \wedge u^*, z \rangle = \langle v^*, u^* \lrcorner z \rangle, \quad \text{for all } v^* \in \bigwedge^q E^*.$$

As for the previous version, we have a family of operators $\lrcorner_{p,q}$ which define an operator

$$\lrcorner : \bigwedge E^* \times \bigwedge E \longrightarrow \bigwedge E.$$

We easily verify that

$$(u^* \wedge v^*) \lrcorner z = u^* \lrcorner (v^* \lrcorner z),$$

whenever $u^* \in \bigwedge^k E^*$, $v^* \in \bigwedge^{p-k} E^*$, and $z \in \bigwedge^{p+q} E$; so this version of \lrcorner is a left action of the ring $\bigwedge E^*$ on $\bigwedge E$ which makes $\bigwedge E$ into a left $\bigwedge E^*$ -module.

In order to proceed any further we need some combinatorial properties of the basis of $\bigwedge^p E$ constructed from a basis (e_1, \dots, e_n) of E . Recall that for any (nonempty) subset $I \subseteq \{1, \dots, n\}$, we let

$$e_I = e_{i_1} \wedge \cdots \wedge e_{i_p},$$

where $I = \{i_1, \dots, i_p\}$ with $i_1 < \cdots < i_p$. We also let $e_\emptyset = 1$.

Given any two nonempty subsets $H, L \subseteq \{1, \dots, n\}$ both listed in increasing order, say $H = \{h_1 < \dots < h_p\}$ and $L = \{\ell_1 < \dots < \ell_q\}$, if H and L are disjoint, let $H \cup L$ be union of H and L considered as the ordered sequence

$$(h_1, \dots, h_p, \ell_1, \dots, \ell_q).$$

Then let

$$\rho_{H,L} = \begin{cases} 0 & \text{if } H \cap L \neq \emptyset, \\ (-1)^\nu & \text{if } H \cap L = \emptyset, \end{cases}$$

where

$$\nu = |\{(h, l) \mid (h, l) \in H \times L, h > l\}|.$$

Observe that when $H \cap L = \emptyset$, $|H| = p$ and $|L| = q$, the number ν is the number of inversions of the sequence

$$(h_1, \dots, h_p, \ell_1, \dots, \ell_q),$$

where an inversion is a pair (h_i, ℓ_j) such that $h_i > \ell_j$.

Unless $p + q = n$, the function whose graph is given by

$$\begin{pmatrix} 1 & \cdots & p & p+1 & \cdots & p+q \\ h_1 & \cdots & h_p & \ell_1 & \cdots & \ell_q \end{pmatrix}$$

is **not** a permutation of $\{1, \dots, n\}$. We can view ν as a slight generalization of the notion of the number of inversions of a permutation.

Proposition 34.18. *For any basis (e_1, \dots, e_n) of E the following properties hold:*

(1) *If $H \cap L = \emptyset$, $|H| = p$, and $|L| = q$, then*

$$\rho_{H,L}\rho_{L,H} = (-1)^\nu(-1)^{pq-\nu} = (-1)^{pq}.$$

(2) *For $H, L \subseteq \{1, \dots, m\}$ listed in increasing order, we have*

$$e_H \wedge e_L = \rho_{H,L} e_{H \cup L}.$$

Similarly,

$$e_H^* \wedge e_L^* = \rho_{H,L} e_{H \cup L}^*.$$

(3) *For the left hook*

$$\lrcorner : \bigwedge^p E \times \bigwedge^{p+q} E^* \longrightarrow \bigwedge^q E^*,$$

we have

$$\begin{aligned} e_H \lrcorner e_L^* &= 0 && \text{if } H \not\subseteq L \\ e_H \lrcorner e_L^* &= \rho_{L-H,H} e_{L-H}^* && \text{if } H \subseteq L. \end{aligned}$$

(4) *For the left hook*

$$\lrcorner : \bigwedge^p E^* \times \bigwedge^{p+q} E \longrightarrow \bigwedge^q E,$$

we have

$$\begin{aligned} e_H^* \lrcorner e_L &= 0 && \text{if } H \not\subseteq L \\ e_H^* \lrcorner e_L &= \rho_{L-H,H} e_{L-H} && \text{if } H \subseteq L. \end{aligned}$$

Proof. These are proved in Bourbaki [25] (Chapter III, §11, Section 11), but the proofs of (3) and (4) are very concise. We elaborate on the proofs of (2) and (4), the proof of (3) being similar.

In (2) if $H \cap L \neq \emptyset$, then $e_H \wedge e_L$ contains some vector twice and so $e_H \wedge e_L = 0$. Otherwise, $e_H \wedge e_L$ consists of

$$e_{h_1} \wedge \cdots \wedge e_{h_p} \wedge e_{\ell_1} \wedge \cdots \wedge e_{\ell_q},$$

and to order the sequence of indices in increasing order we need to transpose any two indices (h_i, ℓ_j) corresponding to an inversion, which yields $\rho_{H,L} e_{H \cup L}$.

Let us now consider (4). We have $|L| = p + q$ and $|H| = p$, and the q -vector $e_H^* \lrcorner e_L$ is characterized by

$$\langle v^*, e_H^* \lrcorner e_L \rangle = \langle v^* \wedge e_H^*, e_L \rangle$$

for all $v^* \in \bigwedge^q E^*$. There are two cases.

Case 1: $H \not\subseteq L$. If so, no matter what $v^* \in \bigwedge^q E^*$ is, since H contains some index h not in L , the h th row $(e_h^*(e_{\ell_1}), \dots, e_h^*(e_{\ell_{p+q}}))$ of the determinant $\langle v^* \wedge e_H^*, e_L \rangle$ must be zero, so $\langle v^* \wedge e_H^*, e_L \rangle = 0$ for all $v^* \in \bigwedge^q E^*$, and since the pairing is nongenerate, we must have $e_H^* \lrcorner e_L = 0$.

Case 2: $H \subseteq L$. In this case, for $v^* = e_{L-H}^*$, by (2) we have

$$\langle e_{L-H}^*, e_H^* \lrcorner e_L \rangle = \langle e_{L-H}^* \wedge e_H^*, e_L \rangle = \langle \rho_{L-H,H} e_L^*, e_L \rangle = \rho_{L-H,H},$$

which yields

$$\langle e_{L-H}^*, e_H^* \lrcorner e_L \rangle = \rho_{L-H,H}.$$

The q -vector $e_H^* \lrcorner e_L$ can be written as a linear combination $e_H^* \lrcorner e_L = \sum_J \lambda_J e_J$ with $|J| = q$ so

$$\langle e_{L-H}^*, e_H^* \lrcorner e_L \rangle = \sum_J \lambda_J \langle e_{L-H}^*, e_J \rangle.$$

By definition of the pairing, $\langle e_{L-H}^*, e_J \rangle = 0$ unless $J = L - H$, which means that

$$\langle e_{L-H}^*, e_H^* \lrcorner e_L \rangle = \lambda_{L-H} \langle e_{L-H}^*, e_{L-H} \rangle = \lambda_{L-H},$$

so $\lambda_{L-H} = \rho_{L-H,H}$, as claimed. □

Using Proposition 34.18, we have the

Proposition 34.19. *For the left hook*

$$\lrcorner : E \times \bigwedge^{q+1} E^* \longrightarrow \bigwedge^q E^*,$$

for every $u \in E$, $x^* \in \bigwedge^{q+1-s} E^*$, and $y^* \in \bigwedge^s E^*$, we have

$$u \lrcorner (x^* \wedge y^*) = (-1)^s (u \lrcorner x^*) \wedge y^* + x^* \wedge (u \lrcorner y^*).$$

Proof. We can prove the above identity assuming that x^* and y^* are of the form e_I^* and e_J^* using Proposition 34.18 and leave the details as an exercise for the reader. \square

Thus, $\lrcorner : E \times \bigwedge^{q+1} E^* \rightarrow \bigwedge^q E^*$ is almost an anti-derivation, except that the sign $(-1)^s$ is applied to the wrong factor.

We have a similar identity for the other version of the left hook

$$\lrcorner : E^* \times \bigwedge^{q+1} E \rightarrow \bigwedge^q E,$$

namely

$$u^* \lrcorner (x \wedge y) = (-1)^s (u^* \lrcorner x) \wedge y + x \wedge (u^* \lrcorner y)$$

for every $u^* \in E^*$, $x \in \bigwedge^{q+1-s} E$, and $y \in \bigwedge^s E$.

An application of this formula when $q = 3$ and $s = 2$ yields an interesting equation. In this case, $u^* \in E^*$ and $x, y \in \bigwedge^2 E$, so we get

$$u^* \lrcorner (x \wedge y) = (u^* \lrcorner x) \wedge y + x \wedge (u^* \lrcorner y).$$

In particular, for $x = y$, since $x \in \bigwedge^2 E$ and $u^* \lrcorner x \in E$, Proposition 34.12 implies that $(u^* \lrcorner x) \wedge x = x \wedge (u^* \lrcorner x)$, and we obtain

$$u^* \lrcorner (x \wedge x) = 2((u^* \lrcorner x) \wedge x). \quad (\dagger)$$

As a consequence, $(u^* \lrcorner x) \wedge x = 0$ iff $u^* \lrcorner (x \wedge x) = 0$. We will use this identity together with Proposition 34.25 to prove that a 2-vector $x \in \bigwedge^2 E$ is decomposable iff $x \wedge x = 0$.

It is also possible to define a *right interior product or right hook* \llcorner , using multiplication on the left rather than multiplication on the right. Then we use the maps

$$\llcorner : \bigwedge^{p+q} E^* \times \bigwedge^p E \rightarrow \bigwedge^q E^*$$

to make the following definition.

Definition 34.10. Let $u \in \bigwedge^p E$ and $z^* \in \bigwedge^{p+q} E^*$. We define $z^* \llcorner u \in \bigwedge^q E^*$ to be the q -vector uniquely defined as

$$\langle z^* \llcorner u, v \rangle = \langle z^*, u \wedge v \rangle, \quad \text{for all } v \in \bigwedge^q E.$$

This time we can prove that

$$z^* \llcorner (u \wedge v) = (z^* \llcorner u) \llcorner v,$$

so the family of operators $\llcorner_{p,q}$ defines a right action

$$\llcorner : \bigwedge E^* \times \bigwedge E \rightarrow \bigwedge E^*$$

of the ring $\bigwedge E$ on $\bigwedge E^*$ which makes $\bigwedge E^*$ into a right $\bigwedge E$ -module.

Similarly, we have maps

$$\llcorner : \bigwedge^{p+q} E \times \bigwedge^p E^* \longrightarrow \bigwedge^q E$$

which in turn leads to the following dual formation of the right hook.

Definition 34.11. Let $u^* \in \bigwedge^p E^*$ and $z \in \bigwedge^{p+q} E$. We define $z \llcorner u^* \in \bigwedge^q E$ to be the q -vector uniquely defined by

$$\langle u^* \wedge v^*, z \rangle = \langle v^*, z \llcorner u^* \rangle, \quad \text{for all } v^* \in \bigwedge^q E^*.$$

We can prove that

$$z \llcorner (u^* \wedge v^*) = (z \llcorner u^*) \llcorner v^*,$$

so the family of operators $\llcorner_{p,q}$ defines a right action

$$\llcorner : \bigwedge E \times \bigwedge E^* \longrightarrow \bigwedge E$$

of the ring $\bigwedge E^*$ on $\bigwedge E$ which makes $\bigwedge E$ into a right $\bigwedge E^*$ -module.

Since the left hook $\lrcorner : \bigwedge^p E \times \bigwedge^{p+q} E^* \longrightarrow \bigwedge^q E^*$ is defined by

$$\langle u \lrcorner z^*, v \rangle = \langle z^*, v \wedge u \rangle, \quad \text{for all } u \in \bigwedge^p E, v \in \bigwedge^q E \text{ and } z^* \in \bigwedge^{p+q} E^*,$$

the right hook

$$\llcorner : \bigwedge^{p+q} E^* \times \bigwedge^p E \longrightarrow \bigwedge^q E^*$$

by

$$\langle z^* \llcorner u, v \rangle = \langle z^*, u \wedge v \rangle, \quad \text{for all } u \in \bigwedge^p E, v \in \bigwedge^q E \text{ and } z^* \in \bigwedge^{p+q} E^*,$$

and $v \wedge u = (-1)^{pq} u \wedge v$, we conclude that

$$z^* \llcorner u = (-1)^{pq} u \lrcorner z^*.$$

Similarly, since

$$\begin{aligned} \langle v^* \wedge u^*, z \rangle &= \langle v^*, u^* \lrcorner z \rangle, \quad \text{for all } u^* \in \bigwedge^p E^*, v^* \in \bigwedge^q E^* \text{ and } z \in \bigwedge^{p+q} E \\ \langle u^* \wedge v^*, z \rangle &= \langle v^*, z \llcorner u^* \rangle, \quad \text{for all } u^* \in \bigwedge^p E^*, v^* \in \bigwedge^q E^*, \text{ and } z \in \bigwedge^{p+q} E, \end{aligned}$$

and $v^* \wedge u^* = (-1)^{pq} u^* \wedge v^*$, we have

$$z \llcorner u^* = (-1)^{pq} u^* \lrcorner z.$$

We summarize the above facts in the following proposition.

Proposition 34.20. *The following identities hold:*

$$\begin{aligned} z^* \lrcorner u &= (-1)^{pq} u \lrcorner z^* \quad \text{for all } u \in \bigwedge^p E \text{ and all } z^* \in \bigwedge^{p+q} E^* \\ z \lrcorner u^* &= (-1)^{pq} u^* \lrcorner z \quad \text{for all } u^* \in \bigwedge^p E^* \text{ and all } z \in \bigwedge^{p+q} E. \end{aligned}$$

Therefore the left and right hooks are not independent, and in fact each one determines the other. As a consequence, we can restrict our attention to only one of the hooks, for example the left hook, but there are a few situations where it is nice to use both, for example in Proposition 34.23.

A version of Proposition 34.18 holds for right hooks, but beware that the indices in $\rho_{L-H,H}$ are permuted. This permutation has to do with the fact that the left hook and the right hook are related *via* a sign factor.

Proposition 34.21. *For any basis (e_1, \dots, e_n) of E the following properties hold:*

(1) *For the right hook*

$$\lrcorner : \bigwedge^{p+q} E \times \bigwedge^p E^* \longrightarrow \bigwedge^q E$$

we have

$$\begin{aligned} e_L \lrcorner e_H^* &= 0 \quad \text{if } H \not\subseteq L \\ e_L \lrcorner e_H^* &= \rho_{H,L-H} e_{L-H} \quad \text{if } H \subseteq L. \end{aligned}$$

(2) *For the right hook*

$$\lrcorner : \bigwedge^{p+q} E^* \times \bigwedge^p E \longrightarrow \bigwedge^q E^*$$

we have

$$\begin{aligned} e_L^* \lrcorner e_H &= 0 \quad \text{if } H \not\subseteq L \\ e_L^* \lrcorner e_H &= \rho_{H,L-H} e_{L-H}^* \quad \text{if } H \subseteq L. \end{aligned}$$

Remark: Our definition of left hooks as left actions $\lrcorner : \bigwedge^p E \times \bigwedge^{p+q} E^* \longrightarrow \bigwedge^q E^*$ and $\lrcorner : \bigwedge^p E^* \times \bigwedge^{p+q} E \longrightarrow \bigwedge^q E$ and right hooks as right actions $\lrcorner : \bigwedge^{p+q} E^* \times \bigwedge^p E \longrightarrow \bigwedge^q E^*$ and $\lrcorner : \bigwedge^{p+q} E \times \bigwedge^p E^* \longrightarrow \bigwedge^q E$ is identical to the definition found in Fulton and Harris [68] (Appendix B). However, the reader should be aware that this is not a universally accepted notation. In fact, the left hook $u^* \lrcorner z$ defined in Bourbaki [25] is our right hook $z \lrcorner u^*$, up to the sign $(-1)^{p(p-1)/2}$. This has to do with the fact that Bourbaki uses a different pairing which also involves an extra sign, namely

$$\langle v^*, u^* \lrcorner z \rangle = (-1)^{p(p-1)/2} \langle u^* \wedge v^*, z \rangle.$$

One of the side-effects of this choice is that Bourbaki's version of Formula (4) of Proposition 34.18 (Bourbaki [25], Chapter III, page 168) is

$$\begin{aligned} e_H^* \lrcorner e_L &= 0 \quad \text{if } H \not\subseteq L \\ e_H^* \lrcorner e_L &= (-1)^{p(p-1)/2} \rho_{H,L-H} e_{L-H} \quad \text{if } H \subseteq L, \end{aligned}$$

where $|H| = p$ and $|L| = p + q$. This correspond to Formula (1) of Proposition 34.21 up to the sign factor $(-1)^{p(p-1)/2}$, which we find horribly confusing. Curiously, an older edition of Bourbaki (1958) uses the same pairing as Fulton and Harris [68]. The reason (and the advantage) for this change of sign convention is not clear to us.

We also have the following version of Proposition 34.19 for the right hook.

Proposition 34.22. *For the right hook*

$$\llcorner : \bigwedge^{q+1} E^* \times E \longrightarrow \bigwedge^q E^*,$$

for every $u \in E$, $x^* \in \bigwedge^r E^*$, and $y^* \in \bigwedge^{q+1-r} E^*$, we have

$$(x^* \wedge y^*) \llcorner u = (x^* \llcorner u) \wedge y^* + (-1)^r x^* \wedge (y^* \llcorner u).$$

Proof. A proof involving determinants can be found in Warner [186], Chapter 2. \square

Thus, $\llcorner : \bigwedge^{q+1} E^* \times E \longrightarrow \bigwedge^q E^*$ is an anti-derivation. A similar formula holds for the right hook $\llcorner : \bigwedge^{q+1} E \times E^* \longrightarrow \bigwedge^q E$, namely

$$(x \wedge y) \llcorner u^* = (x \llcorner u^*) \wedge y + (-1)^r x \wedge (y \llcorner u^*),$$

for every $u^* \in E$, $\in \bigwedge^r E$, and $y \in \bigwedge^{q+1-r} E$. This formula is used by Shafarevitch [158] to define a hook, but beware that Shafarevitch use the left hook notation $u^* \lrcorner x$ rather than the right hook notation. Shafarevitch uses the terminology *convolution*, which seems very unfortunate.

For $u \in E$, the right hook $z^* \llcorner u$ is also denoted $i(u)z^*$, and called *insertion operator* or *interior product*. This operator plays an important role in differential geometry.

Definition 34.12. Let $u \in E$ and $z^* \in \bigwedge^{n+1}(E^*)$. If we view z^* as an alternating multilinear map in $\text{Alt}^{n+1}(E; K)$, then we define $i(u)z^* \in \text{Alt}^n(E; K)$ as given by

$$(i(u)z^*)(v_1, \dots, v_n) = z^*(u, v_1, \dots, v_n).$$

Using the left hook \lrcorner and the right hook \llcorner we can define two linear maps $\gamma: \bigwedge^p E \rightarrow \bigwedge^{n-p} E^*$ and $\delta: \bigwedge^p E^* \rightarrow \bigwedge^{n-p} E$ as follows:

Definition 34.13. For any basis (e_1, \dots, e_n) of E , if we let $M = \{1, \dots, n\}$, $e = e_1 \wedge \dots \wedge e_n$, and $e^* = e_1^* \wedge \dots \wedge e_n^*$, define $\gamma: \bigwedge^p E \rightarrow \bigwedge^{n-p} E^*$ and $\delta: \bigwedge^p E^* \rightarrow \bigwedge^{n-p} E$ as

$$\gamma(u) = u \lrcorner e^* \quad \text{and} \quad \delta(v^*) = e \lrcorner v^*,$$

for all $u \in \bigwedge^p E$ and all $v^* \in \bigwedge^p E^*$.

Proposition 34.23. *The linear maps $\gamma: \bigwedge^p E \rightarrow \bigwedge^{n-p} E^*$ and $\delta: \bigwedge^p E^* \rightarrow \bigwedge^{n-p} E$ are isomorphisms, and $\gamma^{-1} = \delta$. The isomorphisms γ and δ map decomposable vectors to decomposable vectors. Furthermore, if $z \in \bigwedge^p E$ is decomposable, say $z = u_1 \wedge \dots \wedge u_p$ for some $u_i \in E$, then $\gamma(z) = v_1^* \wedge \dots \wedge v_{n-p}^*$ for some $v_j^* \in E^*$, and $v_j^*(u_i) = 0$ for all i, j . A similar property holds for $v^* \in \bigwedge^p E^*$ and $\delta(v^*)$. If (e'_1, \dots, e'_n) is any other basis of E and $\gamma': \bigwedge^p E \rightarrow \bigwedge^{n-p} E^*$ and $\delta': \bigwedge^p E^* \rightarrow \bigwedge^{n-p} E$ are the corresponding isomorphisms, then $\gamma' = \lambda \gamma$ and $\delta' = \lambda^{-1} \delta$ for some nonzero $\lambda \in K$.*

Proof. Using Propositions 34.18 and 34.21, for any subset $J \subseteq \{1, \dots, n\} = M$ such that $|J| = p$, we have

$$\gamma(e_J) = e_J \lrcorner e^* = \rho_{M-J,J} e_{M-J}^* \quad \text{and} \quad \delta(e_{M-J}^*) = e \lrcorner e_{M-J}^* = \rho_{M-J,J} e_J.$$

Thus,

$$\delta \circ \gamma(e_J) = \rho_{M-J,J} \rho_{M-J,J} e_J = e_J,$$

since $\rho_{M-J,J} = \pm 1$. A similar result holds for $\gamma \circ \delta$. This implies that

$$\delta \circ \gamma = \text{id} \quad \text{and} \quad \gamma \circ \delta = \text{id}.$$

Thus, γ and δ are inverse isomorphisms.

If $z \in \bigwedge^p E$ is decomposable, then $z = u_1 \wedge \dots \wedge u_p$ where u_1, \dots, u_p are linearly independent since $z \neq 0$, and we can pick a basis of E of the form (u_1, \dots, u_n) . Then the above formulae show that

$$\gamma(z) = \pm u_{p+1}^* \wedge \dots \wedge u_n^*.$$

Since (u_1^*, \dots, u_n^*) is the dual basis of (u_1, \dots, u_n) , we have $u_i^*(u_j) = \delta_{ij}$. If (e'_1, \dots, e'_n) is any other basis of E , because $\bigwedge^n E$ has dimension 1, we have

$$e'_1 \wedge \dots \wedge e'_n = \lambda e_1 \wedge \dots \wedge e_n$$

for some nonzero $\lambda \in K$, and the rest is trivial. \square

Applying Proposition 34.23 to the case where $p = n - 1$, the isomorphism $\gamma: \bigwedge^{n-1} E \rightarrow \bigwedge^1 E^*$ maps indecomposable vectors in $\bigwedge^{n-1} E$ to indecomposable vectors in $\bigwedge^1 E^* = E^*$. But every vector in E^* is decomposable, so every vector in $\bigwedge^{n-1} E$ is decomposable.

Corollary 34.24. *If E is a finite-dimensional vector space, then every vector in $\bigwedge^{n-1} E$ is decomposable.*

34.8 Testing Decomposability \circledast

We are now ready to tackle the problem of finding criteria for decomposability. Such criteria will use the left hook. Once again, in this section *all vector spaces are assumed to have finite dimension*. But before stating our criteria, we need a few preliminary results.

Proposition 34.25. *Given $z \in \bigwedge^p E$ with $z \neq 0$, the smallest vector space $W \subseteq E$ such that $z \in \bigwedge^p W$ is generated by the vectors of the form*

$$u^* \lrcorner z, \quad \text{with } u^* \in \bigwedge^{p-1} E^*.$$

Proof. First let W be any subspace such that $z \in \bigwedge^p(W)$ and let $(e_1, \dots, e_r, e_{r+1}, \dots, e_n)$ be a basis of E such that (e_1, \dots, e_r) is a basis of W . Then, $u^* = \sum_I \lambda_I e_I^*$, where $I \subseteq \{1, \dots, n\}$ and $|I| = p - 1$, and $z = \sum_J \mu_J e_J$, where $J \subseteq \{1, \dots, r\}$ and $|J| = p \leq r$. It follows immediately from the formula of Proposition 34.18 (4), namely

$$e_I^* \lrcorner e_J = \rho_{J-I, J} e_{J-I},$$

that $u^* \lrcorner z \in W$, since $J - I \subseteq \{1, \dots, r\}$.

Next we prove that if W is the smallest subspace of E such that $z \in \bigwedge^p(W)$, then W is generated by the vectors of the form $u^* \lrcorner z$, where $u^* \in \bigwedge^{p-1} E^*$. Suppose not. Then the vectors $u^* \lrcorner z$ with $u^* \in \bigwedge^{p-1} E^*$ span a proper subspace U of W . We prove that for every subspace W' of W with $\dim(W') = \dim(W) - 1 = r - 1$, it is not possible that $u^* \lrcorner z \in W'$ for all $u^* \in \bigwedge^{p-1} E^*$. But then, as U is a proper subspace of W , it is contained in some subspace W' with $\dim(W') = r - 1$, and we have a contradiction.

Let $w \in W - W'$ and pick a basis of W formed by a basis (e_1, \dots, e_{r-1}) of W' and w . Any $z \in \bigwedge^p(W)$ can be written as $z = z' + w \wedge z''$, where $z' \in \bigwedge^p W'$ and $z'' \in \bigwedge^{p-1} W'$, and since W is the smallest subspace containing z , we have $z'' \neq 0$. Consequently, if we write $z'' = \sum_I \lambda_I e_I$ in terms of the basis (e_1, \dots, e_{r-1}) of W' , there is some e_I , with $I \subseteq \{1, \dots, r-1\}$ and $|I| = p - 1$, so that the coefficient λ_I is nonzero. Now, using any basis of E containing (e_1, \dots, e_{r-1}, w) , by Proposition 34.18 (4), we see that

$$e_I^* \lrcorner (w \wedge e_I) = \lambda w, \quad \lambda = \pm 1.$$

It follows that

$$e_I^* \lrcorner z = e_I^* \lrcorner (z' + w \wedge z'') = e_I^* \lrcorner z' + e_I^* \lrcorner (w \wedge z'') = e_I^* \lrcorner z' + \lambda \lambda_I w,$$

with $e_I^* \lrcorner z' \in W'$, which shows that $e_I^* \lrcorner z \notin W'$. Therefore, W is indeed generated by the vectors of the form $u^* \lrcorner z$, where $u^* \in \bigwedge^{p-1} E^*$. \square

To help understand Proposition 34.25, let E be the vector space with basis $\{e_1, e_2, e_3, e_4\}$ and $z = e_1 \wedge e_2 + e_2 \wedge e_3$. Note that $z \in \bigwedge^2 E$. To find the smallest vector space $W \subseteq E$

such that $z \in \bigwedge^2 W$, we calculate $u^* \lrcorner z$, where $u^* \in \bigwedge^1 E^*$. The multilinearity of \lrcorner implies it is enough to calculate $u^* \lrcorner z$ for $u^* \in \{e_1^*, e_2^*, e_3^*, e_4^*\}$. Proposition 34.18 (4) implies that

$$\begin{aligned} e_1^* \lrcorner z &= e_1^* \lrcorner (e_1 \wedge e_2 + e_2 \wedge e_3) = e_1^* \lrcorner e_1 \wedge e_2 = -e_2 \\ e_2^* \lrcorner z &= e_2^* \lrcorner (e_1 \wedge e_2 + e_2 \wedge e_3) = e_1 - e_3 \\ e_3^* \lrcorner z &= e_3^* \lrcorner (e_1 \wedge e_2 + e_2 \wedge e_3) = e_3^* \lrcorner e_2 \wedge e_3 = e_2 \\ e_4^* \lrcorner z &= e_4^* \lrcorner (e_1 \wedge e_2 + e_2 \wedge e_3) = 0. \end{aligned}$$

Thus W is the two-dimensional vector space generated by the basis $\{e_2, e_1 - e_3\}$. This is not surprising since $z = -e_2 \wedge (e_1 - e_3)$ and is in fact decomposable. As this example demonstrates, the action of the left hook provides a way of extracting a basis of W from z .

Proposition 34.25 implies the following corollary.

Corollary 34.26. *Any nonzero $z \in \bigwedge^p E$ is decomposable iff the smallest subspace W of E such that $z \in \bigwedge^p W$ has dimension p . Furthermore, if $z = u_1 \wedge \cdots \wedge u_p$ is decomposable, then (u_1, \dots, u_p) is a basis of the smallest subspace W of E such that $z \in \bigwedge^p W$*

Proof. If $\dim(W) = p$, then for any basis (e_1, \dots, e_p) of W we know that $\bigwedge^p W$ has $e_1 \wedge \cdots \wedge e_p$ as a basis, and thus has dimension 1. Since $z \in \bigwedge^p W$, we have $z = \lambda e_1 \wedge \cdots \wedge e_p$ for some nonzero λ , so z is decomposable.

Conversely assume that $z \in \bigwedge^p W$ is nonzero and decomposable. Then, $z = u_1 \wedge \cdots \wedge u_p$, and since $z \neq 0$, by Proposition 34.8 (u_1, \dots, u_p) are linearly independent. Then for any $v_i^* = u_1^* \wedge \cdots \wedge u_{i-1}^* \wedge u_{i+1}^* \wedge \cdots \wedge u_p^*$ (where u_i^* is omitted), we have

$$v_i^* \lrcorner z = (u_1^* \wedge \cdots \wedge u_{i-1}^* \wedge u_{i+1}^* \wedge \cdots \wedge u_p^*) \lrcorner (u_1 \wedge \cdots \wedge u_p) = \pm u_i,$$

so by Proposition 34.25 we have $u_i \in W$ for $i = 1, \dots, p$. This shows that $\dim(W) \geq p$, but since $z = u_1 \wedge \cdots \wedge u_p$, we have $\dim(W) = p$, which means that (u_1, \dots, u_p) is a basis of W . \square

Finally we are ready to state and prove the criterion for decomposability with respect to left hooks.

Proposition 34.27. *Any nonzero $z \in \bigwedge^p E$ is decomposable iff*

$$(u^* \lrcorner z) \wedge z = 0, \quad \text{for all } u^* \in \bigwedge^{p-1} E^*.$$

Proof. First assume that $z \in \bigwedge^p E$ is decomposable. If so, by Corollary 34.26, the smallest subspace W of E such that $z \in \bigwedge^p W$ has dimension p , so we have $z = e_1 \wedge \cdots \wedge e_p$ where e_1, \dots, e_p form a basis of W . By Proposition 34.25, for every $u^* \in \bigwedge^{p-1} E^*$, we have $u^* \lrcorner z \in W$, so each $u^* \lrcorner z$ is a linear combination of the e_i 's, say

$$u^* \lrcorner z = \alpha_1 e_1 + \cdots + \alpha_p e_p,$$

and

$$(u^* \lrcorner z) \wedge z = \sum_{i=1}^p \alpha_i e_i \wedge e_1 \wedge \cdots \wedge e_i \wedge \cdots \wedge e_p = 0.$$

Now assume that $(u^* \lrcorner z) \wedge z = 0$ for all $u^* \in \bigwedge^{p-1} E^*$, and that $\dim(W) = m > p$, where W is the smallest subspace of E such that $z \in \bigwedge^p W$. If e_1, \dots, e_m is a basis of W , then we have $z = \sum_I \lambda_I e_I$, where $I \subseteq \{1, \dots, m\}$ and $|I| = p$. Recall that $z \neq 0$, and so, some λ_I is nonzero. By Proposition 34.25, each e_i can be written as $u^* \lrcorner z$ for some $u^* \in \bigwedge^{p-1} E^*$, and since $(u^* \lrcorner z) \wedge z = 0$ for all $u^* \in \bigwedge^{p-1} E^*$, we get

$$e_j \wedge z = 0 \quad \text{for } j = 1, \dots, m.$$

By wedging $z = \sum_I \lambda_I e_I$ with each e_j , as $m > p$, we deduce $\lambda_I = 0$ for all I , so $z = 0$, a contradiction. Therefore, $m = p$ and Corollary 34.26 implies that z is decomposable. \square

As a corollary of Proposition 34.27 we obtain the following fact that we stated earlier without proof.

Proposition 34.28. *Given any vector space E of dimension n , a vector $x \in \bigwedge^2 E$ is decomposable iff $x \wedge x = 0$.*

Proof. Recall that as an application of Proposition 34.19 we proved the formula (\dagger) , namely

$$u^* \lrcorner (x \wedge x) = 2((u^* \lrcorner x) \wedge x)$$

for all $x \in \bigwedge^2 E$ and all $u^* \in E^*$. As a consequence, $(u^* \lrcorner x) \wedge x = 0$ iff $u^* \lrcorner (x \wedge x) = 0$. By Proposition 34.27, the 2-vector x is decomposable iff $u^* \lrcorner (x \wedge x) = 0$ for all $u^* \in E^*$ iff $x \wedge x = 0$. Therefore, a 2-vector x is decomposable iff $x \wedge x = 0$. \square

As an application of Proposition 34.28, assume that $\dim(E) = 3$ and that (e_1, e_2, e_3) is a basis of E . Then any 2-vector $x \in \bigwedge^2 E$ is of the form

$$x = \alpha e_1 \wedge e_2 + \beta e_1 \wedge e_3 + \gamma e_2 \wedge e_3.$$

We have

$$x \wedge x = (\alpha e_1 \wedge e_2 + \beta e_1 \wedge e_3 + \gamma e_2 \wedge e_3) \wedge (\alpha e_1 \wedge e_2 + \beta e_1 \wedge e_3 + \gamma e_2 \wedge e_3) = 0,$$

because all the terms involved are of the form $c e_{i_1} \wedge e_{i_2} \wedge e_{i_3} \wedge e_{i_4}$ with $i_1, i_2, i_3, i_4 \in \{1, 2, 3\}$, and so at least two of these indices are identical. Therefore, every 2-vector $x = \alpha e_1 \wedge e_2 + \beta e_1 \wedge e_3 + \gamma e_2 \wedge e_3$ is decomposable, although this is not obvious at first glance. For example,

$$e_1 \wedge e_2 + e_1 \wedge e_3 + e_2 \wedge e_3 = (e_1 + e_2) \wedge (e_2 + e_3).$$

We now show that Proposition 34.27 yields an equational criterion for the decomposability of an alternating tensor $z \in \bigwedge^p E$.

34.9 The Grassmann-Plücker's Equations and Grassmannian Manifolds \circledast

We follow an argument adapted from Bourbaki [25] (Chapter III, §11, Section 13).

Let E be a vector space of dimensions n , let (e_1, \dots, e_n) be a basis of E , and let (e_1^*, \dots, e_n^*) be its dual basis. Our objective is to determine whether a nonzero vector $z \in \bigwedge^p E$ is decomposable. By Proposition 34.27, the vector z is decomposable iff $(u^* \lrcorner z) \wedge z = 0$ for all $u^* \in \bigwedge^{p-1} E^*$. We can let u^* range over a basis of $\bigwedge^{p-1} E^*$, and then the conditions are

$$(e_H^* \lrcorner z) \wedge z = 0$$

for all $H \subseteq \{1, \dots, n\}$, with $|H| = p - 1$. Since $(e_H^* \lrcorner z) \wedge z \in \bigwedge^{p+1} E$, this is equivalent to

$$\langle e_J^*, (e_H^* \lrcorner z) \wedge z \rangle = 0$$

for all $H, J \subseteq \{1, \dots, n\}$, with $|H| = p - 1$ and $|J| = p + 1$. Then, for all $I, I' \subseteq \{1, \dots, n\}$ with $|I| = |I'| = p$, Formulae (2) and (4) of Proposition 34.18 show that

$$\langle e_J^*, (e_H^* \lrcorner e_I) \wedge e_{I'} \rangle = 0,$$

unless there is some $i \in \{1, \dots, n\}$ such that

$$I - H = \{i\}, \quad J - I' = \{i\}.$$

In this case, $I = H \cup \{i\}$ and $I' = J - \{i\}$, and using Formulae (2) and (4) of Proposition 34.18, we have

$$\langle e_J^*, (e_H^* \lrcorner e_{H \cup \{i\}}) \wedge e_{J - \{i\}} \rangle = \langle e_J^*, \rho_{\{i\}, H} e_i \wedge e_{J - \{i\}} \rangle = \langle e_J^*, \rho_{\{i\}, H} \rho_{\{i\}, J - \{i\}} e_J \rangle = \rho_{\{i\}, H} \rho_{\{i\}, J - \{i\}}.$$

If we let

$$\epsilon_{i, J, H} = \rho_{\{i\}, H} \rho_{\{i\}, J - \{i\}},$$

we have $\epsilon_{i, J, H} = +1$ if the parity of the number of $j \in J$ such that $j < i$ is the same as the parity of the number of $h \in H$ such that $h < i$, and $\epsilon_{i, J, H} = -1$ otherwise.

Finally we obtain the following criterion in terms of quadratic equations (*Plücker's equations*) for the decomposability of an alternating tensor.

Proposition 34.29. (*Grassmann-Plücker's Equations*) For $z = \sum_I \lambda_I e_I \in \bigwedge^p E$, the conditions for $z \neq 0$ to be decomposable are

$$\sum_{i \in J - H} \epsilon_{i, J, H} \lambda_{H \cup \{i\}} \lambda_{J - \{i\}} = 0,$$

with $\epsilon_{i, J, H} = \rho_{\{i\}, H} \rho_{\{i\}, J - \{i\}}$, for all $H, J \subseteq \{1, \dots, n\}$ such that $|H| = p - 1$, $|J| = p + 1$, and all $i \in J - H$.

Using the above criterion, it is a good exercise to reprove that if $\dim(E) = n$, then every tensor in $\bigwedge^{n-1}(E)$ is decomposable. We already proved this fact as a corollary of Proposition 34.23.

Given any $z = \sum_I \lambda_I e_I \in \bigwedge^p E$ where $\dim(E) = n$, the family of scalars (λ_I) (with $I = \{i_1 < \dots < i_p\} \subseteq \{1, \dots, n\}$ listed in increasing order) is called the *Plücker coordinates* of z . The Grassmann-Plücker's equations give necessary and sufficient conditions for any nonzero z to be decomposable.

For example, when $\dim(E) = n = 4$ and $p = 2$, these equations reduce to the single equation

$$\lambda_{12}\lambda_{34} - \lambda_{13}\lambda_{24} + \lambda_{14}\lambda_{23} = 0.$$

However, it should be noted that the equations given by Proposition 34.29 are not independent in general.

We are now in the position to prove that the Grassmannian $G(p, n)$ can be embedded in the projective space $\mathbb{RP}^{\binom{n}{p}-1}$,

For any $n \geq 1$ and any k with $1 \leq p \leq n$, recall that the Grassmannian $G(p, n)$ is the set of all linear p -dimensional subspaces of \mathbb{R}^n (also called *p -planes*). Any p -dimensional subspace U of \mathbb{R}^n is spanned by p linearly independent vectors u_1, \dots, u_p in \mathbb{R}^n ; write $U = \text{span}(u_1, \dots, u_p)$. By Proposition 34.8, (u_1, \dots, u_p) are linearly independent iff $u_1 \wedge \dots \wedge u_p \neq 0$. If (v_1, \dots, v_p) are any other linearly independent vectors spanning U , then we have

$$v_j = \sum_{i=1}^p a_{ij} u_i, \quad 1 \leq j \leq p,$$

for some $a_{ij} \in \mathbb{R}$, and by Proposition 34.2

$$v_1 \wedge \dots \wedge v_p = \det(A) u_1 \wedge \dots \wedge u_p,$$

where $A = (a_{ij})$. As a consequence, we can define a map $i_G: G(p, n) \rightarrow \mathbb{RP}^{\binom{n}{p}-1}$ such that for any k -plane U , for any basis (u_1, \dots, u_p) of U ,

$$i_G(U) = [u_1 \wedge \dots \wedge u_p],$$

the point of $\mathbb{RP}^{\binom{n}{p}-1}$ given by the one-dimensional subspace of $\mathbb{R}^{\binom{n}{p}}$ spanned by $u_1 \wedge \dots \wedge u_p$.

Proposition 34.30. *The map $i_G: G(p, n) \rightarrow \mathbb{RP}^{\binom{n}{p}-1}$ is injective.*

Proof. Let U and V be any two p -planes and assume that $i_G(U) = i_G(V)$. This means that there is a basis (u_1, \dots, u_p) of U and a basis (v_1, \dots, v_p) of V such that

$$v_1 \wedge \dots \wedge v_p = c u_1 \wedge \dots \wedge u_p$$

for some nonzero $c \in \mathbb{R}$. The above implies that the smallest subspaces W and W' of \mathbb{R}^n such that $u_1 \wedge \cdots \wedge u_p \in \bigwedge^p W$ and $v_1 \wedge \cdots \wedge v_p \in \bigwedge^p W'$ are identical, so $W = W'$. By Corollary 34.26, this smallest subspace W has both (u_1, \dots, u_p) and (v_1, \dots, v_p) as bases, so the v_j are linear combinations of the u_i (and vice-versa), and $U = V$. \square

Since any nonzero $z \in \bigwedge^p \mathbb{R}^n$ can be uniquely written as

$$z = \sum_I \lambda_I e_I$$

in terms of its Plücker coordinates (λ_I) , every point of $\mathbb{RP}_{(p)}^{(n)-1}$ is defined by the Plücker coordinates (λ_I) viewed as homogeneous coordinates. The points of $\mathbb{RP}_{(p)}^{(n)-1}$ corresponding to one-dimensional spaces associated with decomposable alternating p -tensors are the points whose coordinates satisfy the Grassmann-Plücker's equations of Proposition 34.29. Therefore, the map i_G embeds the Grassmannian $G(p, n)$ as an algebraic variety in $\mathbb{RP}_{(p)}^{(n)-1}$ defined by equations of degree 2.

We can replace the field \mathbb{R} by \mathbb{C} in the above reasoning and we obtain an embedding of the complex Grassmannian $G_{\mathbb{C}}(p, n)$ as an algebraic variety in $\mathbb{CP}_{(p)}^{(n)-1}$ defined by equations of degree 2.

In particular, if $n = 4$ and $p = 2$, the equation

$$\lambda_{12}\lambda_{34} - \lambda_{13}\lambda_{24} + \lambda_{14}\lambda_{23} = 0$$

is the homogeneous equation of a quadric in \mathbb{CP}^5 known as the *Klein quadric*. The points on this quadric are in one-to-one correspondence with the lines in \mathbb{CP}^3 .

There is also a simple algebraic criterion to decide whether the smallest subspaces U and V associated with two nonzero decomposable vectors $u_1 \wedge \cdots \wedge u_p$ and $v_1 \wedge \cdots \wedge v_q$ have a nontrivial intersection.

Proposition 34.31. *Let E be any n -dimensional vector space over a field K , and let U and V be the smallest subspaces of E associated with two nonzero decomposable vectors $u = u_1 \wedge \cdots \wedge u_p \in \bigwedge^p U$ and $v = v_1 \wedge \cdots \wedge v_q \in \bigwedge^q V$. The following properties hold:*

- (1) *We have $U \cap V = (0)$ iff $u \wedge v \neq 0$.*
- (2) *If $U \cap V = (0)$, then $U + V$ is the least subspace associated with $u \wedge v$.*

Proof. Assume $U \cap V = (0)$. We know by Corollary 34.26 that (u_1, \dots, u_p) is a basis of U and (v_1, \dots, v_q) is a basis of V . Since $U \cap V = (0)$, $(u_1, \dots, u_p, v_1, \dots, v_q)$ is a basis of $U + V$, and by Proposition 34.8, we have

$$u \wedge v = u_1 \wedge \cdots \wedge u_p \wedge v_1 \wedge \cdots \wedge v_q \neq 0.$$

This also proves (2).

Conversely, assume that $\dim(U \cap V) \geq 1$. Pick a basis (w_1, \dots, w_r) of $W = U \cap V$, and extend this basis to a basis $(w_1, \dots, w_r, w_{r+1}, \dots, w_p)$ of U and to a basis $(w_1, \dots, w_r, w_{p+1}, \dots, w_{p+q-r})$ of V . By Corollary 34.26, (u_1, \dots, u_p) is also basis of U , so

$$u_1 \wedge \cdots \wedge u_p = a w_1 \wedge \cdots \wedge w_r \wedge w_{r+1} \wedge \cdots \wedge w_p$$

for some $a \in K$, and (v_1, \dots, v_q) is also basis of V , so

$$v_1 \wedge \cdots \wedge v_q = b w_1 \wedge \cdots \wedge w_r \wedge w_{p+1} \wedge \cdots \wedge w_{p+q-r}$$

for some $b \in K$, and thus

$$u \wedge v = u_1 \wedge \cdots \wedge u_p \wedge v_1 \wedge \cdots \wedge v_q = 0$$

since it contains some repeated w_i , with $1 \leq i \leq r$. \square

As an application of Proposition 34.31, consider two projective lines D_1 and D_2 in \mathbb{RP}^3 , which means that D_1 and D_2 correspond to two 2-planes in \mathbb{R}^4 , and thus by Proposition 34.30, to two points in $\mathbb{RP}^{(4)_2-1} = \mathbb{RP}^5$. These two points correspond to the 2-vectors

$$z = a_{1,2}e_1 \wedge e_2 + a_{1,3}e_1 \wedge e_3 + a_{1,4}e_1 \wedge e_4 + a_{2,3}e_2 \wedge e_3 + a_{2,4}e_2 \wedge e_4 + a_{3,4}e_3 \wedge e_4$$

and

$$z' = a'_{1,2}e_1 \wedge e_2 + a'_{1,3}e_1 \wedge e_3 + a'_{1,4}e_1 \wedge e_4 + a'_{2,3}e_2 \wedge e_3 + a'_{2,4}e_2 \wedge e_4 + a'_{3,4}e_3 \wedge e_4$$

whose Plücker coordinates, (where $a_{i,j} = \lambda_{ij}$), satisfy the equation

$$\lambda_{12}\lambda_{34} - \lambda_{13}\lambda_{24} + \lambda_{14}\lambda_{23} = 0$$

of the Klein quadric, and D_1 and D_2 intersect iff $z \wedge z' = 0$ iff

$$a_{1,2}a'_{3,4} - a_{1,3}a'_{3,4} + a_{1,4}a'_{2,3} + a_{2,3}a'_{1,4} - a_{2,4}a'_{1,3} + a_{3,4}a'_{1,2} = 0.$$

Observe that for D_1 fixed, this is a linear condition. This fact is very helpful for solving problems involving intersections of lines. A famous problem is to find how many lines in \mathbb{RP}^3 meet four given lines in general position. The answer is at most 2.

34.10 Vector-Valued Alternating Forms

The purpose of this section is to present the technical background needed to understand vector-valued differential forms, in particular in the case of Lie groups where differential forms taking their values in a Lie algebra arise naturally.

In this section the vector space E is assumed to have *finite dimension*. We know that there is a canonical isomorphism $\bigwedge^n(E^*) \cong \text{Alt}^n(E; K)$ between alternating n -forms and

alternating multilinear maps. As in the case of general tensors, the isomorphisms provided by Propositions 34.5, 33.17, and 34.10, namely

$$\begin{aligned}\mathrm{Alt}^n(E; F) &\cong \mathrm{Hom}\left(\bigwedge^n(E), F\right) \\ \mathrm{Hom}\left(\bigwedge^n(E), F\right) &\cong \left(\bigwedge^n(E)\right)^* \otimes F \\ \left(\bigwedge^n(E)\right)^* &\cong \bigwedge^n(E^*)\end{aligned}$$

yield a canonical isomorphism

$$\mathrm{Alt}^n(E; F) \cong \left(\bigwedge^n(E^*)\right) \otimes F$$

which we record as a corollary.

Corollary 34.32. *For any finite-dimensional vector space E and any vector space F , we have a canonical isomorphism*

$$\mathrm{Alt}^n(E; F) \cong \left(\bigwedge^n(E^*)\right) \otimes F.$$

Note that F may have infinite dimension. This isomorphism allows us to view the tensors in $\bigwedge^n(E^*) \otimes F$ as *vector-valued alternating forms*, a point of view that is useful in differential geometry. If (f_1, \dots, f_r) is a basis of F , every tensor $\omega \in \bigwedge^n(E^*) \otimes F$ can be written as some linear combination

$$\omega = \sum_{i=1}^r \alpha_i \otimes f_i,$$

with $\alpha_i \in \bigwedge^n(E^*)$. We also let

$$\bigwedge(E; F) = \bigoplus_{n=0}^{\infty} \left(\bigwedge^n(E^*)\right) \otimes F = \left(\bigwedge(E)\right) \otimes F.$$

Given three vector spaces, F, G, H , if we have some bilinear map $\Phi: F \times G \rightarrow H$, then we can define a multiplication operation

$$\wedge_\Phi: \bigwedge(E; F) \times \bigwedge(E; G) \rightarrow \bigwedge(E; H)$$

as follows: For every pair (m, n) , we define the multiplication

$$\wedge_\Phi: \left(\left(\bigwedge^m(E^*)\right) \otimes F\right) \times \left(\left(\bigwedge^n(E^*)\right) \otimes G\right) \longrightarrow \left(\bigwedge^{m+n}(E^*)\right) \otimes H$$

by

$$\omega \wedge_{\Phi} \eta = (\alpha \otimes f) \wedge_{\Phi} (\beta \otimes g) = (\alpha \wedge \beta) \otimes \Phi(f, g).$$

As in Section 34.5 (following H. Cartan [35]), we can also define a multiplication

$$\wedge_{\Phi}: \text{Alt}^m(E; F) \times \text{Alt}^n(E; G) \longrightarrow \text{Alt}^{m+n}(E; H)$$

directly on alternating multilinear maps as follows: For $f \in \text{Alt}^m(E; F)$ and $g \in \text{Alt}^n(E; G)$,

$$(f \wedge_{\Phi} g)(u_1, \dots, u_{m+n}) = \sum_{\sigma \in \text{shuffle}(m, n)} \text{sgn}(\sigma) \Phi\left(f(u_{\sigma(1)}, \dots, u_{\sigma(m)}), g(u_{\sigma(m+1)}, \dots, u_{\sigma(m+n)})\right),$$

where $\text{shuffle}(m, n)$ consists of all (m, n) -“shuffles;” that is, permutations σ of $\{1, \dots, m+n\}$ such that $\sigma(1) < \dots < \sigma(m)$ and $\sigma(m+1) < \dots < \sigma(m+n)$.

A special case of interest is the case where $F = G = H$ is a Lie algebra and $\Phi(a, b) = [a, b]$ is the Lie bracket of F . In this case, using a basis (f_1, \dots, f_r) of F , if we write $\omega = \sum_i \alpha_i \otimes f_i$ and $\eta = \sum_j \beta_j \otimes f_j$, we have

$$\omega \wedge_{\Phi} \eta = [\omega, \eta] = \sum_{i,j} \alpha_i \wedge \beta_j \otimes [f_i, f_j].$$

It is customary to denote $\omega \wedge_{\Phi} \eta$ by $[\omega, \eta]$ (unfortunately, the bracket notation is overloaded). Consequently,

$$[\eta, \omega] = (-1)^{mn+1} [\omega, \eta].$$

In general not much can be said about \wedge_{Φ} , unless Φ has some additional properties. In particular, \wedge_{Φ} is generally not associative.

We now use vector-valued alternating forms to generalize both the μ map of Proposition 34.14 and generalize Proposition 33.17 by defining the map

$$\mu_F: \left(\bigwedge^n(E^*)\right) \otimes F \longrightarrow \text{Alt}^n(E; F)$$

on generators by

$$\mu_F((v_1^* \wedge \dots \wedge v_n^*) \otimes f)(u_1, \dots, u_n) = (\det(v_j^*(u_i)) f,$$

with $v_1^*, \dots, v_n^* \in E^*$, $u_1, \dots, u_n \in E$, and $f \in F$.

Proposition 34.33. *The map*

$$\mu_F: \left(\bigwedge^n(E^*)\right) \otimes F \longrightarrow \text{Alt}^n(E; F)$$

defined as above is a canonical isomorphism for every $n \geq 0$. Furthermore, given any three vector spaces, F, G, H , and any bilinear map $\Phi: F \times G \rightarrow H$, for all $\omega \in (\bigwedge^n(E^*)) \otimes F$ and all $\eta \in (\bigwedge^n(E^*)) \otimes G$,

$$\mu_H(\omega \wedge_{\Phi} \eta) = \mu_F(\omega) \wedge_{\Phi} \mu_G(\eta).$$

Proof. Since we already know that $(\bigwedge^n(E^*)) \otimes F$ and $\text{Alt}^n(E; F)$ are isomorphic, it is enough to show that μ_F maps some basis of $(\bigwedge^n(E^*)) \otimes F$ to linearly independent elements. Pick some bases (e_1, \dots, e_p) in E and $(f_j)_{j \in J}$ in F . Then we know that the vectors $e_I^* \otimes f_j$, where $I \subseteq \{1, \dots, p\}$ and $|I| = n$, form a basis of $(\bigwedge^n(E^*)) \otimes F$. If we have a linear dependence

$$\sum_{I,j} \lambda_{I,j} \mu_F(e_I^* \otimes f_j) = 0,$$

applying the above combination to each $(e_{i_1}, \dots, e_{i_n})$ ($I = \{i_1, \dots, i_n\}$, $i_1 < \dots < i_n$), we get the linear combination

$$\sum_j \lambda_{I,j} f_j = 0,$$

and by linear independence of the f_j 's, we get $\lambda_{I,j} = 0$ for all I and all j . Therefore, the $\mu_F(e_I^* \otimes f_j)$ are linearly independent, and we are done. The second part of the proposition is checked using a simple computation. \square

The following proposition will be useful in dealing with vector-valued differential forms.

Proposition 34.34. *If (e_1, \dots, e_p) is any basis of E , then every element $\omega \in (\bigwedge^n(E^*)) \otimes F$ can be written in a unique way as*

$$\omega = \sum_I e_I^* \otimes f_I, \quad f_I \in F,$$

where the e_I^* are defined as in Section 34.2.

Proof. Since, by Proposition 34.7, the e_I^* form a basis of $\bigwedge^n(E^*)$, elements of the form $e_I^* \otimes f$ span $(\bigwedge^n(E^*)) \otimes F$. Now if we apply $\mu_F(\omega)$ to $(e_{i_1}, \dots, e_{i_n})$, where $I = \{i_1, \dots, i_n\} \subseteq \{1, \dots, p\}$, we get

$$\mu_F(\omega)(e_{i_1}, \dots, e_{i_n}) = \mu_F(e_I^* \otimes f_I)(e_{i_1}, \dots, e_{i_n}) = f_I.$$

Therefore, the f_I are uniquely determined by f . \square

Proposition 34.34 can also be formulated in terms of alternating multilinear maps, a fact that will be useful to deal with differential forms.

Corollary 34.35. *Define the product $\cdot : \text{Alt}^n(E; \mathbb{R}) \times F \rightarrow \text{Alt}^n(E; F)$ as follows: For all $\omega \in \text{Alt}^n(E; \mathbb{R})$ and all $f \in F$,*

$$(\omega \cdot f)(u_1, \dots, u_n) = \omega(u_1, \dots, u_n)f,$$

for all $u_1, \dots, u_n \in E$. Then for every $\omega \in (\bigwedge^n(E^*)) \otimes F$ of the form

$$\omega = u_1^* \wedge \cdots \wedge u_n^* \otimes f,$$

we have

$$\mu_F(u_1^* \wedge \cdots \wedge u_n^* \otimes f) = \mu_F(u_1^* \wedge \cdots \wedge u_n^*) \cdot f.$$

Then Proposition 34.34 yields the following result.

Proposition 34.36. *If (e_1, \dots, e_p) is any basis of E , then every element $\omega \in \text{Alt}^n(E; F)$ can be written in a unique way as*

$$\omega = \sum_I e_I^* \cdot f_I, \quad f_I \in F,$$

where the e_I^* are defined as in Section 34.2.

34.11 Problems

Problem 34.1. Complete the induction argument used in the proof of Proposition 34.1 (2).

Problem 34.2. Prove Proposition 34.2.

Problem 34.3. Prove Proposition 34.9.

Problem 34.4. Show that the pairing given by $(*)$ in Section 34.4 is nondegenerate.

Problem 34.5. Let \mathfrak{I}_a be the two-sided ideal generated by all tensors of the form $u \otimes u \in V^{\otimes 2}$. Prove that

$$\bigwedge^m(V) \cong V^{\otimes m} / (\mathfrak{I}_a \cap V^{\otimes m}).$$

Problem 34.6. Complete the induction proof of Proposition 34.12.

Problem 34.7. Prove the following lemma: If V is a vector space with $\dim(V) \leq 3$, then $\alpha \wedge \alpha = 0$ whenever $\alpha \in \bigwedge(V)$.

Problem 34.8. Prove Proposition 34.13.

Problem 34.9. Given two graded algebras E and F , define $E \hat{\otimes} F$ to be the vector space $E \otimes F$, but with a skew-commutative multiplication given by

$$(a \otimes b) \wedge (c \otimes d) = (-1)^{\deg(b)\deg(c)}(ac) \otimes (bd),$$

where $a \in E^m, b \in F^p, c \in E^n, d \in F^q$. Show that

$$\bigwedge(E \oplus F) \cong \bigwedge(E) \hat{\otimes} \bigwedge(F).$$

Problem 34.10. If $\langle -, - \rangle$ denotes the inner product on V , recall that we defined an inner product on $\bigwedge^k V$, also denoted $\langle -, - \rangle$, by setting

$$\langle u_1 \wedge \cdots \wedge u_k, v_1 \wedge \cdots \wedge v_k \rangle = \det(\langle u_i, v_j \rangle),$$

for all $u_i, v_i \in V$, and extending $\langle -, - \rangle$ by bilinearity.

Show that if (e_1, \dots, e_n) is an orthonormal basis of V , then the basis of $\bigwedge^k V$ consisting of the e_I (where $I = \{i_1, \dots, i_k\}$, with $1 \leq i_1 < \cdots < i_k \leq n$) is also an orthonormal basis of $\bigwedge^k V$.

Problem 34.11. Show that

$$(u^* \wedge v^*) \lrcorner z = u^* \lrcorner (v^* \lrcorner z),$$

whenever $u^* \in \bigwedge^k E^*$, $v^* \in \bigwedge^{p-k} E^*$, and $z \in \bigwedge^{p+q} E$.

Problem 34.12. Prove Statement (3) of Proposition 34.18.

Problem 34.13. Prove Proposition 34.19.

Also prove the identity

$$u^* \lrcorner (x \wedge y) = (-1)^s (u^* \lrcorner x) \wedge y + x \wedge (u^* \lrcorner y),$$

where $u^* \in E^*$, $x \in \bigwedge^{q+1-s} E$, and $y \in \bigwedge^s E$.

Problem 34.14. Use the Grassmann-Plücker's equations prove that if $\dim(E) = n$, then every tensor in $\bigwedge^{n-1}(E)$ is decomposable.

Problem 34.15. Recall that the map

$$\mu_F: \left(\bigwedge^n (E^*) \right) \otimes F \longrightarrow \text{Alt}^n(E; F)$$

is defined on generators by

$$\mu_F((v_1^* \wedge \cdots \wedge v_n^*) \otimes f)(u_1, \dots, u_n) = (\det(v_j^*(u_i)))f,$$

with $v_1^*, \dots, v_n^* \in E^*$, $u_1, \dots, u_n \in E$, and $f \in F$.

Given any three vector spaces, F, G, H , and any bilinear map $\Phi: F \times G \rightarrow H$, for all $\omega \in (\bigwedge^n (E^*)) \otimes F$ and all $\eta \in (\bigwedge^n (E^*)) \otimes G$ prove that

$$\mu_H(\omega \wedge_\Phi \eta) = \mu_F(\omega) \wedge_\Phi \mu_G(\eta).$$

Chapter 35

Introduction to Modules; Modules over a PID

35.1 Modules over a Commutative Ring

In this chapter we introduce modules over a commutative ring (with unity). After a quick overview of fundamental concepts such as free modules, torsion modules, and some basic results about them, we focus on finitely generated modules over a PID and we prove the structure theorems for this class of modules (invariant factors and elementary divisors). Our main goal is not to give a comprehensive exposition of modules, but instead to apply the structure theorem to the $K[X]$ -module E_f defined by a linear map f acting on a finite-dimensional vector space E , and to obtain several normal forms for f , including the rational canonical form.

A module is the generalization of a vector space E over a field K obtained replacing the field K by a commutative ring A (with unity 1). Although formally the definition is the same, the fact that some nonzero elements of A are not invertible has some serious consequences. For example, it is possible that $\lambda \cdot u = 0$ for some nonzero $\lambda \in A$ and some nonzero $u \in E$, and a module may no longer have a basis.

For the sake of completeness, we give the definition of a module, although it is the same as Definition 3.1 with the field K replaced by a ring A . In this chapter, *all rings under consideration are assumed to be commutative and to have an identity element 1*.

Definition 35.1. Given a ring A , a (*left*) *module over A* (or *A -module*) is a set M (of vectors) together with two operations $+ : M \times M \rightarrow M$ (called *vector addition*),¹ and $\cdot : A \times M \rightarrow M$ (called *scalar multiplication*) satisfying the following conditions for all $\alpha, \beta \in A$ and all $u, v \in M$;

(M0) M is an abelian group w.r.t. $+$, with identity element 0;

¹The symbol $+$ is overloaded, since it denotes both addition in the ring A and addition of vectors in M . It is usually clear from the context which $+$ is intended.

$$(M1) \quad \alpha \cdot (u + v) = (\alpha \cdot u) + (\alpha \cdot v);$$

$$(M2) \quad (\alpha + \beta) \cdot u = (\alpha \cdot u) + (\beta \cdot u);$$

$$(M3) \quad (\alpha * \beta) \cdot u = \alpha \cdot (\beta \cdot u);$$

$$(M4) \quad 1 \cdot u = u.$$

Given $\alpha \in A$ and $v \in M$, the element $\alpha \cdot v$ is also denoted by αv . The ring A is often called the ring of scalars.

Unless specified otherwise or unless we are dealing with several different rings, in the rest of this chapter, we assume that all A -modules are defined with respect to a fixed ring A . Thus, we will refer to a A -module simply as a module.

From (M0), a module always contains the null vector 0, and thus is nonempty. From (M1), we get $\alpha \cdot 0 = 0$, and $\alpha \cdot (-v) = -(\alpha \cdot v)$. From (M2), we get $0 \cdot v = 0$, and $(-\alpha) \cdot v = -(\alpha \cdot v)$. The ring A itself can be viewed as a module over itself, addition of vectors being addition in the ring, and multiplication by a scalar being multiplication in the ring.

When the ring A is a field, an A -module is a vector space. When $A = \mathbb{Z}$, a \mathbb{Z} -module is just an abelian group, with the action given by

$$\begin{aligned} 0 \cdot u &= 0, \\ n \cdot u &= \underbrace{u + \cdots + u}_n, & n > 0 \\ n \cdot u &= -(-n) \cdot u, & n < 0. \end{aligned}$$

All definitions from Section 3.4, linear combinations, linear independence and linear dependence, subspaces renamed as *submodules*, apply unchanged to modules. Proposition 3.5 also holds for the module spanned by a set of vectors. The definition of a basis (Definition 3.6) also applies to modules, but the only result from Section 3.5 that holds for modules is Proposition 3.12. Unfortunately, it is longer true that every module has a basis. For example, for any nonzero integer $n \in \mathbb{Z}$, the \mathbb{Z} -module $\mathbb{Z}/n\mathbb{Z}$ has no basis since $n \cdot \bar{x} = 0$ for all $\bar{x} \in \mathbb{Z}/n\mathbb{Z}$. Similarly, \mathbb{Q} , as a \mathbb{Z} -module, has no basis. Any two distinct nonzero elements p_1/q_1 and p_2/q_2 are linearly dependent, since

$$(p_2q_1) \left(\frac{p_1}{q_1} \right) - (p_1q_2) \left(\frac{p_2}{q_2} \right) = 0.$$

Furthermore, the \mathbb{Z} -module \mathbb{Q} is not finitely generated. For if $\{p_1/q_1, \dots, p_n/q_n\} \subset \mathbb{Q}$ generated \mathbb{Q} , then for any $x = r/s \in \mathbb{Q}$, we have

$$c_1 \frac{p_1}{q_1} + \cdots + c_n \frac{p_n}{q_n} = \frac{r}{s},$$

where $c_i \in \mathbb{Z}$ for $i = 1, \dots, n$. The left hand side of the preceding line is equivalent to

$$\frac{c_1 p_1 q_2 \cdots q_n + \cdots + c_n p_n q_1 \cdots q_{n-1}}{q_1 q_2 \cdots q_n},$$

where the numerator is an element of the ideal in \mathbb{Z} spanned by (c_1, c_2, \dots, c_n) . Since \mathbb{Z} is a PID, there exists $a \in \mathbb{Z}$ such that (a) is the ideal spanned by (c_1, c_2, \dots, c_n) . Thus

$$c_1 \frac{p_1}{q_1} + \cdots + c_n \frac{p_n}{q_n} = \frac{ma}{q_1 q_2 \cdots q_n} = \frac{r}{s},$$

where $m \in \mathbb{Z}$. Set

$$\frac{a}{q_1 q_2 \cdots q_n} = \frac{a_1}{b}, \quad (a_1, b) = 1.$$

Then if \mathbb{Q} was a finitely generated \mathbb{Z} -module, we deduce that for all $x \in \mathbb{Q}$

$$x = \frac{r}{s} = m \frac{a_1}{b},$$

whenever a_1/b is a fixed rational number, clearly a contradiction. (In particular let $x = 1/p$ where p is a fixed prime $p > b$. If $ma_1/b = 1/p$, then $ma_1 \in \mathbb{Z}$ with $ma_1 = b_1/p$, an impossibility since $(b_1, p) = 1$ and $p > b_1$.)

Definition 3.11 can be generalized to rings and yields free modules.

Definition 35.2. Given a commutative ring A and any (nonempty) set I , let $A^{(I)}$ be the subset of the cartesian product A^I consisting of all families $(\lambda_i)_{i \in I}$ with finite support of scalars in A .² We define addition and multiplication by a scalar as follows:

$$(\lambda_i)_{i \in I} + (\mu_i)_{i \in I} = (\lambda_i + \mu_i)_{i \in I},$$

and

$$\lambda \cdot (\mu_i)_{i \in I} = (\lambda \mu_i)_{i \in I}.$$

It is immediately verified that addition and multiplication by a scalar are well defined. Thus, $A^{(I)}$ is a module. Furthermore, because families with finite support are considered, the family $(e_i)_{i \in I}$ of vectors e_i , defined such that $(e_i)_j = 0$ if $j \neq i$ and $(e_i)_i = 1$, is clearly a basis of the module $A^{(I)}$. When $I = \{1, \dots, n\}$, we denote $A^{(I)}$ by A^n . The function $\iota: I \rightarrow A^{(I)}$, such that $\iota(i) = e_i$ for every $i \in I$, is clearly an injection.

Definition 35.3. An A -module M is *free* iff it has a basis.

The module $A^{(I)}$ is a free module.

All definitions from Section 3.7 apply to modules, linear maps, kernel, image, except the definition of rank, which has to be defined differently. Propositions 3.14, 3.15, 3.16, and

²Where A^I denotes the set of all functions from I to A .

3.17 hold for modules. However, the other propositions do not generalize to modules. The definition of an isomorphism generalizes to modules. As a consequence, a module is free iff it is isomorphic to a module of the form $A^{(I)}$.

Section 3.8 generalizes to modules. Given a submodule N of a module M , we can define the quotient module M/N .

If \mathfrak{a} is an ideal in A and if M is an A -module, we define $\mathfrak{a}M$ as the set of finite sums of the form

$$a_1m_1 + \cdots + a_km_k, \quad a_i \in \mathfrak{a}, m_i \in M.$$

It is immediately verified that $\mathfrak{a}M$ is a submodule of M .

Interestingly, the part of Theorem 3.11 that asserts that any two bases of a vector space have the same cardinality holds for modules. One way to prove this fact is to “pass” to a vector space by a quotient process.

Theorem 35.1. *For any free module M , any two bases of M have the same cardinality.*

Proof sketch. We give the argument for finite bases, but it also holds for infinite bases. The trick is to pick any maximal ideal \mathfrak{m} in A (whose existence is guaranteed by Theorem C.3). Then, A/\mathfrak{m} is a field, and $M/\mathfrak{m}M$ can be made into a vector space over A/\mathfrak{m} ; we leave the details as an exercise. If (u_1, \dots, u_n) is a basis of M , then it is easy to see that the image of this basis is a basis of the vector space $M/\mathfrak{m}M$. By Theorem 3.11, the number n of elements in any basis of $M/\mathfrak{m}M$ is an invariant, so any two bases of M must have the same number of elements. \square

Definition 35.4. The common number of elements in any basis of a free module is called the *dimension* (or *rank*) of the free module.

One should realize that the notion of linear independence in a module is a little tricky. According to the definition, the one-element sequence (u) consisting of a single nonzero vector is linearly independent if for all $\lambda \in A$, if $\lambda u = 0$ then $\lambda = 0$. However, there are free modules that contain nonzero vectors that are not linearly independent! For example, the ring $A = \mathbb{Z}/6\mathbb{Z}$ viewed as a module over itself has the basis (1) , but the zero-divisors, such as 2 or 4 , are not linearly independent. Using language introduced in Definition 35.5, a free module may have torsion elements. There are also nonfree modules such that every nonzero vector is linearly independent, such as \mathbb{Q} over \mathbb{Z} .

All definitions from Section 4.1 about matrices apply to free modules, and so do all the propositions. Similarly, all definitions from Section 6.1 about direct sums and direct products apply to modules. All propositions that do not involve extending bases still hold. The important Proposition 6.15 survives in the following form.

Proposition 35.2. *Let $f: E \rightarrow F$ be a surjective linear map between two A -modules with F a free module. Given any basis (v_1, \dots, v_r) of F , for any r vectors $u_1, \dots, u_r \in E$ such that $f(u_i) = v_i$ for $i = 1, \dots, r$, the vectors (u_1, \dots, u_r) are linearly independent and the module E is the direct sum*

$$E = \text{Ker}(f) \oplus U,$$

where U is the free submodule of E spanned by the basis (u_1, \dots, u_r) .

Proof. Pick any $w \in E$, write $f(w)$ over the basis (v_1, \dots, v_r) as $f(w) = a_1v_1 + \dots + a_rv_r$, and let $u = a_1u_1 + \dots + a_ru_r$. Observe that

$$\begin{aligned} f(w - u) &= f(w) - f(u) \\ &= a_1v_1 + \dots + a_rv_r - (a_1f(u_1) + \dots + a_rf(u_r)) \\ &= a_1v_1 + \dots + a_rv_r - (a_1v_1 + \dots + a_rv_r) \\ &= 0. \end{aligned}$$

Therefore, $h = w - u \in \text{Ker}(f)$, and since $w = h + u$ with $h \in \text{Ker}(f)$ and $u \in U$, we have $E = \text{Ker}(f) + U$.

If $u = a_1u_1 + \dots + a_ru_r \in U$ also belongs to $\text{Ker}(f)$, then

$$0 = f(u) = f(a_1u_1 + \dots + a_ru_r) = a_1v_1 + \dots + a_rv_r,$$

and since (v_1, \dots, v_r) is a basis, $a_i = 0$ for $i = 1, \dots, r$, which shows that $\text{Ker}(f) \cap U = (0)$. Therefore, we have a direct sum

$$E = \text{Ker}(f) \oplus U.$$

Finally, if

$$a_1u_1 + \dots + a_ru_r = 0,$$

the above reasoning shows that $a_i = 0$ for $i = 1, \dots, r$, so (u_1, \dots, u_r) are linearly independent. Therefore, the module U is a free module. \square

One should be aware that if we have a direct sum of modules

$$U = U_1 \oplus \dots \oplus U_m,$$

every vector $u \in U$ can be written in a unique way as

$$u = u_1 + \dots + u_m,$$

with $u_i \in U_i$ but, unlike the case of vector spaces, this does not imply that any m nonzero vectors (u_1, \dots, u_m) are linearly independent. For example, we have the direct sum

$$\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}$$

where $\mathbb{Z}/2\mathbb{Z}$ is viewed as a \mathbb{Z} -module, but $(1, 0)$ and $(0, 1)$ are not linearly independent, since

$$2(1, 0) + 2(0, 1) = (0, 0).$$

A useful fact is that every module is a quotient of some free module. Indeed, if M is an A -module, pick any spanning set I for M (such a set exists, for example, $I = M$), and consider the unique homomorphism $\varphi: A^{(I)} \rightarrow M$ extending the identity function from I to itself. Then we have an isomorphism $A^{(I)}/\text{Ker}(\varphi) \approx M$.

In particular, if M is finitely generated, we can pick I to be a finite set of generators, in which case we get an isomorphism $A^n/\text{Ker}(\varphi) \approx M$, for some natural number n . A finitely generated module is sometimes called a module of *finite type*.

The case $n = 1$ is of particular interest. A module M is said to be *cyclic* if it is generated by a single element. In this case $M = Ax$, for some $x \in M$. We have the linear map $m_x: A \rightarrow M$ given by $a \mapsto ax$ for every $a \in A$, and it is obviously surjective since $M = Ax$. Since the kernel $\mathfrak{a} = \text{Ker}(m_x)$ of m_x is an ideal in A , we get an isomorphism $A/\mathfrak{a} \approx Ax$. Conversely, for any ideal \mathfrak{a} of A , if $M = A/\mathfrak{a}$, we see that M is generated by the image x of 1 in M , so M is a cyclic module.

The ideal $\mathfrak{a} = \text{Ker}(m_x)$ is the set of all $a \in A$ such that $ax = 0$. This is called the *annihilator* of x , and it is the special case of the following more general situation.

Definition 35.5. If M is any A -module, for any subset S of M , the set of all $a \in A$ such that $ax = 0$ for all $x \in S$ is called the *annihilator* of S , and it is denoted by $\text{Ann}(S)$. If $S = \{x\}$, we write $\text{Ann}(x)$ instead of $\text{Ann}(\{x\})$. A nonzero element $x \in M$ is called a *torsion element* iff $\text{Ann}(x) \neq (0)$. The set consisting of all torsion elements in M and 0 is denoted by M_{tor} .

It is immediately verified that $\text{Ann}(S)$ is an ideal of A , and by definition,

$$M_{\text{tor}} = \{x \in M \mid (\exists a \in A, a \neq 0)(ax = 0)\}.$$

If a ring has zero divisors, then the set of all torsion elements in an A -module M may not be a submodule of M . For example, if $M = A = \mathbb{Z}/6\mathbb{Z}$, then $M_{\text{tor}} = \{2, 3, 4\}$, but $3 + 4 = 1$ is not a torsion element. Also, a free module may not be torsion-free because there may be torsion elements, as the example of $\mathbb{Z}/6\mathbb{Z}$ as a free module over itself shows.

However, if A is an integral domain, then a free module is torsion-free and M_{tor} is a submodule of M . (Recall that an integral domain is commutative).

Proposition 35.3. *If A is an integral domain, then for any A -module M , the set M_{tor} of torsion elements in M is a submodule of M .*

Proof. If $x, y \in M$ are torsion elements ($x, y \neq 0$), then there exist some nonzero elements $a, b \in A$ such that $ax = 0$ and $by = 0$. Since A is an integral domain, $ab \neq 0$, and then for all $\lambda, \mu \in A$, we have

$$ab(\lambda x + \mu y) = b\lambda ax + a\mu by = 0.$$

Therefore, M_{tor} is a submodule of M . \square

The module M_{tor} is called the *torsion submodule* of M . If $M_{\text{tor}} = (0)$, then we say that M is *torsion-free*, and if $M = M_{\text{tor}}$, then we say that M is a *torsion module*.

If M is not finitely generated, then it is possible that $M_{\text{tor}} \neq 0$, yet the annihilator of M_{tor} is reduced to 0. For example, let take the \mathbb{Z} -module

$$\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z} \times \cdots \times \mathbb{Z}/p\mathbb{Z} \times \cdots,$$

where p ranges over the set of primes. Call this module M and the set of primes P . Observe that M is generated by $\{\alpha_p\}_{p \in P}$, where α_p is the tuple whose only nonzero entry is $\bar{1}_p$, the generator of $\mathbb{Z}/p\mathbb{Z}$, i.e.,

$$\alpha_p = (\bar{0}, \bar{0}, \bar{0}, \dots, \bar{1}_p, \bar{0}, \dots), \quad \mathbb{Z}/p\mathbb{Z} = \{n \cdot \bar{1}_p\}_{n=0}^{p-1}.$$

In other words, M is not finitely generated. Furthermore, since $p \cdot \bar{1}_p = \bar{0}$, we have $\{\alpha_p\}_{p \in P} \subset M_{\text{tor}}$. However, because p ranges over all primes, the only possible nonzero annihilator of $\{\alpha_p\}_{p \in P}$ would be the product of all the primes. Hence $\text{Ann}(\{\alpha_p\}_{p \in P}) = (0)$. Because of the subset containment, we conclude that $\text{Ann}(M_{\text{tor}}) = (0)$.

However, if M is finitely generated, it is *not* possible that $M_{\text{tor}} \neq 0$, yet the annihilator of M_{tor} is reduced to 0, since if x_1, \dots, x_n generate M and if a_1, \dots, a_n annihilate x_1, \dots, x_n , then $a_1 \cdots a_n$ annihilates every element of M .

Proposition 35.4. *If A is an integral domain, then for any A -module M , the quotient module M/M_{tor} is torsion free.*

Proof. Let \bar{x} be an element of M/M_{tor} and assume that $a\bar{x} = 0$ for some $a \neq 0$ in A . This means that $ax \in M_{\text{tor}}$, so there is some $b \neq 0$ in A such that $bax = 0$. Since $a, b \neq 0$ and A is an integral domain, $ba \neq 0$, so $x \in M_{\text{tor}}$, which means that $\bar{x} = 0$. \square

If A is an integral domain and if F is a free A -module with basis (u_1, \dots, u_n) , then F can be embedded in a K -vector space F_K isomorphic to K^n , where $K = \text{Frac}(A)$ is the fraction field of A . Similarly, any submodule M of F is embedded into a subspace M_K of F_K . Note that any linearly independent vectors (u_1, \dots, u_m) in the A -module M remain linearly independent in the vector space M_K , because any linear dependence over K is of the form

$$\frac{a_1}{b_1} u_1 + \cdots + \frac{a_m}{b_m} u_m = 0$$

for some $a_i, b_i \in A$, with $b_1 \cdots b_m \neq 0$, so if we multiply by $b_1 \cdots b_m \neq 0$, we get a linear dependence in the A -module M . Then we see that the maximum number of linearly independent vectors in the A -module M is at most n . The maximum number of linearly independent vectors in a finitely generated submodule of a free module (over an integral domain) is called the *rank* of the module M . If (u_1, \dots, u_m) are linearly independent where

m is the rank of m , then for every nonzero $v \in M$, there are some $a, a_1, \dots, a_m \in A$, not all zero, such that

$$av = a_1u_1 + \cdots + a_mu_m.$$

We must have $a \neq 0$, since otherwise, linear independence of the u_i would imply that $a_1 = \cdots = a_m = 0$, contradicting the fact that $a, a_1, \dots, a_m \in A$ are not all zero.

Unfortunately, in general, a torsion-free module is not free. For example, \mathbb{Q} as a \mathbb{Z} -module is torsion-free but not free. If we restrict ourselves to finitely generated modules over PID's, then such modules split as the direct sum of their torsion module with a free module, and a torsion module has a nice decomposition in terms of cyclic modules.

The following proposition shows that over a PID, submodules of a free module are free. There are various ways of proving this result. We give a proof due to Lang [109] (see Chapter III, Section 7).

Proposition 35.5. *If A is a PID and if F is a free A -module of dimension n , then every submodule M of F is a free module of dimension at most n .*

Proof. Let (u_1, \dots, u_n) be a basis of F , and let $M_r = M \cap (Au_1 \oplus \cdots \oplus Au_r)$, the intersection of M with the free module generated by (u_1, \dots, u_r) , for $r = 1, \dots, n$. We prove by induction on r that each M_r is free and of dimension at most r . Since $M = M_r$ for some r , this will prove our result.

Consider $M_1 = M \cap Au_1$. If $M_1 = (0)$, we are done. Otherwise let

$$\mathfrak{a} = \{a \in A \mid au_1 \in M\}.$$

It is immediately verified that \mathfrak{a} is an ideal, and since A is a PID, $\mathfrak{a} = a_1A$, for some $a_1 \in A$. Since we are assuming that $M_1 \neq (0)$, we have $a_1 \neq 0$, and $a_1u_1 \in M$. If $x \in M_1$, then $x = au_1$ for some $a \in A$, so $a \in a_1A$, and thus $a = ba_1$ for some $b \in A$. It follows that $M_1 = Aa_1u_1$, which is free.

Assume inductively that M_r is free of dimension at most $r < n$, and let

$$\mathfrak{a} = \{a \in A \mid (\exists b_1 \in A) \cdots (\exists b_r \in A)(b_1u_1 + \cdots + b_ru_r + au_{r+1} \in M)\}.$$

It is immediately verified that \mathfrak{a} is an ideal, and since A is a PID, $\mathfrak{a} = a_{r+1}A$, for some $a_{r+1} \in A$. If $a_{r+1} = 0$, then $M_{r+1} = M_r$, and we are done.

If $a_{r+1} \neq 0$, then there is some $v_1 \in Au_1 \oplus \cdots \oplus Au_r$ such that

$$w = v_1 + a_{r+1}u_{r+1} \in M.$$

For any $x \in M_{r+1}$, there is some $v \in Au_1 \oplus \cdots \oplus Au_r$ and some $a \in A$ such that $x = v + au_{r+1}$. Then, $a \in a_{r+1}A$, so there is some $b \in A$ such that $a = ba_{r+1}$. As a consequence

$$x - bw = v - bv_1 \in M_r,$$

and so $x = x - bw + bw$ with $x - bw \in M_r$, which shows that

$$M_{r+1} = M_r + Aw.$$

On the other hand, if $u \in M_r \cap Aw$, then since $w = v_1 + a_{r+1}u_{r+1}$ we have

$$u = bv_1 + ba_{r+1}u_{r+1},$$

for some $b \in A$, with $u, v_1 \in Au_1 \oplus \cdots \oplus Au_r$, and if $b \neq 0$, this yields the nontrivial linear combination

$$bv_1 - u + ba_{r+1}u_{r+1} = 0,$$

contradicting the fact that (u_1, \dots, u_{r+1}) are linearly independent. Therefore,

$$M_{r+1} = M_r \oplus Aw,$$

which shows that M_{r+1} is free of dimension at most $r + 1$. \square

The following two examples show why the hypothesis of Proposition 35.5 requires A to be PID. First consider $6\mathbb{Z} = \{\bar{0}, \bar{1}, \bar{2}, \bar{3}, \bar{4}, \bar{5}\}$ as a free $6\mathbb{Z}$ -module with generator $\bar{1}$. The $6\mathbb{Z}$ -submodule $\{\bar{0}, \bar{2}, \bar{4}\}$ is not free, even though it is generated by $\bar{2}$ since $\bar{3} \cdot \bar{2} = \bar{0}$. Proposition 35.5 fails since $6\mathbb{Z}$ is not even an integral domain. Next consider $\mathbb{Z}[X]$ as a free $\mathbb{Z}[X]$ -module with generator 1. We claim the ideal

$$(2, X) = \{2p(X) + Xq(X) \mid p(X), q(X) \in \mathbb{Z}[X]\},$$

is not a free $\mathbb{Z}[X]$ -module. Indeed any two nonzero elements of $(2, X)$, say $s(X)$ and $t(X)$, are linearly dependent since $t(X)s(X) - s(X)t(X) = 0$. Once again Proposition 35.5 fails since $\mathbb{Z}[X]$ is not a PID. See Example 32.1.

Proposition 35.5 implies that if M is a finitely generated module over a PID, then any submodule N of M is also finitely generated.

Indeed, if (u_1, \dots, u_n) generate M , then we have a surjection $\varphi: A^n \rightarrow M$ from the free module A^n onto M . The inverse image $\varphi^{-1}(N)$ of N is a submodule of the free module A^n , therefore by Proposition 35.5, $\varphi^{-1}(N)$ is free and finitely generated. This implies that N is finitely generated (and that it has a number of generators $\leq n$).

We can also prove that a finitely generated torsion-free module over a PID is actually free. We will give another proof of this fact later, but the following proof is instructive.

Proposition 35.6. *If A is a PID and if M is a finitely generated module which is torsion-free, then M is free.*

Proof. Let (y_1, \dots, y_n) be some generators for M , and let (u_1, \dots, u_m) be a maximal subsequence of (y_1, \dots, y_n) which is linearly independent. If $m = n$, we are done. Otherwise, due to the maximality of m , for $i = 1, \dots, n$, there is some $a_i \neq 0$ such that such that

$a_i y_i$ can be expressed as a linear combination of (u_1, \dots, u_m) . If we let $a = a_1 \dots a_n$, then $a_1 \dots a_n y_i \in Au_1 \oplus \dots \oplus Au_m$ for $i = 1, \dots, n$, which shows that

$$aM \subseteq Au_1 \oplus \dots \oplus Au_m.$$

Now, A is an integral domain, and since $a_i \neq 0$ for $i = 1, \dots, n$, we have $a = a_1 \dots a_n \neq 0$, and because M is torsion-free, the map $x \mapsto ax$ is injective. It follows that M is isomorphic to a submodule of the free module $Au_1 \oplus \dots \oplus Au_m$. By Proposition 35.5, this submodule is free, and thus, M is free. \square

Although we will obtain this result as a corollary of the structure theorem for finitely generated modules over a PID, we are in the position to give a quick proof of the following theorem.

Theorem 35.7. *Let M be a finitely generated module over a PID. Then M/M_{tor} is free, and there exists a free submodule F of M such that M is the direct sum*

$$M = M_{\text{tor}} \oplus F.$$

The dimension of F is uniquely determined.

Proof. By Proposition 35.4 M/M_{tor} is torsion-free, and since M is finitely generated, it is also finitely generated. By Proposition 35.6, M/M_{tor} is free. We have the quotient linear map $\pi: M \rightarrow M/M_{\text{tor}}$, which is surjective, and M/M_{tor} is free, so by Proposition 35.2, there is a free module F isomorphic to M/M_{tor} such that

$$M = \text{Ker}(\pi) \oplus F = M_{\text{tor}} \oplus F.$$

Since F is isomorphic to M/M_{tor} , the dimension of F is uniquely determined. \square

Theorem 35.7 reduces the study of finitely generated module over a PID to the study of finitely generated torsion modules. This is the path followed by Lang [109] (Chapter III, section 7).

35.2 Finite Presentations of Modules

Since modules are generally not free, it is natural to look for techniques for dealing with nonfree modules. The hint is that if M is an A -module and if $(u_i)_{i \in I}$ is any set of generators for M , then we know that there is a surjective homomorphism $\varphi: A^{(I)} \rightarrow M$ from the free module $A^{(I)}$ generated by I onto M . Furthermore M is isomorphic to $A^{(I)}/\text{Ker}(\varphi)$. Then, we can pick a set of generators $(v_j)_{j \in J}$ for $\text{Ker}(\varphi)$, and again there is a surjective map $\psi: A^{(J)} \rightarrow \text{Ker}(\varphi)$ from the free module $A^{(J)}$ generated by J onto $\text{Ker}(\varphi)$. The map ψ can be viewed as a linear map from $A^{(J)}$ to $A^{(I)}$, we have

$$\text{Im}(\psi) = \text{Ker}(\varphi),$$

and φ is surjective. Note that M is isomorphic to $A^{(I)}/\text{Im}(\psi)$. In such a situation we say that we have an *exact sequence* and this is denoted by the diagram

$$A^{(J)} \xrightarrow{\psi} A^{(I)} \xrightarrow{\varphi} M \longrightarrow 0.$$

Definition 35.6. Given an A -module M , a *presentation* of M is an exact sequence

$$A^{(J)} \xrightarrow{\psi} A^{(I)} \xrightarrow{\varphi} M \longrightarrow 0$$

which means that

1. $\text{Im}(\psi) = \text{Ker}(\varphi)$.
2. φ is surjective.

Consequently, M is isomorphic to $A^{(I)}/\text{Im}(\psi)$. If I and J are both finite, we say that this is a *finite presentation* of M .

Observe that in the case of a finite presentation, I and J are finite, and if $|J| = n$ and $|I| = m$, then ψ is a linear map $\psi: A^n \rightarrow A^m$, so it is given by some $m \times n$ matrix R with coefficients in A called the *presentation matrix* of M . Every column R^j of R may thought of as a relation

$$a_{j1}e_1 + \cdots + a_{jm}e_m = 0$$

among the generators e_1, \dots, e_m of A^m , so we have n relations among these generators. Also the images of e_1, \dots, e_m in M are generators of M , so we can think of the above relations as relations among the generators of M .

The submodule of A^m spanned by the columns of R is the *set of relations* of M , and the columns of R are called a *complete set of relations* for M . The vectors e_1, \dots, e_m are called a set of *generators* for M . We may also say that the generators e_1, \dots, e_m and the relations R^1, \dots, R^n (the columns of R) are a (finite) presentation of the module M . The *module M presented by R is isomorphic to A^m/RA^n* , where we denote by RA^n the image of A^n by the linear map defined by R .

For example, the \mathbb{Z} -module presented by the 1×1 matrix $R = (5)$ is the quotient, $\mathbb{Z}/5\mathbb{Z}$, of \mathbb{Z} by the submodule $5\mathbb{Z}$ corresponding to the single relation

$$5e_1 = 0.$$

But $\mathbb{Z}/5\mathbb{Z}$ has other presentations. For example, if we consider the matrix of relations

$$R = \begin{pmatrix} 2 & -1 \\ 1 & 2 \end{pmatrix},$$

presenting the module M , then we have the relations

$$\begin{aligned} 2e_1 + e_2 &= 0 \\ -e_1 + 2e_2 &= 0. \end{aligned}$$

From the first equation, we get $e_2 = -2e_1$, and substituting into the second equation we get

$$-5e_1 = 0.$$

It follows that the generator e_2 can be eliminated and M is generated by the single generator e_1 satisfying the relation

$$5e_1 = 0,$$

which shows that $M \approx \mathbb{Z}/5\mathbb{Z}$.

The above example shows that many different matrices can present the same module. Here are some useful rules for manipulating a relation matrix without changing the isomorphism class of the module M it presents.

Proposition 35.8. *If R is an $m \times n$ matrix presenting an A -module M , then the matrices S of the form listed below present the same module (a module isomorphic to M):*

- (1) $S = QRP^{-1}$, where Q is a $m \times m$ invertible matrix and P a $n \times n$ invertible matrix (both over A).
- (2) S is obtained from R by deleting a column of zeros.
- (3) The j th column of R is e_i , and S is obtained from R by deleting the i th row and the j th column.

Proof. (1) By definition, we have an isomorphism $M \approx A^m / RA^n$, where we denote by RA^n the image of A^n by the linear map defined by R . Going from R to QRP^{-1} corresponds to making a change of basis in A^m and a change of basis in A^n , and this yields a quotient module isomorphic to M .

(2) A zero column does not contribute to the span of the columns of R , so it can be eliminated.

(3) If the j th column of R is e_i , then when taking the quotient A^m / RA^n , the generator e_i goes to zero. This means that the generator e_i is redundant, and when we delete it, we get a matrix of relations in which the i th row of R and the j th column of R are deleted. \square

The matrices P and Q are often products of elementary operations. One should be careful that rows of zeros cannot be eliminated. For example, the 2×1 matrix

$$R_1 = \begin{pmatrix} 4 \\ 0 \end{pmatrix}$$

gives the single relation

$$4e_1 = 0,$$

but the second generator e_2 cannot be eliminated. This matrix presents the module $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}$. On the other hand, the 1×2 matrix

$$R_2 = (4 \ 0)$$

gives two relations

$$\begin{aligned} 4e_1 &= 0, \\ 0 &= 0, \end{aligned}$$

so the second generator can be eliminated and R_2 presents the module $\mathbb{Z}/4\mathbb{Z}$.

The rules of Proposition 35.8 make it possible to simplify a presentation matrix quite a lot in some cases. For example, consider the relation matrix

$$R = \begin{pmatrix} 3 & 8 & 7 & 9 \\ 2 & 4 & 6 & 6 \\ 1 & 2 & 2 & 1 \end{pmatrix}.$$

By subtracting 2 times row 3 from row 2 and subtracting 3 times row 3 from row 1, we get

$$\begin{pmatrix} 0 & 2 & 1 & 6 \\ 0 & 0 & 2 & 4 \\ 1 & 2 & 2 & 1 \end{pmatrix}.$$

After deleting column 1 and row 3, we get

$$\begin{pmatrix} 2 & 1 & 6 \\ 0 & 2 & 4 \end{pmatrix}.$$

By subtracting 2 times row 1 from row 2, we get

$$\begin{pmatrix} 2 & 1 & 6 \\ -4 & 0 & -8 \end{pmatrix}.$$

After deleting column 2 and row 1, we get

$$(-4 \ -8).$$

By subtracting 2 times column 1 from column 2, we get

$$(-4 \ 0).$$

Finally, we can drop the second column and we get

$$(4),$$

which shows that R presents the module $\mathbb{Z}/4\mathbb{Z}$.

Unfortunately a submodule of a free module of finite dimension is not necessarily finitely generated but, by Proposition 35.5, if A is a PID, then any submodule of a finitely generated module is finitely generated. This property actually characterizes Noetherian rings. To prove it, we need a slightly different version of Proposition 35.2.

Proposition 35.9. *Let $f: E \rightarrow F$ be a linear map between two A -modules E and F .*

- (1) *Given any set of generators (v_1, \dots, v_r) of $\text{Im}(f)$, for any r vectors $u_1, \dots, u_r \in E$ such that $f(u_i) = v_i$ for $i = 1, \dots, r$, if U is the finitely generated submodule of E generated by (u_1, \dots, u_r) , then the module E is the sum*

$$E = \text{Ker}(f) + U.$$

Consequently, if both $\text{Ker}(f)$ and $\text{Im}(f)$ are finitely generated, then E is finitely generated.

- (2) *If E is finitely generated, then so is $\text{Im}(f)$.*

Proof. (1) Pick any $w \in E$, write $f(w)$ over the generators (v_1, \dots, v_r) of $\text{Im}(f)$ as $f(w) = a_1v_1 + \dots + a_rv_r$, and let $u = a_1u_1 + \dots + a_ru_r$. Observe that

$$\begin{aligned} f(w - u) &= f(w) - f(u) \\ &= a_1v_1 + \dots + a_rv_r - (a_1f(u_1) + \dots + a_rf(u_r)) \\ &= a_1v_1 + \dots + a_rv_r - (a_1v_1 + \dots + a_rv_r) \\ &= 0. \end{aligned}$$

Therefore, $h = w - u \in \text{Ker}(f)$, and since $w = h + u$ with $h \in \text{Ker}(f)$ and $u \in U$, we have $E = \text{Ker}(f) + U$, as claimed. If $\text{Ker}(f)$ is also finitely generated, by taking the union of a finite set of generators for $\text{Ker}(f)$ and (v_1, \dots, v_r) , we obtain a finite set of generators for E .

- (2) If (u_1, \dots, u_n) generate E , it is obvious that $(f(u_1), \dots, f(u_n))$ generate $\text{Im}(f)$. \square

Theorem 35.10. *A ring A is Noetherian iff every submodule N of a finitely generated A -module M is itself finitely generated.*

Proof. First, assume that every submodule N of a finitely generated A -module M is itself finitely generated. The ring A is a module over itself and it is generated by the single element 1. Furthermore, every submodule of A is an ideal, so the hypothesis implies that every ideal in A is finitely generated, which shows that A is Noetherian.

Now, assume A is Noetherian. First, observe that it is enough to prove the theorem for the finitely generated free modules A^n (with $n \geq 1$). Indeed, assume that we proved for every $n \geq 1$ that every submodule of A^n is finitely generated. If M is any finitely generated A -module, then there is a surjection $\varphi: A^n \rightarrow M$ for some n (where n is the number of elements of a finite generating set for M). Given any submodule N of M , $L = \varphi^{-1}(N)$ is a

submodule of A^n . Since A^n is finitely generated, the submodule N of A^n is finitely generated, and then $N = \varphi(L)$ is finitely generated.

It remains to prove the theorem for $M = A^n$. We proceed by induction on n . For $n = 1$, a submodule N of A is an ideal, and since A is Noetherian, N is finitely generated. For the induction step where $n > 1$, consider the projection $\pi: A^n \rightarrow A^{n-1}$ given by

$$\pi(a_1, \dots, a_n) = (a_1, \dots, a_{n-1}).$$

The kernel of π is the module

$$\text{Ker}(\pi) = \{(0, \dots, 0, a_n) \in A^n \mid a_n \in A\} \approx A.$$

For any submodule N of A^n , let $\varphi: N \rightarrow A^{n-1}$ be the restriction of π to N . Since $\varphi(N)$ is a submodule of A^{n-1} , by the induction hypothesis, $\text{Im}(\varphi) = \varphi(N)$ is finitely generated. Also, $\text{Ker}(\varphi) = N \cap \text{Ker}(\pi)$ is a submodule of $\text{Ker}(\pi) \approx A$, and thus $\text{Ker}(\varphi)$ is isomorphic to an ideal of A , and thus is finitely generated (since A is Noetherian). Since both $\text{Im}(\varphi)$ and $\text{Ker}(\varphi)$ are finitely generated, by Proposition 35.9, the submodule N is also finitely generated. \square

As a consequence of Theorem 35.10, every finitely generated A -module over a Noetherian ring A is finitely presented, because if $\varphi: A^n \rightarrow M$ is a surjection onto the finitely generated module M , then $\text{Ker}(\varphi)$ is finitely generated. In particular, if A is a PID, then every finitely generated module is finitely presented.

If the ring A is not Noetherian, then there exist finitely generated A -modules that are not finitely presented. This is not so easy to prove.

We will prove in Proposition 35.35 that if A is a PID then a matrix R can “diagonalized” as

$$R = QDP^{-1}$$

where D is a diagonal matrix (more computational versions of this proposition are given in Theorem 36.18 and Theorem 36.21). It follows from Proposition 35.8 that every finitely generated module M over a PID has a presentation with m generators and r relations of the form

$$\alpha_i e_i = 0,$$

where $\alpha_i \neq 0$ and $\alpha_1 \mid \alpha_2 \mid \dots \mid \alpha_r$, which shows that M is isomorphic to the direct sum

$$M \approx A^{m-r} \oplus A/(\alpha_1 A) \oplus \dots \oplus A/(\alpha_r A).$$

This is a version of Theorem 35.25 that will be proved in Section 35.5.

35.3 Tensor Products of Modules over a Commutative Ring

It is possible to define tensor products of modules over a ring, just as in Section 33.2, and the results of this section continue to hold. The results of Section 33.4 also continue to hold since they are based on the universal mapping property. However, the results of Section 33.3 on bases generally fail, except for free modules. Similarly, the results of Section 33.5 on duality generally fail. Tensor algebras can be defined for modules, as in Section 33.6. Symmetric tensor and alternating tensors can be defined for modules but again, results involving bases generally fail.

Tensor products of modules have some unexpected properties. For example, if p and q are relatively prime integers, then

$$\mathbb{Z}/p\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/q\mathbb{Z} = (0).$$

This is because, by Bezout's identity, there are $a, b \in \mathbb{Z}$ such that

$$ap + bq = 1,$$

so, for all $x \in \mathbb{Z}/p\mathbb{Z}$ and all $y \in \mathbb{Z}/q\mathbb{Z}$, we have

$$\begin{aligned} x \otimes y &= ap(x \otimes y) + bq(x \otimes y) \\ &= a(px \otimes y) + b(x \otimes qy) \\ &= a(0 \otimes y) + b(x \otimes 0) \\ &= 0. \end{aligned}$$

It is possible to salvage certain properties of tensor products holding for vector spaces by restricting the class of modules under consideration. For example, *projective modules* have a pretty good behavior w.r.t. tensor products.

A free A -module F , is a module that has a basis (*i.e.*, there is a family, $(e_i)_{i \in I}$, of linearly independent vectors in F that span F). Projective modules have many equivalent characterizations. Here is one that is best suited for our needs:

Definition 35.7. An A -module, P , is *projective* if it is a summand of a free module, that is, if there is a free A -module, F , and some A -module, Q , so that

$$F = P \oplus Q.$$

Given any A -module, M , we let $M^* = \text{Hom}_A(M, A)$ be its *dual*. We have the following proposition:

Proposition 35.11. *For any finitely-generated projective A -modules, P , and any A -module, Q , we have the isomorphisms:*

$$\begin{aligned} P^{**} &\cong P \\ \text{Hom}_A(P, Q) &\cong P^* \otimes_A Q. \end{aligned}$$

Proof sketch. We only consider the second isomorphism. Since P is projective, we have some A -modules, P_1, F , with

$$P \oplus P_1 = F,$$

where F is some free module. Now, we know that for any A -modules, U, V, W , we have

$$\text{Hom}_A(U \oplus V, W) \cong \text{Hom}_A(U, W) \prod \text{Hom}_A(V, W) \cong \text{Hom}_A(U, W) \oplus \text{Hom}_A(V, W),$$

so

$$P^* \oplus P_1^* \cong F^*, \quad \text{Hom}_A(P, Q) \oplus \text{Hom}_A(P_1, Q) \cong \text{Hom}_A(F, Q).$$

By tensoring with Q and using the fact that tensor distributes w.r.t. coproducts, we get

$$(P^* \otimes_A Q) \oplus (P_1^* \otimes_A Q) \cong (P^* \oplus P_1^*) \otimes_A Q \cong F^* \otimes_A Q.$$

Now, the proof of Proposition 33.17 goes through because F is free and finitely generated, so

$$\alpha_{\otimes}: (P^* \otimes_A Q) \oplus (P_1^* \otimes_A Q) \cong F^* \otimes_A Q \longrightarrow \text{Hom}_A(F, Q) \cong \text{Hom}_A(P, Q) \oplus \text{Hom}_A(P_1, Q)$$

is an isomorphism and as α_{\otimes} maps $P^* \otimes_A Q$ to $\text{Hom}_A(P, Q)$, it yields an isomorphism between these two spaces. \square

The isomorphism $\alpha_{\otimes}: P^* \otimes_A Q \cong \text{Hom}_A(P, Q)$ of Proposition 35.11 is still given by

$$\alpha_{\otimes}(u^* \otimes f)(x) = u^*(x)f, \quad u^* \in P^*, f \in Q, x \in P.$$

It is convenient to introduce the *evaluation map*, $\text{Ev}_x: P^* \otimes_A Q \rightarrow Q$, defined for every $x \in P$ by

$$\text{Ev}_x(u^* \otimes f) = u^*(x)f, \quad u^* \in P^*, f \in Q.$$

We will need the following generalization of part (4) of Proposition 33.13.

Proposition 35.12. *Given any two families of A -modules $(M_i)_{i \in I}$ and $(N_j)_{j \in J}$ (where I and J are finite index sets), we have an isomorphism*

$$\left(\bigoplus_{i \in I} M_i \right) \otimes \left(\bigoplus_{j \in J} N_j \right) \approx \bigoplus_{(i,j) \in I \times J} (M_i \otimes N_j).$$

Proposition 35.12 also holds for infinite index sets.

Proposition 35.13. *Let M and N be two A -module with N a free module, and pick any basis (v_1, \dots, v_n) for N . Then, every element of $M \otimes N$ can be expressed in a unique way as a sum of the form*

$$u_1 \otimes v_1 + \cdots + u_n \otimes v_n, \quad u_i \in M,$$

so that $M \otimes N$ is isomorphic to M^n (as an A -module).

Proof. Since N is free with basis (v_1, \dots, v_n) , we have an isomorphism

$$N \approx Av_1 \oplus \cdots \oplus Av_n.$$

By Proposition 35.12, we obtain an isomorphism

$$M \otimes N \approx M \otimes (Av_1 \oplus \cdots \oplus Av_n) \approx (M \otimes Av_1) \oplus \cdots \oplus (M \otimes Av_n).$$

Because (v_1, \dots, v_n) is a basis of N , each v_j is torsion-free so the map $a \mapsto av_j$ is an isomorphism of A onto Av_j , and because $M \otimes A \approx M$, we have the isomorphism

$$M \otimes N \approx (M \otimes A) \oplus \cdots \oplus (M \otimes A) \approx M \oplus \cdots \oplus M = M^n,$$

as claimed. \square

Proposition 35.13 also holds for an infinite basis $(v_j)_{j \in J}$ of N . Obviously, a version of Proposition 35.13 also holds if M is free and N is arbitrary.

The next proposition will be also be needed.

Proposition 35.14. *Given any A -module M and any ideal \mathfrak{a} in A , there is an isomorphism*

$$(A/\mathfrak{a}) \otimes_A M \approx M/\mathfrak{a}M$$

given by the map $(\bar{a} \otimes u) \mapsto au \pmod{\mathfrak{a}M}$, for all $\bar{a} \in A/\mathfrak{a}$ and all $u \in M$.

Sketch of proof. Consider the map $\varphi: (A/\mathfrak{a}) \times M \rightarrow M/\mathfrak{a}M$ given by

$$\varphi(\bar{a}, u) = au \pmod{\mathfrak{a}M}$$

for all $\bar{a} \in A/\mathfrak{a}$ and all $u \in M$. It is immediately checked that φ is well-defined because $au \pmod{\mathfrak{a}M}$ does not depend on the representative $a \in A$ chosen in the equivalence class \bar{a} , and φ is bilinear. Therefore, φ induces a linear map $\varphi: (A/\mathfrak{a}) \otimes M \rightarrow M/\mathfrak{a}M$, such that $\varphi(\bar{a} \otimes u) = au \pmod{\mathfrak{a}M}$. We also define the map $\psi: M \rightarrow (A/\mathfrak{a}) \otimes M$ by

$$\psi(u) = \bar{1} \otimes u.$$

Since $\mathfrak{a}M$ is generated by vectors of the form au with $a \in \mathfrak{a}$ and $u \in M$, and since

$$\psi(au) = \bar{1} \otimes au = \bar{a} \otimes u = 0 \otimes u = 0,$$

we see that $\mathfrak{a}M \subseteq \text{Ker } (\psi)$, so ψ induces a linear map $\psi: M/\mathfrak{a}M \rightarrow (A/\mathfrak{a}) \otimes M$. We have

$$\begin{aligned} \psi(\varphi(\bar{a} \otimes u)) &= \psi(au) \\ &= \bar{1} \otimes au \\ &= \bar{a} \otimes u \end{aligned}$$

and

$$\begin{aligned}\varphi(\psi(u)) &= \varphi(\bar{1} \otimes u) \\ &= 1u \\ &= u,\end{aligned}$$

which shows that φ and ψ are mutual inverses. \square

We now develop the theory necessary to understand the structure of finitely generated modules over a PID.

35.4 Torsion Modules over a PID; The Primary Decomposition

We begin by considering modules over a product ring obtained from a direct decomposition, as in Definition 32.3. In this section and the next, we closely follow Bourbaki [26] (Chapter VII). Let A be a commutative ring and let $(\mathfrak{b}_1, \dots, \mathfrak{b}_n)$ be ideals in A such that there is an isomorphism $A \approx A/\mathfrak{b}_1 \times \dots \times A/\mathfrak{b}_n$. From Theorem 32.16 part (b), there exist some elements e_1, \dots, e_n of A such that

$$\begin{aligned}e_i^2 &= e_i \\ e_i e_j &= 0, \quad i \neq j \\ e_1 + \dots + e_n &= 1_A,\end{aligned}$$

and $\mathfrak{b}_i = (1_A - e_i)A$, for $i, j = 1, \dots, n$.

Given an A -module M with $A \approx A/\mathfrak{b}_1 \times \dots \times A/\mathfrak{b}_n$, let M_i be the subset of M annihilated by \mathfrak{b}_i ; that is,

$$M_i = \{x \in M \mid bx = 0, \text{ for all } b \in \mathfrak{b}_i\}.$$

Because \mathfrak{b}_i is an ideal, each M_i is a submodule of M . Observe that if $\lambda, \mu \in A$, $b \in \mathfrak{b}_i$, and if $\lambda - \mu = b$, then for any $x \in M_i$, since $bx = 0$,

$$\lambda x = (\mu + b)x = \mu x + bx = \mu x,$$

so M_i can be viewed as a A/\mathfrak{b}_i -module.

Proposition 35.15. *Given a ring $A \approx A/\mathfrak{b}_1 \times \dots \times A/\mathfrak{b}_n$ as above, the A -module M is the direct sum*

$$M = M_1 \oplus \dots \oplus M_n,$$

where M_i is the submodule of M annihilated by \mathfrak{b}_i .

Proof. For $i = 1, \dots, n$, let $p_i: M \rightarrow M$ be the map given by

$$p_i(x) = e_i x, \quad x \in M.$$

The map p_i is clearly linear, and because of the properties satisfied by the e_i s, we have

$$\begin{aligned} p_i^2 &= p_i \\ p_i p_j &= 0, \quad i \neq j \\ p_1 + \cdots + p_n &= \text{id}. \end{aligned}$$

This shows that the p_i are projections, and by Proposition 6.8 (which also holds for modules), we have a direct sum

$$M = p_1(M) \oplus \cdots \oplus p_n(M) = e_1 M \oplus \cdots \oplus e_n M.$$

It remains to show that $M_i = e_i M$. Since $(1 - e_i)e_i = e_i - e_i^2 = e_i - e_i = 0$, we see that $e_i M$ is annihilated by $\mathfrak{b}_i = (1 - e_i)A$. Furthermore, for $i \neq j$, for any $x \in M$, we have $(1 - e_i)e_j x = (e_j - e_i e_j)x = e_j x$, so no nonzero element of $e_j M$ is annihilated by $1 - e_i$, and thus not annihilated by \mathfrak{b}_i . It follows that $e_i M = M_i$, as claimed. \square

Definition 35.8. Given an A -module M , for any nonzero $\alpha \in A$, let

$$M(\alpha) = \{x \in M \mid \alpha x = 0\},$$

the submodule of M annihilated by α . If α divides β , then $M(\alpha) \subseteq M(\beta)$, so we can define

$$M_\alpha = \bigcup_{n \geq 1} M(\alpha^n) = \{x \in M \mid (\exists n \geq 1)(\alpha^n x = 0)\},$$

the submodule of M consisting of all elements of M annihilated by some power of α .

If N is any submodule of M , it is clear that

$$N_\alpha = M \cap M_\alpha.$$

Recall that in a PID, an irreducible element is also called a *prime element*.

Definition 35.9. If A is a PID and p is a prime element in A , we say that a module M is p -primary if $M = M_p$.

Proposition 35.16. Let M be module over a PID A . For every nonzero $\alpha \in A$, if

$$\alpha = u p_1^{n_1} \cdots p_r^{n_r}$$

is a factorization of α into prime factors (where u is a unit), then the module $M(\alpha)$ annihilated by α is the direct sum

$$M(\alpha) = M(p_1^{n_1}) \oplus \cdots \oplus M(p_r^{n_r}).$$

Furthermore, the projection from $M(\alpha)$ onto $M(p_i^{n_i})$ is of the form $x \mapsto \gamma_i x$, for some $\gamma_i \in A$, and

$$M(p_i^{n_i}) = M(\alpha) \cap M_{p_i}.$$

Proof. First observe that since $M(\alpha)$ is annihilated by α , we can view $M(\alpha)$ as a $A/(\alpha)$ -module. By the Chinese remainder theorem (Theorem 32.15) applied to the ideals $(up_1^{n_1}) = (p_1^{n_1}), (p_2^{n_2}), \dots, (p_r^{n_r})$, we have an isomorphism

$$A/(\alpha) \approx A/(p_1^{n_1}) \times \cdots \times A/(p_r^{n_r}).$$

Since we also have isomorphisms

$$A/(p_i^{n_i}) \approx (A/(\alpha))/((p_i^{n_i})/(\alpha)),$$

we can apply Proposition 35.15, and we get a direct sum

$$M(\alpha) = N_1 \oplus \cdots \oplus N_r,$$

where N_i is the $A/(\alpha)$ -submodule of $M(\alpha)$ annihilated by $(p_i^{n_i})/(\alpha)$, and the projections onto the N_i are of the form stated in the proposition. However, N_i is just the A -module $M(p_i^{n_i})$ annihilated by $p_i^{n_i}$, because every nonzero element of $(p_i^{n_i})/(\alpha)$ is an equivalence class modulo (α) of the form $ap_i^{n_i}$ for some nonzero $a \in A$, and by definition, $x \in N_i$ iff

$$0 = \overline{ap_i^{n_i}} x = ap_i^{n_i} x, \quad \text{for all } a \in A - \{0\},$$

in particular for $a = 1$, which implies that $x \in M(p_i^{n_i})$.

The inclusion $M(p_i^{n_i}) \subseteq M(\alpha) \cap M_{p_i}$ is clear. Conversely, pick $x \in M(\alpha) \cap M_{p_i}$, which means that $\alpha x = 0$ and $p_i^s x = 0$ for some $s \geq 1$. If $s < n_i$, we are done, so assume $s \geq n_i$. Since $p_i^{n_i}$ is a gcd of α and p_i^s , by Bezout, we can write

$$p_i^{n_i} = \lambda p_i^s + \mu \alpha$$

for some $\lambda, \mu \in A$, and then $p_i^{n_i} x = \lambda p_i^s x + \mu \alpha x = 0$, which shows that $x \in M(p_i^{n_i})$, as desired. \square

Here is an example of Proposition 35.16. Let $M = \mathbb{Z}/60\mathbb{Z}$, where M is considered as a \mathbb{Z} -module. An element in M is denoted by \bar{x} , where x is an integer with $0 \leq x \leq 59$. Let $\alpha = 6$ and define

$$M(6) = \{\bar{x} \in M \mid 6\bar{x} = \bar{0}\} = \{\bar{0}, \bar{10}, \bar{20}, \bar{30}, \bar{40}, \bar{50}\}.$$

Since $6 = 2 \cdot 3$, Proposition 35.16 implies that $M(6) = M(2) \oplus M(3)$, where

$$\begin{aligned} M(2) &= \{\bar{x} \in M \mid 2\bar{x} = \bar{0}\} = \{\bar{0}, \bar{30}\} \\ M(3) &= \{\bar{x} \in M \mid 3\bar{x} = \bar{0}\} = \{\bar{0}, \bar{20}, \bar{40}\}. \end{aligned}$$

Recall that if M is a torsion module over a ring A which is an integral domain, then every finite set of elements x_1, \dots, x_n in M is annihilated by $a = a_1 \cdots a_n$, where each a_i annihilates x_i .

Since A is a PID, we can pick a set P of irreducible elements of A such that every nonzero nonunit of A has a unique factorization up to a unit. Then, we have the following structure theorem for torsion modules which holds even for modules that are not finitely generated.

Theorem 35.17. (*Primary Decomposition Theorem*) Let M be a torsion-module over a PID. For every irreducible element $p \in P$, let M_p be the submodule of M annihilated by some power of p . Then, M is the (possibly infinite) direct sum

$$M = \bigoplus_{p \in P} M_p.$$

Proof. Since M is a torsion-module, for every $x \in M$, there is some $\alpha \in A$ such that $x \in M(\alpha)$. By Proposition 35.16, if $\alpha = up_1^{n_1} \cdots p_r^{n_r}$ is a factorization of α into prime factors (where u is a unit), then the module $M(\alpha)$ is the direct sum

$$M(\alpha) = M(p_1^{n_1}) \oplus \cdots \oplus M(p_r^{n_r}).$$

This means that x can be written as

$$x = \sum_{p \in P} x_p, \quad x_p \in M_p,$$

with only finitely many x_p nonzero. If

$$\sum_{p \in P} x_p = \sum_{p \in P} y_p$$

for all $p \in P$, with only finitely many x_p and y_p nonzero, then x_p and y_p are annihilated by some common nonzero element $a \in A$, so $x_p, y_p \in M(a)$. By Proposition 35.16, we must have $x_p = y_p$ for all p , which proves that we have a direct sum. \square

It is clear that if p and p' are two irreducible elements such that $p = up'$ for some unit u , then $M_p = M_{p'}$. Therefore, M_p only depends on the ideal (p) .

Definition 35.10. Given a torsion-module M over a PID, the modules M_p associated with irreducible elements in P are called the *p-primary components* of M .

The p -primary components of a torsion module uniquely determine the module, as shown by the next proposition.

Proposition 35.18. Two torsion modules M and N over a PID are isomorphic iff for every every irreducible element $p \in P$, the p -primary components M_p and N_p of M and N are isomorphic.

Proof. Let $f: M \rightarrow N$ be an isomorphism. For any $p \in P$, we have $x \in M_p$ iff $p^k x = 0$ for some $k \geq 1$, so

$$0 = f(p^k x) = p^k f(x),$$

which shows that $f(x) \in N_p$. Therefore, f restricts to a linear map $f \mid M_p$ from M_p to N_p . Since f is an isomorphism, we also have a linear map $f^{-1}: M \rightarrow N$, and our previous

reasoning shows that f^{-1} restricts to a linear map $f^{-1} | N_p$ from N_p to M_p . But, $f | M_p$ and $f^{-1} | N_p$ are mutual inverses, so M_p and N_p are isomorphic.

Conversely, if $M_p \approx N_p$ for all $p \in P$, by Theorem 35.17, we get an isomorphism between $M = \bigoplus_{p \in P} M_p$ and $N = \bigoplus_{p \in P} N_p$. \square

In view of Proposition 35.18, the direct sum of Theorem 35.17 in terms of its p -primary components is called the *canonical primary decomposition* of M .

If M is a finitely generated torsion-module, then Theorem 35.17 takes the following form.

Theorem 35.19. (*Primary Decomposition Theorem for finitely generated torsion modules*) *Let M be a finitely generated torsion-module over a PID A . If $\text{Ann}(M) = (a)$ and if $a = up_1^{n_1} \cdots p_r^{n_r}$ is a factorization of a into prime factors, then M is the finite direct sum*

$$M = \bigoplus_{i=1}^r M(p_i^{n_i}).$$

Furthermore, the projection of M over $M(p_i^{n_i})$ is of the form $x \mapsto \gamma_i x$, for some $\gamma_i \in A$.

Proof. This is an immediate consequence of Proposition 35.16. \square

Theorem 35.19 applies when $A = \mathbb{Z}$. In this case, M is a finitely generated torsion abelian group, and the theorem says that such a group is the direct sum of a finite number of groups whose elements have order some power of a prime number p . In particular, consider the \mathbb{Z} -module $\mathbb{Z}/10\mathbb{Z}$ where

$$\mathbb{Z}/10\mathbb{Z} = \{\bar{0}, \bar{1}, \bar{2}, \bar{3}, \bar{4}, \bar{5}, \bar{6}, \bar{7}, \bar{8}, \bar{9}\}.$$

Clearly $\mathbb{Z}/10\mathbb{Z}$ is generated by $\bar{1}$ and $\text{Ann}(\mathbb{Z}/10\mathbb{Z}) = 10$. Theorem 35.19 implies that

$$\mathbb{Z}/10\mathbb{Z} = M(2) \oplus M(5),$$

where

$$\begin{aligned} M(2) &= \{\bar{x} \in M \mid 2\bar{x} = \bar{0}\} = \{\bar{0}, \bar{5}\} \\ M(5) &= \{\bar{x} \in M \mid 5\bar{x} = \bar{0}\} = \{\bar{0}, \bar{2}, \bar{4}, \bar{6}, \bar{8}\}. \end{aligned}$$

Theorem 35.17 has several useful corollaries.

Proposition 35.20. *If M is a torsion module over a PID, for every submodule N of M , we have a direct sum*

$$N = \bigoplus_{p \in P} N \cap M_p.$$

Proof. It is easily verified that $N \cap M_p$ is the p -primary component of N . \square

Proposition 35.21. *If M is a torsion module over a PID, a submodule N of M is a direct factor of M iff N_p is a direct factor of M_p for every irreducible element $p \in A$.*

Proof. This is because if N and N' are two submodules of M , we have $M = N \oplus N'$ iff, by Proposition 35.20, $M_p = N_p \oplus N'_p$ for every irreducible elements $p \in A$. \square

Definition 35.11. An A -module M is said to be *semi-simple* iff for every submodule N of M , there is some submodule N' of M such that $M = N \oplus N'$.

Proposition 35.22. *Let A be a PID which is not a field, and let M be any A -module. Then M is semi-simple iff it is a torsion module and if $M_p = M(p)$ for every irreducible element $p \in A$ (in other words, if $x \in M$ is annihilated by a power of p , then it is already annihilated by p).*

Proof. Assume that M is semi-simple. Let $x \in M$ and pick any irreducible element $p \in A$. Then, the submodule pAx has a supplement N such that

$$M = pAx \oplus N,$$

so we can write $x = pax + y$, for some $y \in N$ and some $a \in A$. But then,

$$y = (1 - pa)x,$$

and since p is irreducible, p is not a unit, so $1 - pa \neq 0$. Observe that

$$p(1 - ap)x = py \in pAx \cap N = (0).$$

Since $p(1 - ap) \neq 0$, x is a torsion element, and thus M is a torsion module. The above argument shows that

$$p(1 - ap)x = 0,$$

which implies that $px = ap^2x$, and by induction,

$$px = a^n p^{n+1}x, \quad \text{for all } n \geq 1.$$

If we pick x in M_p , then there is some $m \geq 1$ such that $p^m x = 0$, and we conclude that

$$px = 0.$$

Therefore, $M_p = M(p)$, as claimed.

Conversely, assume that M is a torsion-module and that $M_p = M(p)$ for every irreducible element $p \in A$. By Proposition 35.21, it is sufficient to prove that a module annihilated by a an irreducible element is semi-simple. This is because such a module is a vector space over the field $A/(p)$ (recall that in a PID, an ideal (p) is maximal iff p is irreducible), and in a vector space, every subspace has a supplement. \square

Theorem 35.19 shows that a finitely generated torsion module is a direct sum of p -primary modules M_p . We can do better. In the next section we show that each primary module M_p is the direct sum of cyclic modules of the form $A/(p^n)$.

35.5 Finitely Generated Modules over a PID; Invariant Factor Decomposition

There are several ways of obtaining the decomposition of a finitely generated module as a direct sum of cyclic modules. One way to proceed is to first use the Primary Decomposition Theorem and then to show how each primary module M_p is the direct sum of cyclic modules of the form $A/(p^n)$. This is the approach followed by Lang [109] (Chapter III, section 7), among others. We prefer to use a proposition that produces a particular basis for a submodule of a finitely generated free module, because it yields more information. This is the approach followed in Dummitt and Foote [54] (Chapter 12) and Bourbaki [26] (Chapter VII). The proof that we present is due to Pierre Samuel.

Proposition 35.23. *Let F be a finitely generated free module over a PID A , and let M be any submodule of F . Then, M is a free module and there is a basis (e_1, \dots, e_n) of F , some $q \leq n$, and some nonzero elements $a_1, \dots, a_q \in A$, such that $(a_1 e_1, \dots, a_q e_q)$ is a basis of M and a_i divides a_{i+1} for all i , with $1 \leq i \leq q-1$.*

Proof. The proposition is trivial when $M = \{0\}$, thus assume that M is nontrivial. Pick some basis (u_1, \dots, u_n) for F . Let $L(F, A)$ be the set of linear forms on F . For any $f \in L(F, A)$, it is immediately verified that $f(M)$ is an ideal in A . Thus, $f(M) = a_h A$, for some $a_h \in A$, since every ideal in A is a principal ideal. Since A is a PID, any nonempty family of ideals in A has a maximal element, so let f be a linear map such that $a_h A$ is a maximal ideal in A . Let $\pi_i: F \rightarrow A$ be the i -th projection, i.e., π_i is defined such that $\pi_i(x_1 u_1 + \dots + x_n u_n) = x_i$. It is clear that π_i is a linear map, and since M is nontrivial, one of the $\pi_i(M)$ is nontrivial, and $a_h \neq 0$. There is some $e' \in M$ such that $f(e') = a_h$.

We claim that, for every $g \in L(F, A)$, the element $a_h \in A$ divides $g(e')$.

Indeed, if d is the gcd of a_h and $g(e')$, by the Bézout identity, we can write

$$d = ra_h + sg(e'),$$

for some $r, s \in A$, and thus

$$d = rf(e') + sg(e') = (rf + sg)(e').$$

However, $rf + sg \in L(F, A)$, and thus,

$$a_h A \subseteq dA \subseteq (rf + sg)(M),$$

since d divides a_h , and by maximality of $a_h A$, we must have $a_h A = dA$, which implies that $d = a_h$, and thus, a_h divides $g(e')$. In particular, a_h divides each $\pi_i(e')$ and let $\pi_i(e') = a_h b_i$, with $b_i \in A$.

Let $e = b_1 u_1 + \dots + b_n u_n$. Note that

$$e' = \pi_1(e') u_1 + \dots + \pi_n(e') u_n = a_h b_1 u_1 + \dots + a_h b_n u_n,$$

and thus, $e' = a_h e$. Since $a_h = f(e') = f(a_h e) = a_h f(e)$, and since $a_h \neq 0$, we must have $f(e) = 1$.

Next, we claim that

$$F = Ae \oplus f^{-1}(0)$$

and

$$M = Ae' \oplus (M \cap f^{-1}(0)),$$

with $e' = a_h e$.

Indeed, every $x \in F$ can be written as

$$x = f(x)e + (x - f(x)e),$$

and since $f(e) = 1$, we have $f(x - f(x)e) = f(x) - f(x)f(e) = f(x) - f(x) = 0$. Thus, $F = Ae + f^{-1}(0)$. Similarly, for any $x \in M$, we have $f(x) = ra_h$, for some $r \in A$, and thus,

$$x = f(x)e + (x - f(x)e) = ra_h e + (x - f(x)e) = re' + (x - f(x)e),$$

we still have $x - f(x)e \in f^{-1}(0)$, and clearly, $x - f(x)e = x - ra_h e = x - re' \in M$, since $e' \in M$. Thus, $M = Ae' + (M \cap f^{-1}(0))$.

To prove that we have a direct sum, it is enough to prove that $Ae \cap f^{-1}(0) = \{0\}$. For any $x = re \in Ae$, if $f(x) = 0$, then $f(re) = rf(e) = r = 0$, since $f(e) = 1$ and, thus, $x = 0$. Therefore, the sums are direct sums.

We can now prove that M is a free module by induction on the size, q , of a maximal linearly independent family for M .

If $q = 0$, the result is trivial. Otherwise, since

$$M = Ae' \oplus (M \cap f^{-1}(0)),$$

it is clear that $M \cap f^{-1}(0)$ is a submodule of F and that every maximal linearly independent family in $M \cap f^{-1}(0)$ has at most $q - 1$ elements. By the induction hypothesis, $M \cap f^{-1}(0)$ is a free module, and by adding e' to a basis of $M \cap f^{-1}(0)$, we obtain a basis for M , since the sum is direct.

The second part is shown by induction on the dimension n of F .

The case $n = 0$ is trivial. Otherwise, since

$$F = Ae \oplus f^{-1}(0),$$

and since, by the previous argument, $f^{-1}(0)$ is also free, $f^{-1}(0)$ has dimension $n - 1$. By the induction hypothesis applied to its submodule $M \cap f^{-1}(0)$, there is a basis (e_2, \dots, e_n) of $f^{-1}(0)$, some $q \leq n$, and some nonzero elements $a_2, \dots, a_q \in A$, such that, $(a_2 e_2, \dots, a_q e_q)$ is a basis of $M \cap f^{-1}(0)$, and a_i divides a_{i+1} for all i , with $2 \leq i \leq q - 1$. Let $e_1 = e$, and $a_1 = a_h$, as above. It is clear that (e_1, \dots, e_n) is a basis of F , and that that $(a_1 e_1, \dots, a_q e_q)$

is a basis of M , since the sums are direct, and $e' = a_1e_1 = a_h e$. It remains to show that a_1 divides a_2 . Consider the linear map $g: F \rightarrow A$ such that $g(e_1) = g(e_2) = 1$, and $g(e_i) = 0$, for all i , with $3 \leq i \leq n$. We have $a_h = a_1 = g(a_1e_1) = g(e') \in g(M)$, and thus $a_hA \subseteq g(M)$. Since a_hA is maximal, we must have $g(M) = a_hA = a_1A$. Since $a_2 = g(a_2e_2) \in g(M)$, we have $a_2 \in a_1A$, which shows that a_1 divides a_2 . \square

We need the following basic proposition.

Proposition 35.24. *For any commutative ring A , if F is a free A -module and if (e_1, \dots, e_n) is a basis of F , for any elements $a_1, \dots, a_n \in A$, there is an isomorphism*

$$F/(Aa_1e_1 \oplus \dots \oplus Aa_ne_n) \approx (A/a_1A) \oplus \dots \oplus (A/a_nA).$$

Proof. Let $\sigma: F \rightarrow A/(a_1A) \oplus \dots \oplus A/(a_nA)$ be the linear map given by

$$\sigma(x_1e_1 + \dots + x_ne_n) = (\bar{x}_1, \dots, \bar{x}_n),$$

where \bar{x}_i is the equivalence class of x_i in A/a_iA . The map σ is clearly surjective, and its kernel consists of all vectors $x_1e_1 + \dots + x_ne_n$ such that $x_i \in a_iA$, for $i = 1, \dots, n$, which means that

$$\text{Ker } (\sigma) = Aa_1e_1 \oplus \dots \oplus Aa_ne_n.$$

Since $M/\text{Ker } (\sigma)$ is isomorphic to $\text{Im}(\sigma)$, we get the desired isomorphism. \square

We can now prove the existence part of the structure theorem for finitely generated modules over a PID.

Theorem 35.25. *Let M be a finitely generated nontrivial A -module, where A a PID. Then, M is isomorphic to a direct sum of cyclic modules*

$$M \approx A/\mathfrak{a}_1 \oplus \dots \oplus A/\mathfrak{a}_m,$$

where the \mathfrak{a}_i are proper ideals of A (possibly zero) such that

$$\mathfrak{a}_1 \subseteq \mathfrak{a}_2 \subseteq \dots \subseteq \mathfrak{a}_m \neq A.$$

More precisely, if $\mathfrak{a}_1 = \dots = \mathfrak{a}_r = (0)$ and $(0) \neq \mathfrak{a}_{r+1} \subseteq \dots \subseteq \mathfrak{a}_m \neq A$, then

$$M \approx A^r \oplus (A/\mathfrak{a}_{r+1} \oplus \dots \oplus A/\mathfrak{a}_m),$$

where $A/\mathfrak{a}_{r+1} \oplus \dots \oplus A/\mathfrak{a}_m$ is the torsion submodule of M . The module M is free iff $r = m$, and a torsion-module iff $r = 0$. In the latter case, the annihilator of M is \mathfrak{a}_1 .

Proof. Since M is finitely generated and nontrivial, there is a surjective homomorphism $\varphi: A^n \rightarrow M$ for some $n \geq 1$, and M is isomorphic to $A^n/\text{Ker}(\varphi)$. Since $\text{Ker}(\varphi)$ is a submodule of the free module A^n , by Proposition 35.23, $\text{Ker}(\varphi)$ is a free module and there is a basis (e_1, \dots, e_n) of A^n and some nonzero elements a_1, \dots, a_q ($q \leq n$) such that $(a_1 e_1, \dots, a_q e_q)$ is a basis of $\text{Ker}(\varphi)$ and $a_1 \mid a_2 \mid \dots \mid a_q$. Let $a_{q+1} = \dots = a_n = 0$.

By Proposition 35.24, we have an isomorphism

$$A^n/\text{Ker}(\varphi) \approx A/a_1A \oplus \dots \oplus A/a_nA.$$

Whenever a_i is unit, the factor $A/a_iA = (0)$, so we can weed out the units. Let $r = n - q$, and let $s \in \mathbb{N}$ be the smallest index such that a_{s+1} is not a unit. Note that $s = 0$ means that there are no units. Also, as $M \neq (0)$, $s < n$. Then,

$$M \approx A^n/\text{Ker}(\varphi) \approx A/a_{s+1}A \oplus \dots \oplus A/a_nA.$$

Let $m = r + q - s = n - s$. Then, we have the sequence

$$\underbrace{a_{s+1}, \dots, a_q}_{q-s}, \underbrace{a_{q+1}, \dots, a_n}_{r=n-q},$$

where $a_{s+1} \mid a_{s+2} \mid \dots \mid a_q$ are nonzero and nonunits and $a_{q+1} = \dots = a_n = 0$, so we define the m ideals \mathfrak{a}_i as follows:

$$\mathfrak{a}_i = \begin{cases} (0) & \text{if } 1 \leq i \leq r \\ a_{r+q+1-i}A & \text{if } r+1 \leq i \leq m. \end{cases}$$

With these definitions, the ideals \mathfrak{a}_i are proper ideals and we have

$$\mathfrak{a}_i \subseteq \mathfrak{a}_{i+1}, \quad i = 1, \dots, m-1.$$

When $r = 0$, since $a_{s+1} \mid a_{s+2} \mid \dots \mid a_n$, it is clear that $\mathfrak{a}_1 = a_nA$ is the annihilator of M . The other statements of the theorem are clear. \square

Example 35.1. Here is an example of Theorem 35.25. Let M be a \mathbb{Z} -module with generators $\{e_1, e_2, e_3, e_4\}$ subject to the relations $6e_3 = 0$, $2e_4 = 0$. Then

$$M \cong \mathbb{Z} \oplus \mathbb{Z} \oplus \mathbb{Z}/6\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z},$$

where

$$\mathfrak{a}_1 = (0), \quad \mathfrak{a}_2 = (0), \quad \mathfrak{a}_3 = (6), \quad \mathfrak{a}_4 = (2).$$

The natural number r is called the *free rank* or *Betti number* of the module M . The generators $\alpha_1, \dots, \alpha_m$ of the ideals $\mathfrak{a}_1, \dots, \mathfrak{a}_m$ (defined up to a unit) are often called the *invariant factors* of M (in the notation of Theorem 35.25, the generators of the ideals $\mathfrak{a}_1, \dots, \mathfrak{a}_m$ are denoted by a_q, \dots, a_{s+1} , $s \leq q$).

As corollaries of Theorem 35.25, we obtain again the following facts established in Section 35.1:

1. A finitely generated module over a PID is the direct sum of its torsion module and a free module.
2. A finitely generated torsion-free module over a PID is free.

It turns out that the ideals $\mathfrak{a}_1 \subseteq \mathfrak{a}_2 \subseteq \dots \subseteq \mathfrak{a}_m \neq A$ are uniquely determined by the module M . Uniqueness proofs found in most books tend to be intricate and not very intuitive. The shortest proof that we are aware of is from Bourbaki [26] (Chapter VII, Section 4), and uses wedge products.

The following preliminary results are needed.

Proposition 35.26. *If A is a commutative ring and if $\mathfrak{a}_1, \dots, \mathfrak{a}_m$ are ideals of A , then there is an isomorphism*

$$A/\mathfrak{a}_1 \otimes \dots \otimes A/\mathfrak{a}_m \approx A/(\mathfrak{a}_1 + \dots + \mathfrak{a}_m).$$

Sketch of proof. We proceed by induction on m . For $m = 2$, we define the map $\varphi: A/\mathfrak{a}_1 \times A/\mathfrak{a}_2 \rightarrow A/(\mathfrak{a}_1 + \mathfrak{a}_2)$ by

$$\varphi(\bar{a}, \bar{b}) = ab \pmod{\mathfrak{a}_1 + \mathfrak{a}_2}.$$

It is well-defined because if $a' = a + a_1$ and $b' = b + a_2$ with $a_1 \in \mathfrak{a}_1$ and $a_2 \in \mathfrak{a}_2$, then

$$a'b' = (a + a_1)(b + a_2) = ab + ba_1 + aa_2 + a_1a_2,$$

and so

$$a'b' \equiv ab \pmod{\mathfrak{a}_1 + \mathfrak{a}_2}.$$

It is also clear that this map is bilinear, so it induces a linear map $\varphi: A/\mathfrak{a}_1 \otimes A/\mathfrak{a}_2 \rightarrow A/(\mathfrak{a}_1 + \mathfrak{a}_2)$ such that $\varphi(\bar{a} \otimes \bar{b}) = ab \pmod{\mathfrak{a}_1 + \mathfrak{a}_2}$.

Next, observe that any arbitrary tensor

$$\bar{a}_1 \otimes \bar{b}_1 + \dots + \bar{a}_n \otimes \bar{b}_n$$

in $A/\mathfrak{a}_1 \otimes A/\mathfrak{a}_2$ can be rewritten as

$$\bar{1} \otimes (\overline{a_1 b_1} + \dots + \overline{a_n b_n}),$$

which is of the form $\bar{1} \otimes \bar{s}$, with $s \in A$. We can use this fact to show that φ is injective and surjective, and thus an isomorphism.

For example, if $\varphi(\bar{1} \otimes \bar{s}) = 0$, because $\varphi(\bar{1} \otimes \bar{s}) = s \pmod{\mathfrak{a}_1 + \mathfrak{a}_2}$, we have $s \in \mathfrak{a}_1 + \mathfrak{a}_2$, so we can write $s = a + b$ with $a \in \mathfrak{a}_1$ and $b \in \mathfrak{a}_2$. Then

$$\begin{aligned}\bar{1} \otimes \bar{s} &= \bar{1} \otimes \overline{a+b} \\ &= \bar{1} \otimes (\bar{a} + \bar{b}) \\ &= \bar{1} \otimes \bar{a} + \bar{1} \otimes \bar{b} \\ &= \bar{a} \otimes \bar{1} + \bar{1} \otimes \bar{b} \\ &= 0 + 0 = 0,\end{aligned}$$

since $a \in \mathfrak{a}_1$ and $b \in \mathfrak{a}_2$, which proves injectivity. \square

Recall that the exterior algebra of an A -module M is defined by

$$\bigwedge M = \bigoplus_{k \geq 0} \bigwedge^k(M).$$

Proposition 35.27. *If A is a commutative ring, then for any n modules M_i , there is an isomorphism*

$$\bigwedge\left(\bigoplus_{i=1}^n M_i\right) \approx \bigotimes_{i=1}^n \bigwedge M_i.$$

A proof can be found in Bourbaki [25] (Chapter III, Section 7, No 7, Proposition 10).

Proposition 35.28. *Let A be a commutative ring and let $\mathfrak{a}_1, \dots, \mathfrak{a}_n$ be n ideals of A . If the module M is the direct sum of n cyclic modules*

$$M = A/\mathfrak{a}_1 \oplus \cdots \oplus A/\mathfrak{a}_n,$$

then for every $p > 0$, the exterior power $\bigwedge^p M$ is isomorphic to the direct sum of the modules A/\mathfrak{a}_H , where H ranges over all subsets $H \subseteq \{1, \dots, n\}$ with p elements, and with

$$\mathfrak{a}_H = \sum_{h \in H} \mathfrak{a}_h.$$

Proof. If u_i is the image of 1 in A/\mathfrak{a}_i , then A/\mathfrak{a}_i is equal to Au_i . By Proposition 35.27, we have

$$\bigwedge M \approx \bigotimes_{i=1}^n \bigwedge (Au_i).$$

We also have

$$\bigwedge (Au_i) = \bigoplus_{k \geq 0} \bigwedge^k (Au_i) \approx A \oplus Au_i,$$

since $au_i \wedge bu_i = 0$, and it follows that

$$\bigwedge^p M \approx \bigoplus_{\substack{H \subseteq \{1, \dots, n\} \\ H = \{k_1, \dots, k_p\}}} (Au_{k_1}) \otimes \cdots \otimes (Au_{k_p}).$$

However, by Proposition 35.26, we have

$$(Au_{k_1}) \otimes \cdots \otimes (Au_{k_p}) = A/\mathfrak{a}_{k_1} \otimes \cdots \otimes A/\mathfrak{a}_{k_p} \approx A/(\mathfrak{a}_{k_1} + \cdots + \mathfrak{a}_{k_p}) = A/\mathfrak{a}_H.$$

Therefore,

$$\bigwedge^p M \approx \bigoplus_{\substack{H \subseteq \{1, \dots, n\} \\ |H|=p}} A/\mathfrak{a}_H,$$

as claimed. \square

Example 35.1 continued: Recall that M is the \mathbb{Z} -module generated by $\{e_1, e_2, e_3, e_4\}$ subject to $6e_3 = 0$, $2e_2 = 0$. Then

$$\begin{aligned} \bigwedge^1 M &= \text{span}\{e_1, e_2, e_3, e_4\} \\ \bigwedge^2 M &= \text{span}\{e_1 \wedge e_2, e_1 \wedge e_3, e_1 \wedge e_4, e_2 \wedge e_3, e_2 \wedge e_4, e_3 \wedge e_4\} \\ \bigwedge^3 M &= \text{span}\{e_1 \wedge e_2 \wedge e_3, e_1 \wedge e_2 \wedge e_4, e_1 \wedge e_3 \wedge e_4, e_2 \wedge e_3 \wedge e_4\} \\ \bigwedge^4 M &= \text{span}\{e_1 \wedge e_2 \wedge e_3 \wedge e_4\}. \end{aligned}$$

Since $6e_3 = 0$, each element of $\{e_1 \wedge e_3, e_2 \wedge e_3, e_1 \wedge e_2 \wedge e_3\}$ is annihilated by $6\mathbb{Z} = (6)$. Since $2e_2 = 0$, each element of $\{e_1 \wedge e_4, e_2 \wedge e_4, e_3 \wedge e_4, e_1 \wedge e_2 \wedge e_4, e_1 \wedge e_3 \wedge e_4, e_2 \wedge e_3 \wedge e_4, e_1 \wedge e_2 \wedge e_3 \wedge e_4\}$ is annihilated by $2\mathbb{Z} = (2)$. We have shown that

$$M \cong \mathbb{Z} \oplus \mathbb{Z} \oplus \mathbb{Z}/(6) \oplus \mathbb{Z}/(2),$$

where $\mathfrak{a}_1 = (0) = \mathfrak{a}_2$, $\mathfrak{a}_3 = (6)$, and $\mathfrak{a}_4 = (2)$. Then Proposition 35.28 implies that

$$\begin{aligned} \bigwedge^1 M &\cong \mathbb{Z}/\mathfrak{a}_1 \oplus \mathbb{Z}/\mathfrak{a}_2 \oplus \mathbb{Z}/\mathfrak{a}_3 \oplus \mathbb{Z}/\mathfrak{a}_4 = \mathbb{Z} \oplus \mathbb{Z} \oplus \mathbb{Z}/(6) \oplus \mathbb{Z}/(2) \\ \bigwedge^2 M &\cong \mathbb{Z}/(\mathfrak{a}_1 + \mathfrak{a}_2) \oplus \mathbb{Z}/(\mathfrak{a}_1 + \mathfrak{a}_3) \oplus \mathbb{Z}/(\mathfrak{a}_1 + \mathfrak{a}_4) \oplus \mathbb{Z}/(\mathfrak{a}_2 + \mathfrak{a}_3) \oplus \mathbb{Z}/(\mathfrak{a}_2 + \mathfrak{a}_4) \\ &\quad \oplus \mathbb{Z}/(\mathfrak{a}_3 + \mathfrak{a}_4) = \mathbb{Z} \oplus \mathbb{Z}/(6) \oplus \mathbb{Z}/(2) \oplus \mathbb{Z}/(6) \oplus \mathbb{Z}/(2) \oplus \mathbb{Z}/(2) \\ \bigwedge^3 M &\cong \mathbb{Z}/(\mathfrak{a}_1 + \mathfrak{a}_2 + \mathfrak{a}_3) \oplus \mathbb{Z}/(\mathfrak{a}_1 + \mathfrak{a}_2 + \mathfrak{a}_4) \oplus \mathbb{Z}/(\mathfrak{a}_1 + \mathfrak{a}_3 + \mathfrak{a}_4) \oplus \mathbb{Z}/(\mathfrak{a}_1 + \mathfrak{a}_3 + \mathfrak{a}_4) \\ &= \mathbb{Z}/(6) \oplus \mathbb{Z}/(2) \oplus \mathbb{Z}/(2) \oplus \mathbb{Z}/(2) \\ \bigwedge^4 M &\cong \mathbb{Z}/(\mathfrak{a}_1 + \mathfrak{a}_2 + \mathfrak{a}_3 + \mathfrak{a}_4) = \mathbb{Z}/(2). \end{aligned}$$

When the ideals \mathfrak{a}_i form a chain of inclusions $\mathfrak{a}_1 \subseteq \cdots \subseteq \mathfrak{a}_n$, we get the following remarkable result.

Proposition 35.29. *Let A be a commutative ring and let $\mathfrak{a}_1, \dots, \mathfrak{a}_n$ be n ideals of A such that $\mathfrak{a}_1 \subseteq \mathfrak{a}_2 \subseteq \cdots \subseteq \mathfrak{a}_n$. If the module M is the direct sum of n cyclic modules*

$$M = A/\mathfrak{a}_1 \oplus \cdots \oplus A/\mathfrak{a}_n,$$

then for every p with $1 \leq p \leq n$, the ideal \mathfrak{a}_p is the annihilator of the exterior power $\bigwedge^p M$. If $\mathfrak{a}_n \neq A$, then $\bigwedge^p M \neq (0)$ for $p = 1, \dots, n$, and $\bigwedge^p M = (0)$ for $p > n$.

Proof. With the notation of Proposition 35.28, we have $\mathfrak{a}_H = \mathfrak{a}_{\max(H)}$, where $\max(H)$ is the greatest element in the set H . Since $\max(H) \geq p$ for any subset with p elements and since $\max(H) = p$ when $H = \{1, \dots, p\}$, we see that

$$\mathfrak{a}_p = \bigcap_{\substack{H \subseteq \{1, \dots, n\} \\ |H|=p}} \mathfrak{a}_H.$$

By Proposition 35.28, we have

$$\bigwedge^p M \approx \bigoplus_{\substack{H \subseteq \{1, \dots, n\} \\ |H|=p}} A/\mathfrak{a}_H$$

which proves that \mathfrak{a}_p is indeed the annihilator of $\bigwedge^p M$. The rest is clear. \square

Example 35.1 continued: Recall that M is the \mathbb{Z} -module generated by $\{e_1, e_2, e_3, e_4\}$ subject to $6e_3 = 0$, $2e_2 = 0$. Then

$$\begin{aligned} \bigwedge^1 M &= \text{span}\{e_1, e_2, e_3, e_4\} \\ \bigwedge^2 M &= \text{span}\{e_1 \wedge e_2, e_1 \wedge e_3, e_1 \wedge e_4, e_2 \wedge e_3, e_2 \wedge e_4, e_3 \wedge e_4\} \\ \bigwedge^3 M &= \text{span}\{e_1 \wedge e_2 \wedge e_3, e_1 \wedge e_2 \wedge e_4, e_1 \wedge e_3 \wedge e_4, e_2 \wedge e_3 \wedge e_4\} \\ \bigwedge^4 M &= \text{span}\{e_1 \wedge e_2 \wedge e_3 \wedge e_4\}. \end{aligned}$$

Since e_1 and e_2 are free, $e_1 \wedge e_2$ is also free. Since $6e_3 = 0$, each element of $\{e_1 \wedge e_3, e_2 \wedge e_3, e_1 \wedge e_2 \wedge e_3\}$ is annihilated by $6\mathbb{Z} = (6)$. Since $2e_4 = 0$, each element of $\{e_1 \wedge e_4, e_2 \wedge e_4, e_3 \wedge e_4, e_1 \wedge e_2 \wedge e_4, e_1 \wedge e_3 \wedge e_4, e_2 \wedge e_3 \wedge e_4, e_1 \wedge e_2 \wedge e_3 \wedge e_4\}$ is annihilated by $2\mathbb{Z} = (2)$.

Then

$$\begin{aligned}\text{Ann}(\bigwedge^1 M) &= \text{Ann } e_1 = (0) \\ \text{Ann}(\bigwedge^2 M) &= \text{Ann } e_1 \wedge e_2 = (0) \\ \text{Ann}(\bigwedge^3 M) &= \text{Ann } e_1 \wedge e_2 \wedge e_3 = (6) \\ \text{Ann}(\bigwedge^4 M) &= \text{Ann } e_1 \wedge e_2 \wedge e_3 \wedge e_4 = (2),\end{aligned}$$

and Proposition 35.29 provides another verification of

$$M \cong \mathbb{Z} \oplus \mathbb{Z} \oplus \mathbb{Z}/(6) \oplus \mathbb{Z}/(2).$$

Proposition 35.29 immediately implies the following crucial fact.

Proposition 35.30. *Let A be a commutative ring and let $\mathfrak{a}_1, \dots, \mathfrak{a}_m$ be m ideals of A and $\mathfrak{a}'_1, \dots, \mathfrak{a}'_n$ be n ideals of A such that $\mathfrak{a}_1 \subseteq \mathfrak{a}_2 \subseteq \dots \subseteq \mathfrak{a}_m \neq A$ and $\mathfrak{a}'_1 \subseteq \mathfrak{a}'_2 \subseteq \dots \subseteq \mathfrak{a}'_n \neq A$. If we have an isomorphism*

$$A/\mathfrak{a}_1 \oplus \dots \oplus A/\mathfrak{a}_m \approx A/\mathfrak{a}'_1 \oplus \dots \oplus A/\mathfrak{a}'_n,$$

then $m = n$ and $\mathfrak{a}_i = \mathfrak{a}'_i$ for $i = 1, \dots, n$.

Proposition 35.30 yields the uniqueness of the decomposition in Theorem 35.25.

Theorem 35.31. (Invariant Factors Decomposition) *Let M be a finitely generated nontrivial A -module, where A a PID. Then, M is isomorphic to a direct sum of cyclic modules*

$$M \approx A/\mathfrak{a}_1 \oplus \dots \oplus A/\mathfrak{a}_m,$$

where the \mathfrak{a}_i are proper ideals of A (possibly zero) such that

$$\mathfrak{a}_1 \subseteq \mathfrak{a}_2 \subseteq \dots \subseteq \mathfrak{a}_m \neq A.$$

More precisely, if $\mathfrak{a}_1 = \dots = \mathfrak{a}_r = (0)$ and $(0) \neq \mathfrak{a}_{r+1} \subseteq \dots \subseteq \mathfrak{a}_m \neq A$, then

$$M \approx A^r \oplus (A/\mathfrak{a}_{r+1} \oplus \dots \oplus A/\mathfrak{a}_m),$$

where $A/\mathfrak{a}_{r+1} \oplus \dots \oplus A/\mathfrak{a}_m$ is the torsion submodule of M . The module M is free iff $r = m$, and a torsion-module iff $r = 0$. In the latter case, the annihilator of M is \mathfrak{a}_1 . Furthermore, the integer r and ideals $\mathfrak{a}_1 \subseteq \mathfrak{a}_2 \subseteq \dots \subseteq \mathfrak{a}_m \neq A$ are uniquely determined by M .

Proof. By Theorem 35.7, since $M_{\text{tor}} = A/\mathfrak{a}_{r+1} \oplus \dots \oplus A/\mathfrak{a}_m$, we know that the dimension r of the free summand only depends on M . The uniqueness of the sequence of ideals follows from Proposition 35.30. \square

In view of the uniqueness part of Theorem 35.31, we make the following definition.

Definition 35.12. Given a finitely generated module M over a PID A as in Theorem 35.31, the ideals $\mathfrak{a}_i = \alpha_i A$ are called the *invariant factors* of M . The generators α_i of these ideals (uniquely defined up to a unit) are also called the *invariant factors* of M .

Proposition 35.23 can be sharpened as follows:

Proposition 35.32. *Let F be a finitely generated free module over a PID A , and let M be any submodule of F . Then, M is a free module and there is a basis (e_1, \dots, e_n) of F , some $q \leq n$, and some nonzero elements $a_1, \dots, a_q \in A$, such that $(a_1 e_1, \dots, a_q e_q)$ is a basis of M and a_i divides a_{i+1} for all i , with $1 \leq i \leq q-1$. Furthermore, the free module M' with basis (e_1, \dots, e_q) and the ideals $a_1 A, \dots, a_q A$ are uniquely determined by M ; the quotient module M'/M is the torsion module of F/M , and we have an isomorphism*

$$M'/M \approx A/a_1 A \oplus \cdots \oplus A/a_q A.$$

Proof. Since $a_i \neq 0$ for $i = 1, \dots, q$, observe that

$$M' = \{x \in F \mid (\exists \beta \in A, \beta \neq 0)(\beta x \in M)\},$$

which shows that M'/M is the torsion module of F/M . Therefore, M' is uniquely determined. Since

$$M = Aa_1 e_1 \oplus \cdots \oplus Aa_q e_q,$$

by Proposition 35.24 we have an isomorphism

$$M'/M \approx A/a_1 A \oplus \cdots \oplus A/a_q A.$$

Now, it is possible that the first s elements a_i are units, in which case $A/a_i A = (0)$, so we can eliminate such factors and we get

$$M'/M \approx A/a_{s+1} A \oplus \cdots \oplus A/a_q A,$$

with $a_q A \subseteq a_{q-1} A \subseteq \cdots \subseteq a_{s+1} A \neq A$. By Proposition 35.30, $q-s$ and the ideals $a_j A$ are uniquely determined for $j = s+1, \dots, q$, and since $a_1 A = \cdots = a_s A = A$, the q ideals $a_i A$ are uniquely determined. \square

The ideals $a_1 A, \dots, a_q A$ of Proposition 35.32 are called the *invariant factors of M with respect to F* . They *should not be confused* with the invariant factors of a module M .

It turns out that a_1, \dots, a_q can also be computed in terms of gcd's of minors of a certain matrix. Recall that if X is an $m \times n$ matrix, then a $k \times k$ minor of X is the determinant of any $k \times k$ matrix obtained by picking k columns of X , and then k rows from these k columns.

Proposition 35.33. *Let F be a free module of finite dimension over a PID, (u_1, \dots, u_n) be a basis of F , M be a submodule of F , and (x_1, \dots, x_m) be a set of generators of M . If a_1A, \dots, a_qA are the invariant factors of M with respect to F as in Proposition 35.32, then for $k = 1, \dots, q$, the product $a_1 \cdots a_k$ is a gcd of the $k \times k$ minors of the $n \times m$ matrix X_U whose columns are the coordinates of the x_j over the u_i .*

Proof. Proposition 35.23 shows that $M \subseteq a_1F$. Consequently, the coordinates of any element of M are multiples of a_1 . On the other hand, we know that there is a linear form f for which a_1A is a maximal ideal and some $e' \in M$ such that $f(e') = a_1$. If we write e' as a linear combination of the x_i , we see that a_1 belongs to the ideal spanned by the coordinates of the x_i over the basis (u_1, \dots, u_n) . Since these coordinates are all multiples of a_1 , it follows that a_1 is their gcd, which proves the case $k = 1$.

For any $k \geq 2$, consider the exterior power $\bigwedge^k M$. Using the notation of the proof of Proposition 35.23, the module M has the basis (a_1e_1, \dots, a_qe_q) , so $\bigwedge^k M$ has a basis consisting of elements of the form

$$a_{i_1}e_{i_1} \wedge \cdots \wedge a_{i_k}e_{i_k} = a_{i_1} \cdots a_{i_k} e_{i_1} \wedge \cdots \wedge e_{i_k},$$

for all sequences (i_1, \dots, i_k) such that $1 \leq i_1 < i_2 < \cdots < i_k \leq q$. However, the vectors $e_{i_1} \wedge \cdots \wedge e_{i_k}$ form a basis of $\bigwedge^k F$. Thus, the map from $\bigwedge^k M$ into $\bigwedge^k F$ induced by the inclusion $M \subseteq F$ defines an isomorphism of $\bigwedge^k M$ onto the submodule of $\bigwedge^k F$ having the elements $a_{i_1} \cdots a_{i_k} e_{i_1} \wedge \cdots \wedge e_{i_k}$ as a basis. Since a_j is a multiple of the a_i for $i < j$, the products $a_{i_1} \cdots a_{i_k}$ are all multiples of $\delta_k = a_1 \cdots a_k$, and one of these is equal to δ_k . The reasoning used for $k = 1$ shows that δ_k is a gcd of the set of coordinates of any spanning set of $\bigwedge^k M$ over any basis of $\bigwedge^k F$. If we pick as basis of $\bigwedge^k F$ the wedge products $u_{i_1} \wedge \cdots \wedge u_{i_k}$, and as generators of $\bigwedge^k M$ the wedge products $x_{i_1} \wedge \cdots \wedge x_{i_k}$, it is easy to see that the coordinates of the $x_{i_1} \wedge \cdots \wedge x_{i_k}$ are indeed determinants which are the $k \times k$ minors of the matrix X_U . \square

Proposition 35.33 yields a_1, \dots, a_q (up to units) as follows: First, a_1 is a gcd of the entries in X_U . Having computed a_1, \dots, a_k , let $b_k = a_1 \cdots a_k$, compute $b_{k+1} = a_1 \cdots a_k a_{k+1}$ as a gcd of all the $(k+1) \times (k+1)$ minors of X_U , and then a_{k+1} is obtained by dividing b_{k+1} by b_k (recall that a PID is an integral domain).

We also have the following interesting result about linear maps between free modules over a PID.

Proposition 35.34. *Let A be a PID, let F be a free module of dimension n , F' be a free module of dimension m , and $f: F \rightarrow F'$ be a linear map from F to F' . Then, there exist a basis (e_1, \dots, e_n) of F , a basis (e'_1, \dots, e'_m) of F' , and some nonzero elements $\alpha_1, \dots, \alpha_r \in A$ such that*

$$f(e_i) = \begin{cases} \alpha_i e'_i & \text{if } 1 \leq i \leq r \\ 0 & \text{if } r+1 \leq i \leq n, \end{cases}$$

and $\alpha_1 \mid \alpha_2 \mid \cdots \mid \alpha_r$. Furthermore, the ideals $\alpha_1A, \dots, \alpha_rA$ are the invariant factors of $f(F)$ with respect to F' .

Proof. Let F_0 be the kernel of f . Since $M' = f(F)$ is a submodule of the free module F' , it is free, and similarly F_0 is free as a submodule of the free module F (by Proposition 35.23). By Proposition 35.2, we have

$$F = F_0 \oplus F_1,$$

where F_1 is a free module, and the restriction of f to F_1 is an isomorphism onto $M' = f(F)$. Proposition 35.32 applied to F' and M' yields a basis (e'_1, \dots, e'_m) of F' such that $(\alpha_1e'_1, \dots, \alpha_re'_r)$ is a basis of M' , where $\alpha_1A, \dots, \alpha_rA$ are the invariant factors for M' with respect to F' . Since the restriction of f to F_1 is an isomorphism, there is a basis (e_1, \dots, e_r) of F_1 such that

$$f(e_i) = \alpha_i e'_i, \quad i = 1, \dots, r.$$

We can extend this basis to a basis of F by picking a basis of F_0 (a free module), which yields the desired result. \square

The matrix version of Proposition 35.34 is the following proposition.

Proposition 35.35. *If X is an $m \times n$ matrix of rank r over a PID A , then there exist some invertible $n \times n$ matrix P , some invertible $m \times m$ matrix Q , and a $m \times n$ matrix D of the form*

$$D = \begin{pmatrix} \alpha_1 & 0 & \cdots & 0 & 0 & \cdots & 0 \\ 0 & \alpha_2 & \cdots & 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots & \cdots & \vdots \\ 0 & 0 & \cdots & \alpha_r & 0 & \cdots & 0 \\ 0 & 0 & \cdots & 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \cdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 & 0 & \cdots & 0 \end{pmatrix}$$

for some nonzero $\alpha_i \in A$, such that

- (1) $\alpha_1 \mid \alpha_2 \mid \cdots \mid \alpha_r$,
- (2) $X = QDP^{-1}$, and
- (3) The α_i s are uniquely determined up to a unit.

The ideals $\alpha_1A, \dots, \alpha_rA$ are called the *invariant factors* of the matrix X . Recall that two $m \times n$ matrices X and Y are *equivalent* iff

$$Y = QXP^{-1},$$

for some invertible matrices, P and Q . Then, Proposition 35.35 implies the following fact.

Proposition 35.36. *Two $m \times n$ matrices X and Y are equivalent iff they have the same invariant factors.*

If X is the matrix of a linear map $f: F \rightarrow F'$ with respect to some basis (u_1, \dots, u_n) of F and some basis (u'_1, \dots, u'_m) of F' , then the columns of X are the coordinates of the $f(u_j)$ over the u'_i , where the $f(u_j)$ generate $f(F)$, so Proposition 35.33 applies and yields the following result:

Proposition 35.37. *If X is a $m \times n$ matrix or rank r over a PID A , and if $\alpha_1 A, \dots, \alpha_r A$ are its invariant factors, then α_1 is a gcd of the entries in X , and for $k = 2, \dots, r$, the product $\alpha_1 \cdots \alpha_k$ is a gcd of all $k \times k$ minors of X .*

There are algorithms for converting a matrix X over a PID to the form $X = QDP^{-1}$ as described in Proposition 35.35. For Euclidean domains, this can be achieved by using the elementary row and column operations $P(i, k)$, $E_{i,j;\beta}$, and $E_{i,\lambda}$ described in Chapter 8, where we require the scalar λ used in $E_{i,\lambda}$ to be a unit. For an arbitrary PID, another kind of elementary matrix (containing some 2×2 submatrix in addition to diagonal entries) is needed. These procedures involve computing gcd's and use the Bezout identity to mimic division. Such methods are presented in D. Serre [156], Jacobson [98], and Van Der Waerden [179], and sketched in Artin [7]. We describe and justify several of these methods in Section 36.5.

Proposition 35.32 has the following two applications.

First, consider a finitely presented module M over a PID given by some $m \times n$ matrix R . By Proposition 35.35, the matrix R can be diagonalized as $R = QDP^{-1}$ where D is a diagonal matrix. Then, we see that M has a presentation with m generators and r relations of the form

$$\alpha_i e_i = 0,$$

where $\alpha_i \neq 0$ and $\alpha_1 | \alpha_2 | \cdots | \alpha_r$.

For the second application, let F be a free module with basis (e_1, \dots, e_n) , and let M be a submodule of F generated by m vectors v_1, \dots, v_m in F . The module M can be viewed as the set of linear combinations of the columns of the $n \times m$ matrix also denoted M consisting of the coordinates of the vectors v_1, \dots, v_m over the basis (e_1, \dots, e_n) . Then by Proposition 35.35, the matrix R can be diagonalized as $R = QDP^{-1}$ where D is a diagonal matrix. The columns of Q form a basis (e'_1, \dots, e'_n) of F , and since $RP = QD$, the nonzero columns of RP form the basis $(a_1 e'_1, \dots, a_q e'_q)$ of M .

When the ring A is a Euclidean domain, Theorem 36.18 shows that P and Q are products of elementary row and column operations. In particular, when $A = \mathbb{Z}$, in which cases our \mathbb{Z} -modules are abelian groups, we can find P and Q using Euclidean division.

If $A = \mathbb{Z}$, a finitely generated submodule M of \mathbb{Z}^n is called a *lattice*. It is given as the set of integral linear combinations of a finite set of integral vectors.

Here is an example taken from Artin [7] (Chapter 12, Section 4). Let F be the free \mathbb{Z} -module \mathbb{Z}^2 , and let M be the lattice generated by the columns of the matrix

$$R = \begin{pmatrix} 2 & -1 \\ 1 & 2 \end{pmatrix}.$$

The columns (u_1, u_2) of R are linearly independent, but they are not a basis of \mathbb{Z}^2 . For example, in order to obtain e_1 as a linear combination of these columns, we would need to solve the linear system

$$\begin{aligned} 2x - y &= 1 \\ x + 2y &= 0. \end{aligned}$$

From the second equation, we get $x = -2y$, which yields

$$-5y = 1.$$

But, $y = -1/5$ is not an integer. We leave it as an exercise to check that

$$\begin{pmatrix} 1 & 0 \\ -3 & 1 \end{pmatrix} \begin{pmatrix} 2 & -1 \\ 1 & 2 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 5 \end{pmatrix},$$

which means that

$$\begin{pmatrix} 2 & -1 \\ 1 & 2 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 3 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 5 \end{pmatrix} \begin{pmatrix} 2 & -1 \\ -1 & 1 \end{pmatrix},$$

so $R = QDP^{-1}$ with

$$Q = \begin{pmatrix} 1 & 0 \\ 3 & 1 \end{pmatrix}, \quad D = \begin{pmatrix} 1 & 0 \\ 0 & 5 \end{pmatrix}, \quad P = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix}.$$

The new basis (u'_1, u'_2) for \mathbb{Z}^2 consists of the columns of Q and the new basis for M consists of the columns $(u'_1, 5u'_2)$ of QD , where

$$QD = \begin{pmatrix} 1 & 0 \\ 3 & 5 \end{pmatrix}.$$

A picture of the lattice and its generators (u_1, u_2) and of the same lattice with the new basis $(u'_1, 5u'_2)$ is shown in Figure 35.1, where the lattice points are displayed as stars.

The invariant factor decomposition of a finitely generated module M over a PID A given by Theorem 35.31 says that

$$M_{\text{tor}} \approx A/\mathfrak{a}_{r+1} \oplus \cdots \oplus A/\mathfrak{a}_m,$$

a direct sum of cyclic modules, with $(0) \neq \mathfrak{a}_{r+1} \subseteq \cdots \subseteq \mathfrak{a}_m \neq A$. Using the Chinese Remainder Theorem (Theorem 32.15), we can further decompose each module $A/\mathfrak{a}_i A$ into a direct sum of modules of the form $A/p^n A$, where p is a prime in A .

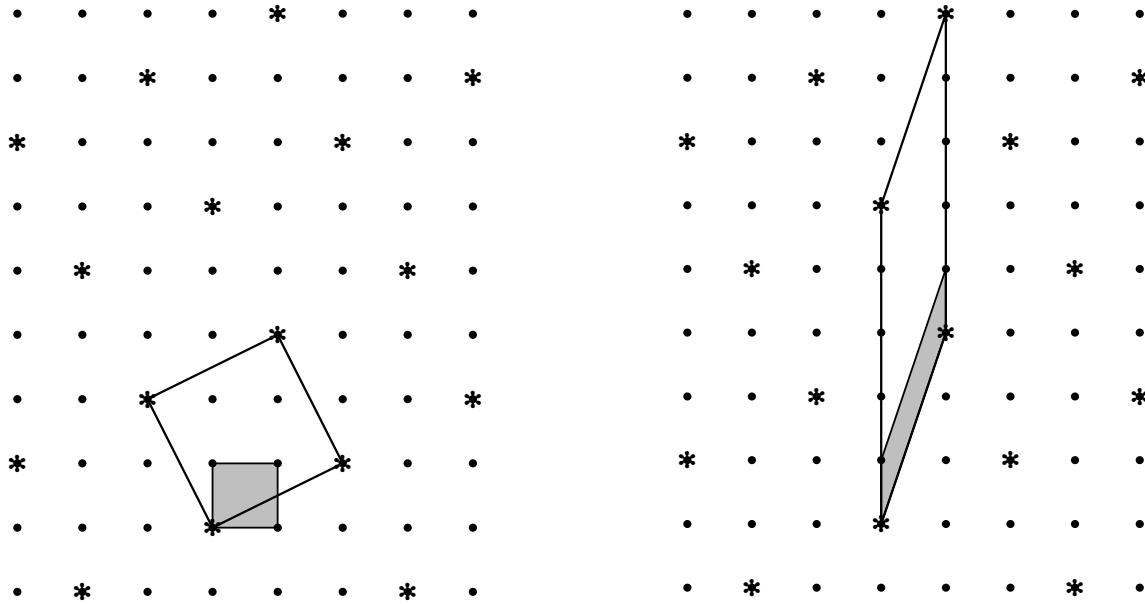

Figure 35.1: Diagonalization applied to a lattice

Theorem 35.38. (Elementary Divisors Decomposition) Let M be a finitely generated non-trivial A -module, where A a PID. Then, M is isomorphic to the direct sum $A^r \oplus M_{\text{tor}}$, where A^r is a free module and where the torsion module M_{tor} is a direct sum of cyclic modules of the form $A/p_i^{n_{i,j}}$, for some primes $p_1, \dots, p_t \in A$ and some positive integers $n_{i,j}$, such that for each $i = 1, \dots, t$, there is a sequence of integers

$$1 \leq \underbrace{n_{i,1}, \dots, n_{i,1}}_{m_{i,1}} < \underbrace{n_{i,2}, \dots, n_{i,2}}_{m_{i,2}} < \cdots < \underbrace{n_{i,s_i}, \dots, n_{i,s_i}}_{m_{i,s_i}},$$

with $s_i \geq 1$, and where $n_{i,j}$ occurs $m_{i,j} \geq 1$ times, for $j = 1, \dots, s_i$. Furthermore, the irreducible elements p_i and the integers $r, t, n_{i,j}, s_i, m_{i,j}$ are uniquely determined.

Proof. By Theorem 35.31, we already know that $M \approx A^r \oplus M_{\text{tor}}$, where r is uniquely determined, and where

$$M_{\text{tor}} \approx A/\mathfrak{a}_{r+1} \oplus \cdots \oplus A/\mathfrak{a}_m,$$

a direct sum of cyclic modules, with $(0) \neq \mathfrak{a}_{r+1} \subseteq \cdots \subseteq \mathfrak{a}_m \neq A$. Then, each \mathfrak{a}_i is a principal ideal of the form $\alpha_i A$, where $\alpha_i \neq 0$ and α_i is not a unit. Using the Chinese Remainder Theorem (Theorem 32.15), if we factor α_i into prime factors as

$$\alpha_i = up_1^{k_1} \cdots p_h^{k_h},$$

with $k_j \geq 1$, we get an isomorphism

$$A/\alpha_i A \approx A/p_1^{k_1} A \oplus \cdots \oplus A/p_h^{k_h} A.$$

This implies that M_{tor} is the direct sum of modules of the form $A/p_i^{n_{i,j}}$, for some primes $p_i \in A$.

To prove uniqueness, observe that the p_i -primary component of M_{tor} is the direct sum

$$(A/p_i^{n_{i,1}} A)^{m_{i,1}} \oplus \cdots \oplus (A/p_i^{n_{i,s_i}} A)^{m_{i,s_i}},$$

and these are uniquely determined. Since $n_{i,1} < \cdots < n_{i,s_i}$, we have

$$p_i^{n_{i,s_i}} A \subseteq \cdots \subseteq p_i^{n_{i,1}} A \neq A,$$

Proposition 35.30 implies that the irreducible elements p_i and $n_{i,j}$, s_i , and $m_{i,j}$ are unique. \square

In view of Theorem 35.38, we make the following definition.

Definition 35.13. Given a finitely generated module M over a PID A as in Theorem 35.38, the ideals $p_i^{n_{i,j}} A$ are called the *elementary divisors* of M , and the $m_{i,j}$ are their *multiplicities*. The ideal (0) is also considered to be an elementary divisor and r is its multiplicity.

Remark: Theorem 35.38 shows how the elementary divisors are obtained from the invariant factors: the elementary divisors are the prime power factors of the invariant factors.

Conversely, we can get the invariant factors from the elementary divisors. We may assume that M is a torsion module. Let

$$m = \max_{1 \leq i \leq t} \{m_{i,1} + \cdots + m_{i,s_i}\},$$

and construct the $t \times m$ matrix $C = (c_{ij})$ whose i th row is the sequence

$$\underbrace{n_{i,s_i}, \dots, n_{i,s_i}}_{m_{i,s_i}}, \dots, \underbrace{n_{i,2}, \dots, n_{i,2}}_{m_{i,2}}, \underbrace{n_{i,1}, \dots, n_{i,1}}_{m_{i,1}}, 0, \dots, 0,$$

padded with 0's if necessary to make it of length m . Then, the j th invariant factor is

$$\alpha_j A = p_1^{c_{1j}} p_2^{c_{2j}} \cdots p_t^{c_{tj}} A.$$

Observe that because the last column contains at least one prime, the α_i are not units, and $\alpha_m \mid \alpha_{m-1} \mid \cdots \mid \alpha_1$, so that $\alpha_1 A \subseteq \cdots \subseteq \alpha_{m-1} A \subseteq \alpha_m A \neq A$, as desired.

From a computational point of view, finding the elementary divisors is usually practically impossible, because it requires factoring. For example, if $A = K[X]$ where K is a field, such as $K = \mathbb{R}$ or $K = \mathbb{C}$, factoring amounts to finding the roots of a polynomial, but by Galois theory, in general, this is not algorithmically doable. On the other hand, the invariant factors can be computed using elementary row and column operations.

It can also be shown that A and the modules of the form $A/p^n A$ are indecomposable (with $n > 0$). A module M is said to be *indecomposable* if M cannot be written as a direct

sum of two nonzero proper submodules of M . For a proof, see Bourbaki [26] (Chapter VII, Section 4, No. 8, Proposition 8). Theorem 35.38 shows that a finitely generated module over a PID is a direct sum of indecomposable modules.

In Chapter 36 we apply the structure theorems for finitely generated (torsion) modules to the $K[X]$ -module E_f associated with an endomorphism f on a vector space E . First, we need to understand the process of extension of the ring of scalars.

35.6 Extension of the Ring of Scalars

The need to extend the ring of scalars arises, in particular when dealing with eigenvalues. First we need to define how to restrict scalar multiplication to a subring. The situation is that we have two rings A and B , a B -module M , and a ring homomorphism $\rho: A \rightarrow B$. The special case that arises often is that A is a subring of B (B could be a field) and ρ is the inclusion map. Then we can make M into an A -module by defining the scalar multiplication $\cdot: A \times M \rightarrow M$ as follows.

Definition 35.14. Given two rings A and B and a ring homomorphism $\rho: A \rightarrow B$, any B -module M can made into an A -module denoted by $\rho_*(M)$, by defining scalar multiplication by any element of A as follows:

$$a \cdot x = \rho(a)x, \quad \text{for all } a \in A \text{ and all } x \in M.$$

In particular, viewing B as a B -module, we obtain the A -module $\rho_*(B)$.

If M and N are two B -modules and if $f: M \rightarrow N$ is a B -linear map, the map f is a homomorphism $f: \rho_*(M) \rightarrow \rho_*(N)$ of the abelian groups $\rho_*(M)$ and $\rho_*(N)$. This map is also A -linear, because for all $u \in M$ and all $a \in A$, by definition of the scalar multiplication by elements of A , we have

$$f(a \cdot u) = f(\rho(a)u) = \rho(a)f(u) = a \cdot f(u).$$

The map $f: \rho_*(M) \rightarrow \rho_*(N)$ viewed as an A -linear map is denoted by $\rho_*(f)$. As homomorphisms of abelian groups, the maps $f: M \rightarrow N$ and $\rho_*(f): \rho_*(M) \rightarrow \rho_*(N)$ are identical, but f is a B -linear map whereas $\rho_*(f)$ is an A -linear map.

Now we can describe the process of scalar extension. Given any A -module M , we make $\rho_*(B) \otimes_A M$ into a (left) B -module as follows: for every $\beta \in B$, let $\mu_\beta: \rho_*(B) \times M \rightarrow \rho_*(B) \otimes_A M$ be given by

$$\mu_\beta(\beta', x) = (\beta\beta') \otimes x.$$

The map μ_β is bilinear so it induces a linear map $\mu_\beta: \rho_*(B) \otimes_A M \rightarrow \rho_*(B) \otimes_A M$ such that

$$\mu_\beta(\beta' \otimes x) = (\beta\beta') \otimes x.$$

If we define the scalar multiplication $\cdot: B \times (\rho_*(B) \otimes_A M) \rightarrow \rho_*(B) \otimes_A M$ by

$$\beta \cdot z = \mu_\beta(z), \quad \text{for all } \beta \in B \text{ and all } z \in \rho_*(B) \otimes_A M,$$

then it is easy to check that the axioms M1, M2, M3, M4 hold. Let us check M2 and M3. We have

$$\begin{aligned} \mu_{\beta_1+\beta_2}(\beta' \otimes x) &= (\beta_1 + \beta_2)\beta' \otimes x \\ &= (\beta_1\beta' + \beta_2\beta') \otimes x \\ &= \beta_1\beta' \otimes x + \beta_2\beta' \otimes x \\ &= \mu_{\beta_1}(\beta' \otimes x) + \mu_{\beta_2}(\beta' \otimes x) \end{aligned}$$

and

$$\begin{aligned} \mu_{\beta_1\beta_2}(\beta' \otimes x) &= \beta_1\beta_2\beta' \otimes x \\ &= \mu_{\beta_1}(\beta_2\beta' \otimes x) \\ &= \mu_{\beta_1}(\mu_{\beta_2}(\beta' \otimes x)). \end{aligned}$$

Definition 35.15. Given two rings A and B and a ring homomorphism $\rho: A \rightarrow B$, for any A -module M , with the scalar multiplication by elements of B given by

$$\beta \cdot (\beta' \otimes x) = (\beta\beta') \otimes x, \quad \beta, \beta' \in B, x \in M,$$

the tensor product $\rho_*(B) \otimes_A M$ is a B -module denoted by $\rho^*(M)$, or $M_{(B)}$ when ρ is the inclusion of A into B . The B -module $\rho^*(M)$ is sometimes called the *module induced from M by extension to B of the ring of scalars through ρ* .

Here is a specific example of Definition 35.15. Let $A = \mathbb{R}$, $B = \mathbb{C}$ and ρ be the inclusion map of \mathbb{R} into \mathbb{C} , i.e. $\rho: \mathbb{R} \rightarrow \mathbb{C}$ with $\rho(a) = a$ for $a \in \mathbb{R}$. Let M be an \mathbb{R} -module. The field \mathbb{C} is a \mathbb{C} -module, and when we restrict scalar multiplication by scalars $\lambda \in \mathbb{R}$, we obtain the \mathbb{R} -module $\rho_*(\mathbb{C})$ (which, as an abelian group, is just \mathbb{C}). Form $\rho_*(\mathbb{C}) \otimes_{\mathbb{R}} M$. This is an \mathbb{R} -module where typical elements have the form $\sum_{i=1}^n a_i(z_i \otimes m_i)$, $a_i \in \mathbb{R}$, $z_i \in \mathbb{C}$, and $m_i \in M$. Since

$$a_i(z_i \otimes m_i) = a_i z_i \otimes m_i$$

and since $a_i z_i \in \mathbb{C}$ and any element of \mathbb{C} is obtained this way (let $a_i = 1$), the elements of $\rho_*(\mathbb{C}) \otimes_{\mathbb{R}} M$ can be written as

$$\sum_{i=1}^n z_i \otimes m_i, \quad z_i \in \mathbb{C}, m_i \in M.$$

We want to make $\rho_*(\mathbb{C}) \otimes_{\mathbb{R}} M$ into a \mathbb{C} -module, denoted $\rho^*(M)$, and thus must describe how a complex number β acts on $\sum_{i=1}^n z_i \otimes m_i$. By linearity, it is enough to determine how $\beta = u + iv$ acts on a generator $z \otimes m$, where $z = x + iy$ and $m \in M$. The action is given by

$$\beta \cdot (z \otimes m) = \beta z \otimes m = (u + iv)(x + iy) \otimes m = (ux - vy + i(uy + vx)) \otimes m,$$

since complex multiplication only makes sense over \mathbb{C} .

We claim that $\rho^*(M)$ is isomorphic to the \mathbb{C} -module $M \times M$ with addition defined by

$$(u_1, v_1) + (u_2, v_2) = (u_1 + u_2, v_1 + v_2)$$

and scalar multiplication by $\lambda + i\mu \in \mathbb{C}$ as

$$(\lambda + i\mu) \cdot (u, v) = (\lambda u - \mu v, \lambda v + \mu u).$$

Define the map $\alpha_0: \rho_*(\mathbb{C}) \times M \rightarrow M \times M$ by

$$\alpha_0(\lambda + i\mu, u) = (\lambda u, \mu u).$$

It is easy to check that α_0 is \mathbb{R} -linear, so we obtain an \mathbb{R} -linear map $\alpha: \rho_*(\mathbb{C}) \otimes_{\mathbb{R}} M \rightarrow M \times M$ such that

$$\alpha((\lambda + i\mu) \otimes u) = (\lambda u, \mu u).$$

We also define the map $\beta: M \times M \rightarrow \rho_*(\mathbb{C}) \otimes_{\mathbb{R}} M$ by

$$\beta(u, v) = 1 \otimes u + i \otimes v.$$

Again, it is clear that this map is \mathbb{R} -linear. We can now check that α and β are mutual inverses. We have

$$\alpha(\beta(u, v)) = \alpha(1 \otimes u + i \otimes v) = \alpha(1 \otimes u) + \alpha(i \otimes v) = (u, 0) + (0, v) = (u, v),$$

and on generators,

$$\beta(\alpha((\lambda + i\mu) \otimes u)) = \beta(\lambda u, \mu u) = 1 \otimes \lambda u + i \otimes \mu u = \lambda \otimes u + i \otimes \mu u = (\lambda + i\mu) \otimes u.$$

Therefore, $\rho_*(\mathbb{C}) \otimes_{\mathbb{R}} M$ and $M \times M$ are isomorphic as \mathbb{R} -module. However, the isomorphism α is also an isomorphism of \mathbb{C} -modules. This is because in $\rho_*(\mathbb{C}) \otimes_{\mathbb{R}} M$, on generators we have

$$(\lambda + i\mu) \cdot ((x + iy) \otimes u) = (\lambda + i\mu)(x + iy) \otimes u = (\lambda x - \mu y + i(\lambda y + \mu x)) \otimes u,$$

so

$$\begin{aligned} \alpha((\lambda + i\mu) \cdot ((x + iy) \otimes u)) &= \alpha((\lambda x - \mu y + i(\lambda y + \mu x)) \otimes u) \\ &= ((\lambda x - \mu y)u, (\lambda y + \mu x)u), \end{aligned}$$

and by definition of the scalar multiplication by elements of \mathbb{C} on $M \times M$

$$(\lambda + i\mu) \cdot \alpha((x + iy) \otimes u) = (\lambda + i\mu) \cdot (xu, yu) = ((\lambda x - \mu y)u, (\lambda y + \mu x)u).$$

Therefore, α is isomorphism between the \mathbb{C} -modules $\rho^*(M) = \rho_*(\mathbb{C}) \otimes_{\mathbb{R}} M$ and $M \times M$.

The above process of ring extension can also be applied to linear maps. We have the following proposition whose proof is given in Bourbaki [25] (Chapter II, Section 5, Proposition 1).

Proposition 35.39. *Given a ring homomorphism $\rho: A \rightarrow B$ and given any A -module M , the map $\varphi: M \rightarrow \rho_*(\rho^*(M))$ given by $\varphi(x) = 1 \otimes_A x$ is A -linear and $\varphi(M)$ spans the B -module $\rho^*(M)$. For every B -module N , and for every A -linear map $f: M \rightarrow \rho_*(N)$, there is a unique B -linear map*

$$\bar{f}: \rho^*(M) \rightarrow N$$

such that

$$\rho_*(\bar{f}) \circ \varphi = f$$

as in the following commutative diagram

$$\begin{array}{ccc} M & \xrightarrow{\varphi} & \rho_*(\rho^*(M)) \\ & \searrow f & \downarrow \rho_*(\bar{f}) \\ & & \rho_*(N) \end{array}$$

or equivalently,

$$\bar{f}(1 \otimes_A x) = f(x), \quad \text{for all } x \in M.$$

As a consequence of Proposition 35.39, we obtain the following result.

Proposition 35.40. *Given a ring homomorphism $\rho: A \rightarrow B$, for any two A -modules M and N , for every A -linear map $f: M \rightarrow N$, there is a unique B -linear map $\rho^*(f): \rho^*(M) \rightarrow \rho^*(N)$ (also denoted \bar{f}) given by*

$$\rho^*(f) = \text{id}_B \otimes f,$$

such that the following diagram commutes:

$$\begin{array}{ccc} M & \xrightarrow{\varphi_M} & \rho_*(\rho^*(M)) \\ \downarrow f & & \downarrow \rho_*(\rho^*(f)) \\ N & \xrightarrow{\varphi_N} & \rho_*(\rho^*(N)) \end{array}$$

Proof. Apply Proposition 35.40 to the A -linear map $\varphi_N \circ f$. □

If S spans the module M , it is clear that $\varphi(S)$ spans $\rho^*(M)$. In particular, if M is finitely generated, so is $\rho^*(M)$. Bases of M also extend to bases of $\rho^*(M)$.

Proposition 35.41. *Given a ring homomorphism $\rho: A \rightarrow B$, for any A -module M , if (u_1, \dots, u_n) is a basis of M , then $(\varphi(u_1), \dots, \varphi(u_n))$ is a basis of $\rho^*(M)$, where φ is the A -linear map $\varphi: M \rightarrow \rho_*(\rho^*(M))$ given by $\varphi(x) = 1 \otimes_A x$. Furthermore, if ρ is injective, then so is φ .*

Proof. The first assertion follows immediately from Proposition 35.13, since it asserts that every element z of $\rho^*(M) = \rho_*(B) \otimes_A M$ can be written in a unique way as

$$z = b_1 \otimes u_1 + \cdots + b_n \otimes u_n = b_1(1 \otimes u_1) + \cdots + b_n(1 \otimes u_n),$$

and $\varphi(u_i) = 1 \otimes u_i$. Next, if ρ is injective, by definition of the scalar multiplication in the A -module $\rho_*(\rho^*(M))$, we have $\varphi(a_1u_1 + \cdots + a_nu_n) = 0$ iff

$$\rho(a_1)\varphi(u_1) + \cdots + \rho(a_n)\varphi(u_n) = 0,$$

and since $(\varphi(u_1), \dots, \varphi(u_n))$ is a basis of $\rho^*(M)$, we must have $\rho(a_i) = 0$ for $i = 1, \dots, n$, which (by injectivity of ρ) implies that $a_i = 0$ for $i = 1, \dots, n$. Therefore, φ is injective. \square

In particular, if A is a subring of B , then ρ is the inclusion map and Proposition 35.41 shows that a basis of M becomes a basis of $M_{(B)}$ and that M is embedded into $M_{(B)}$. It is also easy to see that if M and N are two free A -modules and $f: M \rightarrow N$ is a linear map represented by the matrix X with respect to some bases (u_1, \dots, u_n) of M and (v_1, \dots, v_m) of N , then the B -linear map \bar{f} is also represented by the matrix X over the bases $(\varphi(u_1), \dots, \varphi(u_n))$ and $(\varphi(v_1), \dots, \varphi(v_m))$.

Proposition 35.41 yields another proof of the fact that any two bases of a free A -modules have the same cardinality. Indeed, if \mathfrak{m} is a maximal ideal in the ring A , then we have the quotient ring homomorphism $\pi: A \rightarrow A/\mathfrak{m}$, and we get the A/\mathfrak{m} -module $\pi^*(M)$. If M is free, any basis (u_1, \dots, u_n) of M becomes the basis $(\varphi(u_1), \dots, \varphi(u_n))$ of $\pi^*(M)$; but A/\mathfrak{m} is a field, so the dimension n is uniquely determined. This argument also applies to an infinite basis $(u_i)_{i \in I}$. Observe that by Proposition 35.14, we have an isomorphism

$$\pi^*(M) = (A/\mathfrak{m}) \otimes_A M \approx M/\mathfrak{m}M,$$

so $M/\mathfrak{m}M$ is a vector space over the field A/\mathfrak{m} , which is the argument used in Theorem 35.1.

Proposition 35.42. *Given a ring homomorphism $\rho: A \rightarrow B$, for any two A -modules M and N , there is a unique isomorphism*

$$\rho^*(M) \otimes_B \rho^*(N) \approx \rho^*(M \otimes_A N),$$

such that $(1 \otimes u) \otimes (1 \otimes v) \mapsto 1 \otimes (u \otimes v)$, for all $u \in M$ and all $v \in N$.

The proof uses identities from Proposition 33.13. It is not hard but it requires a little gymnastic; a good exercise for the reader.

Chapter 36

The Rational Canonical Form and Other Normal Forms

36.1 The Torsion Module Associated With An Endomorphism

We saw in Section 7.7 that given a linear map $f: E \rightarrow E$ from a K -vector space E into itself, we can define a scalar multiplication $\cdot: K[X] \times E \rightarrow E$ that makes E into a $K[X]$ -module. If E is finite-dimensional, this $K[X]$ -module denoted by E_f is a torsion module, and the main results of this chapter yield important direct sum decompositions of E into subspaces invariant under f .

Recall that given any polynomial $p(X) = a_0X^n + a_1X^{n-1} + \cdots + a_n$ with coefficients in the field K , we define the *linear map* $p(f): E \rightarrow E$ by

$$p(f) = a_0f^n + a_1f^{n-1} + \cdots + a_n\text{id},$$

where $f^k = f \circ \cdots \circ f$, the k -fold composition of f with itself. Note that

$$p(f)(u) = a_0f^n(u) + a_1f^{n-1}(u) + \cdots + a_nu,$$

for every vector $u \in E$. Then, we define the scalar multiplication $\cdot: K[X] \times E \rightarrow E$ by polynomials as follows: for every polynomial $p(X) \in K[X]$, for every $u \in E$,

$$p(X) \cdot u = p(f)(u).^1$$

It is easy to verify that this scalar multiplication satisfies the axioms M1, M2, M3, M4:

$$\begin{aligned} p \cdot (u + v) &= p \cdot u + p \cdot v \\ (p + q) \cdot u &= p \cdot u + q \cdot u \\ (pq) \cdot u &= p \cdot (q \cdot u) \\ 1 \cdot u &= u, \end{aligned}$$

¹If necessary to avoid confusion, we use the notion $p(X) \cdot_f u$ instead of $p(X) \cdot u$.

for all $p, q \in K[X]$ and all $u, v \in E$. Thus, with this new scalar multiplication, E is a $K[X]$ -module denoted by E_f .

If $p = \lambda$ is just a scalar in K (a polynomial of degree 0), then

$$\lambda \cdot u = (\lambda \text{id})(u) = \lambda u,$$

which means that K acts on E by scalar multiplication as before. If $p(X) = X$ (the monomial X), then

$$X \cdot u = f(u).$$

Since K is a field, the ring $K[X]$ is a PID.

If E is finite-dimensional, say of dimension n , since K is a subring of $K[X]$ and since E is finitely generated over K , the $K[X]$ -module E_f is finitely generated over $K[X]$. Furthermore, E_f is a torsion module. This follows from the Cayley-Hamilton Theorem (Theorem 7.15), but this can also be shown in an elementary fashion as follows. The space $\text{Hom}(E, E)$ of linear maps of E into itself is a vector space of dimension n^2 , therefore the $n^2 + 1$ linear maps

$$\text{id}, f, f^2, \dots, f^{n^2}$$

are linearly dependent, which yields a nonzero polynomial q such that $q(f) = 0$.

We can now translate notions defined for modules into notions for endomorphisms of vector spaces.

1. To say that U is a submodule of E_f means that U is a subspace of E invariant under f ; that is, $f(U) \subseteq U$.
2. To say that V is a cyclic submodule of E_f means that there is some vector $u \in V$, such that V is spanned by $(u, f(u), \dots, f^k(u), \dots)$. If E has finite dimension n , then V is spanned by $(u, f(u), \dots, f^k(u))$ for some $k \leq n - 1$. We say that V is a *cyclic subspace for f with generator u* . Sometimes, V is denoted by $Z(u; f)$.
3. To say that the ideal $\mathfrak{a} = (p(X))$ (with $p(X)$ a monic polynomial) is the annihilator of the submodule V means that $p(f)(u) = 0$ for all $u \in V$, and we call p the *minimal polynomial* of V .
4. Suppose E_f is cyclic and let $\mathfrak{a} = (q)$ be its annihilator, where

$$q(X) = X^n + a_{n-1}X^{n-1} + \cdots + a_1X + a_0.$$

Then, there is some vector u such that $(u, f(u), \dots, f^k(u))$ span E_f , and because q is the minimal polynomial of E_f , we must have $k = n - 1$. The fact that $q(f) = 0$ implies that

$$f^n(u) = -a_0u - a_1f(u) - \cdots - a_{n-1}f^{n-1}(u),$$

and so f is represented by the following matrix known as the *companion matrix* of $q(X)$:

$$U = \begin{pmatrix} 0 & 0 & 0 & \cdots & 0 & -a_0 \\ 1 & 0 & 0 & \cdots & 0 & -a_1 \\ 0 & 1 & 0 & \cdots & 0 & -a_2 \\ \vdots & \ddots & \ddots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \ddots & 0 & -a_{n-2} \\ 0 & 0 & 0 & \cdots & 1 & -a_{n-1} \end{pmatrix}.$$

It is an easy exercise to prove that the characteristic polynomial $\chi_U(X)$ of U gives back $q(X)$:

$$\chi_U(X) = q(X).$$

We will need the following proposition to characterize when two linear maps are similar.

Proposition 36.1. *Let $f: E \rightarrow E$ and $f': E' \rightarrow E'$ be two linear maps over the vector spaces E and E' . A linear map $g: E \rightarrow E'$ can be viewed as a linear map between the $K[X]$ -modules E_f and $E_{f'}$ iff*

$$g \circ f = f' \circ g.$$

Proof. First, suppose g is $K[X]$ -linear. Then, we have

$$g(p \cdot_f u) = p \cdot_{f'} g(u)$$

for all $p \in K[X]$ and all $u \in E$, so for $p = X$ we get

$$g(p \cdot_f u) = g(X \cdot_f u) = g(f(u))$$

and

$$p \cdot_{f'} g(u) = X \cdot_{f'} g(u) = f'(g(u)),$$

which means that $g \circ f = f' \circ g$.

Conversely, if $g \circ f = f' \circ g$, we prove by induction that

$$g \circ f^n = f'^n \circ g, \quad \text{for all } n \geq 1.$$

Indeed, we have

$$\begin{aligned} g \circ f^{n+1} &= g \circ f^n \circ f \\ &= f'^n \circ g \circ f \\ &= f'^n \circ f' \circ g \\ &= f'^{n+1} \circ g, \end{aligned}$$

establishing the induction step. It follows that for any polynomial $p(X) = \sum_{k=0}^n a_k X^k$, we have

$$\begin{aligned} g(p(X) \cdot_f u) &= g\left(\sum_{k=0}^n a_k f^k(u)\right) \\ &= \sum_{k=0}^n a_k g \circ f^k(u) \\ &= \sum_{k=0}^n a_k f'^k \circ g(u) \\ &= \left(\sum_{k=0}^n a_k f'^k\right)(g(u)) \\ &= p(X) \cdot_{f'} g(u), \end{aligned}$$

so, g is indeed $K[X]$ -linear. \square

Definition 36.1. We say that the linear maps $f: E \rightarrow E$ and $f': E' \rightarrow E'$ are *similar* iff there is an isomorphism $g: E \rightarrow E'$ such that

$$f' = g \circ f \circ g^{-1},$$

or equivalently,

$$g \circ f = f' \circ g.$$

Then, Proposition 36.1 shows the following fact:

Proposition 36.2. *With notation of Proposition 36.1, two linear maps f and f' are similar iff g is an isomorphism between E_f and $E'_{f'}$.*

Later on, we will see that the isomorphism of finitely generated torsion modules can be characterized in terms of invariant factors, and this will be translated into a characterization of similarity of linear maps in terms of so-called similarity invariants. If f and f' are represented by matrices A and A' over bases of E and E' , then f and f' are similar iff the matrices A and A' are similar (there is an invertible matrix P such that $A' = PAP^{-1}$). Similar matrices (and endomorphisms) have the same characteristic polynomial.

It turns out that there is a useful relationship between E_f and the module $K[X] \otimes_K E$. Observe that the map $\cdot: K[X] \times E \rightarrow E$ given by

$$p \cdot u = p(f)(u)$$

is K -bilinear, so it yields a K -linear map $\sigma: K[X] \otimes_K E \rightarrow E$ such that

$$\sigma(p \otimes u) = p \cdot u = p(f)(u).$$

We know from Section 35.6 that $K[X] \otimes_K E$ is a $K[X]$ -module (obtained from the inclusion $K \subseteq K[X]$), which we will denote by $E[X]$. Since E is a vector space, $E[X]$ is a free $K[X]$ -module, and if (u_1, \dots, u_n) is a basis of E , then $(1 \otimes u_1, \dots, 1 \otimes u_n)$ is a basis of $E[X]$.

The free $K[X]$ -module $E[X]$ is not as complicated as it looks. Over the basis $(1 \otimes u_1, \dots, 1 \otimes u_n)$, every element $z \in E[X]$ can be written uniquely as

$$z = p_1(1 \otimes u_1) + \cdots + p_n(1 \otimes u_n) = p_1 \otimes u_1 + \cdots + p_n \otimes u_n,$$

where p_1, \dots, p_n are polynomials in $K[X]$. For notational simplicity, we may write

$$z = p_1 u_1 + \cdots + p_n u_n,$$

where p_1, \dots, p_n are viewed as coefficients in $K[X]$. With this notation, we see that $E[X]$ is isomorphic to $(K[X])^n$, which is easy to understand.

Observe that σ is $K[X]$ -linear, because

$$\begin{aligned} \sigma(q(p \otimes u)) &= \sigma((qp) \otimes u) \\ &= (qp) \cdot u \\ &= q(f)(p(f)(u)) \\ &= q \cdot (p(f)(u)) \\ &= q \cdot \sigma(p \otimes u). \end{aligned}$$

Therefore, σ is a linear map of $K[X]$ -modules, $\sigma: E[X] \rightarrow E_f$. Using our simplified notation, if $z = p_1 u_1 + \cdots + p_n u_n \in E[X]$, then

$$\sigma(z) = p_1(f)(u_1) + \cdots + p_n(f)(u_n),$$

which amounts to plugging f for X and evaluating. Similarly, f is a $K[X]$ -linear map of E_f , because

$$\begin{aligned} f(p \cdot u) &= f(p(f)(u)) \\ &= (fp(f))(u) \\ &= p(f)(f(u)) \\ &= p \cdot f(u), \end{aligned}$$

where we used the fact that $fp(f) = p(f)f$ because $p(f)$ is a polynomial in f . By Proposition 35.40, the linear map $f: E \rightarrow E$ induces a $K[X]$ -linear map $\bar{f}: E[X] \rightarrow E[X]$ such that

$$\bar{f}(p \otimes u) = p \otimes f(u).$$

Observe that we have

$$f(\sigma(p \otimes u)) = f(p(f)(u)) = p(f)(f(u))$$

and

$$\sigma(\bar{f}(p \otimes u)) = \sigma(p \otimes f(u)) = p(f)(f(u)),$$

so we get

$$\sigma \circ \bar{f} = f \circ \sigma. \quad (*)$$

Using our simplified notation,

$$\bar{f}(p_1 u_1 + \cdots + p_n u_n) = p_1 f(u_1) + \cdots + p_n f(u_n).$$

Define the $K[X]$ -linear map $\psi: E[X] \rightarrow E[X]$ by

$$\psi(p \otimes u) = (Xp) \otimes u - p \otimes f(u).$$

Observe that $\psi = X1_{E[X]} - \bar{f}$, which we abbreviate as $X1 - \bar{f}$. Using our simplified notation

$$\psi(p_1 u_1 + \cdots + p_n u_n) = Xp_1 u_1 + \cdots + Xp_n u_n - (p_1 f(u_1) + \cdots + p_n f(u_n)).$$

It should be noted that everything we did in Section 36.1 applies to modules over a commutative ring A , except for the statements that assume that $A[X]$ is a PID. So, if M is an A -module, we can define the $A[X]$ -modules M_f and $M[X] = A[X] \otimes_A M$, except that M_f is generally not a torsion module, and all the results showed above hold. Then, we have the following remarkable result.

Theorem 36.3. (The Characteristic Sequence) *Let A be a ring and let E be an A -module. The following sequence of $A[X]$ -linear maps is exact:*

$$0 \longrightarrow E[X] \xrightarrow{\psi} E[X] \xrightarrow{\sigma} E_f \longrightarrow 0.$$

This means that ψ is injective, σ is surjective, and that $\text{Im}(\psi) = \text{Ker}(\sigma)$. As a consequence, E_f is isomorphic to the quotient of $E[X]$ by $\text{Im}(X1 - \bar{f})$.

Proof. Because $\sigma(1 \otimes u) = u$ for all $u \in E$, the map σ is surjective. We have

$$\begin{aligned} \sigma(X(p \otimes u)) &= X \cdot \sigma(p \otimes u) \\ &= f(\sigma(p \otimes u)), \end{aligned}$$

which shows that

$$\sigma \circ X1 = f \circ \sigma = \sigma \circ \bar{f},$$

using (*). This implies that

$$\begin{aligned} \sigma \circ \psi &= \sigma \circ (X1 - \bar{f}) \\ &= \sigma \circ X1 - \sigma \circ \bar{f} \\ &= \sigma \circ \bar{f} - \sigma \circ \bar{f} = 0, \end{aligned}$$

and thus, $\text{Im}(\psi) \subseteq \text{Ker}(\sigma)$. It remains to prove that $\text{Ker}(\sigma) \subseteq \text{Im}(\psi)$.

Since the monomials X^k form a basis of $A[X]$, by Proposition 35.13 (with the roles of M and N exchanged), every $z \in E[X] = A[X] \otimes_A E$ has a unique expression as

$$z = \sum_k X^k \otimes u_k,$$

for a family (u_k) of finite support of $u_k \in E$. If $z \in \text{Ker}(\sigma)$, then

$$0 = \sigma(z) = \sum_k f^k(u_k),$$

which allows us to write

$$\begin{aligned} z &= \sum_k X^k \otimes u_k - 1 \otimes 0 \\ &= \sum_k X^k \otimes u_k - 1 \otimes \left(\sum_k f^k(u_k) \right) \\ &= \sum_k (X^k \otimes u_k - 1 \otimes f^k(u_k)) \\ &= \sum_k (X^k(1 \otimes u_k) - \bar{f}^k(1 \otimes u_k)) \\ &= \sum_k (X^k 1 - \bar{f}^k)(1 \otimes u_k). \end{aligned}$$

Now, $X1$ and \bar{f} commute, since

$$\begin{aligned} (X1 \circ \bar{f})(p \otimes u) &= (X1)(p \otimes f(u)) \\ &= (Xp) \otimes f(u) \end{aligned}$$

and

$$\begin{aligned} (\bar{f} \circ X1)(p \otimes u) &= \bar{f}((Xp) \otimes u) \\ &= (Xp) \otimes f(u), \end{aligned}$$

so we can write

$$X^k 1 - \bar{f}^k = (X1 - \bar{f}) \left(\sum_{j=0}^{k-1} (X1)^j \bar{f}^{k-j-1} \right),$$

and

$$z = (X1 - \bar{f}) \left(\sum_k \left(\sum_{j=0}^{k-1} (X1)^j \bar{f}^{k-j-1} \right) (1 \otimes u_k) \right),$$

which shows that $z = \psi(y)$ for some $y \in E[X]$.

Finally, we prove that ψ is injective as follows. We have

$$\begin{aligned}\psi(z) &= \psi\left(\sum_k X^k \otimes u_k\right) \\ &= (X1 - \bar{f})\left(\sum_k X^k \otimes u_k\right) \\ &= \sum_k X^{k+1} \otimes (u_k - f(u_{k+1})),\end{aligned}$$

where (u_k) is a family of finite support of $u_k \in E$. If $\psi(z) = 0$, then

$$\sum_k X^{k+1} \otimes (u_k - f(u_{k+1})) = 0,$$

and because the X^k form a basis of $A[X]$, we must have

$$u_k - f(u_{k+1}) = 0, \quad \text{for all } k.$$

Since (u_k) has finite support, there is a largest k , say $m + 1$ so that $u_{m+1} = 0$, and then from

$$u_k = f(u_{k+1}),$$

we deduce that $u_k = 0$ for all k . Therefore, $z = 0$, and ψ is injective. \square

Remark: The exact sequence of Theorem 36.3 yields a *presentation* of M_f .

Since $A[X]$ is a free A -module, $A[X] \otimes_A M$ is a free A -module, but $A[X] \otimes_A M$ is generally not a free $A[X]$ -module. However, if M is a free module, then $M[X]$ is a free $A[X]$ -module, since if $(u_i)_{i \in I}$ is a basis for M , then $(1 \otimes u_i)_{i \in I}$ is a basis for $M[X]$. This allows us to define the characteristic polynomial $\chi_f(X)$ of an endomorphism of a free module M as

$$\chi_f(X) = \det(X1 - \bar{f}).$$

Note that to have a correct definition, we need to define the determinant of a linear map allowing the indeterminate X as a scalar, and this is what the definition of $M[X]$ achieves (among other things). Theorem 36.3 can be used to give a short proof of the Cayley-Hamilton Theorem, see Bourbaki [25] (Chapter III, Section 8, Proposition 20). Proposition 7.10 is still the crucial ingredient of the proof.

36.2 The Rational Canonical Form

Let E be a finite-dimensional vector space over a field K , and let $f: E \rightarrow E$ be an endomorphism of E . We know from Section 36.1 that there is a $K[X]$ -module E_f associated with f , and that E_f is a finitely generated torsion module over the PID $K[X]$. In this chapter, we show how Theorems from Sections 35.4 and 35.5 yield important results about the structure of the linear map f .

Recall that the annihilator of a subspace V is an ideal (p) uniquely defined by a monic polynomial p called the *minimal polynomial* of V .

Our first result is obtained by translating the primary decomposition theorem, Theorem 35.19. It is not too surprising that we obtain again Theorem 31.10!

Theorem 36.4. (*Primary Decomposition Theorem*) *Let $f: E \rightarrow E$ be a linear map on the finite-dimensional vector space E over the field K . Write the minimal polynomial m of f as*

$$m = p_1^{r_1} \cdots p_k^{r_k},$$

where the p_i are distinct irreducible monic polynomials over K , and the r_i are positive integers. Let

$$W_i = \text{Ker}(p_i(f)^{r_i}), \quad i = 1, \dots, k.$$

Then

- (a) $E = W_1 \oplus \cdots \oplus W_k$.
- (b) Each W_i is invariant under f and the projection from E onto W_i is given by a polynomial in f .
- (c) The minimal polynomial of the restriction $f|_{W_i}$ of f to W_i is $p_i^{r_i}$.

Example 36.1. Let $f: \mathbb{R}^4 \rightarrow \mathbb{R}^4$ be defined as $f(x, y, z, w) = (x + w, y + z, y + z, x + w)$. In terms of the standard basis, f has the matrix representation

$$M = \begin{pmatrix} 1 & 0 & 0 & 1 \\ 0 & 1 & 1 & 0 \\ 0 & 1 & 1 & 0 \\ 1 & 0 & 0 & 1 \end{pmatrix}.$$

A basic calculation shows that $\chi_f(X) = X^2(X - 2)^2$ and that $m_f(X) = X(X - 2)$. The primary decomposition theorem implies that

$$\mathbb{R}^4 = W_1 \oplus W_2, \quad W_1 = \text{Ker}(M), \quad W_2 = \text{Ker}(M - 2I).$$

Note that $\text{Ker}(M)$ corresponds to the eigenspace associated with eigenvalue 0 and has basis $([-1, 0, 0, 1], [0, -1, 1, 0])$, while $\text{Ker}(M - 2I)$ corresponds to the eigenspace associated with eigenvalue 2 and has basis $([1, 0, 0, 1], [0, 1, 1, 0])$.

Next we apply the Invariant Factors Decomposition Theorem, Theorem 35.31, to E_f . This theorem says that E_f is isomorphic to a direct sum

$$E_f \approx K[X]/(p_1) \oplus \cdots \oplus K[X]/(p_m)$$

of $m \leq n$ cyclic modules, where the p_j are uniquely determined monic polynomials of degree at least 1, such that

$$p_m \mid p_{m-1} \mid \cdots \mid p_1.$$

Each cyclic module $K[X]/(p_i)$ is isomorphic to a cyclic subspace for f , say V_i , whose minimal polynomial is p_i .

It is customary to renumber the polynomials p_i as follows. The n polynomials q_1, \dots, q_n are defined by:

$$q_j(X) = \begin{cases} 1 & \text{if } 1 \leq j \leq n-m \\ p_{n-j+1}(X) & \text{if } n-m+1 \leq j \leq n. \end{cases}$$

Then we see that

$$q_1 \mid q_2 \mid \cdots \mid q_n,$$

where the first $n-m$ polynomials are equal to 1, and we have the direct sum

$$E = E_1 \oplus \cdots \oplus E_n,$$

where E_i is a cyclic subspace for f whose minimal polynomial is q_i . In particular, $E_i = (0)$ for $i = 1, \dots, n-m$. Theorem 35.31 also says that the minimal polynomial of f is $q_n = p_1$. We sum all this up in the following theorem.

Theorem 36.5. (Cyclic Decomposition Theorem, First Version) *Let $f: E \rightarrow E$ be an endomorphism on a K -vector space of dimension n . There exist n monic polynomials $q_1, \dots, q_n \in K[X]$ such that*

$$q_1 \mid q_2 \mid \cdots \mid q_n,$$

and E is the direct sum

$$E = E_1 \oplus \cdots \oplus E_n$$

of cyclic subspaces $E_i = Z(u_i; f)$ for f , such that the minimal polynomial of the restriction of f to E_i is q_i . The polynomials q_i satisfying the above conditions are unique, and q_n is the minimal polynomial of f .

In view of translation point (4) at the beginning of Section 36.1, we know that over the basis

$$(u_i, f(u_i), \dots, f^{n_i-1}(u_i))$$

of the cyclic subspace $E_i = Z(u_i; f)$, with $n_i = \deg(q_i)$, the matrix of the restriction of f to E_i is the *companion matrix* of $p_i(X)$, of the form

$$\begin{pmatrix} 0 & 0 & 0 & \cdots & 0 & -a_0 \\ 1 & 0 & 0 & \cdots & 0 & -a_1 \\ 0 & 1 & 0 & \cdots & 0 & -a_2 \\ \vdots & \ddots & \ddots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \ddots & 0 & -a_{n_i-2} \\ 0 & 0 & 0 & \cdots & 1 & -a_{n_i-1} \end{pmatrix}.$$

If we put all these bases together, we obtain a block matrix whose blocks are of the above form. Therefore, we proved the following result.

Theorem 36.6. (*Rational Canonical Form, First Version*) *Let $f: E \rightarrow E$ be an endomorphism on a K -vector space of dimension n . There exist n monic polynomials $q_1, \dots, q_n \in K[X]$ such that*

$$q_1 \mid q_2 \mid \cdots \mid q_n,$$

with $q_1 = \cdots = q_{n-m} = 1$, and a basis of E such that the matrix M of f is a block matrix of the form

$$M = \begin{pmatrix} M_{n-m+1} & 0 & \cdots & 0 & 0 \\ 0 & M_{n-m+2} & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & M_{n-1} & 0 \\ 0 & 0 & \cdots & 0 & M_n \end{pmatrix},$$

where each M_i is the companion matrix of q_i . The polynomials q_i satisfying the above conditions are unique, and q_n is the minimal polynomial of f .

Definition 36.2. A matrix M as in Theorem 36.6 is called a matrix in *rational form*. The polynomials q_1, \dots, q_n arising in Theorems 36.5 and 36.6 are called the *similarity invariants* (or *invariant factors*) of f .

Theorem 36.6 shows that every matrix is similar to a matrix in rational form. Such a matrix is unique.

Example 1 continued: We will calculate the rational canonical form for $f(x, y, z, w) = (x + w, y + z, y + z, x + w)$. The difficulty in finding the rational canonical form lies in determining the invariant factors q_1, q_2, q_3, q_4 . As we will shortly discover, the invariant factors of f correspond to the invariant factors of $XI - M$. See Propositions 36.8 and 36.11. The invariant factors of $XI - M$ are found by converting $XI - M$ to Smith normal form. Section 36.5 describes an algorithmic procedure for computing the Smith normal form of a matrix. By applying the methodology of Section 36.5, we find that Smith normal form for

$XI - M$ is

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & X(X-2) & 0 \\ 0 & 0 & 0 & X(X-2) \end{pmatrix}.$$

Thus the invariant factors of f are $q_1 = 1 = q_2$, $q_3 = X(X-2) = q_4$, and Theorem 36.5 implies that

$$\mathbb{R}^4 = E_1 \oplus E_2,$$

where $E_1 = Z(u_1, f) \cong \mathbb{R}[X]/(X(X-2))$ and $E_2 = Z(u_2, f) \cong \mathbb{R}[X]/(X(X-2))$. The subspace E_1 has basis (u_1, Mu_1) where $u_1 = (1, 0, 1, 0)$ and $Mu_1 = (1, 1, 1, 1)$, while the subspace E_2 has basis (u_2, Mu_2) where $u_2 = (0, 0, 1, 0)$ and $Mu_2 = (0, 1, 1, 0)$. Theorem 36.6 implies that rational canonical form of $M(f)$ is

$$\begin{pmatrix} 0 & 0 & 0 & 0 \\ 1 & 2 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 2 \end{pmatrix}.$$

By Proposition 36.2, two linear maps f and f' are similar iff there is an isomorphism between E_f and $E'_{f'}$, and thus by the uniqueness part of Theorem 35.31, iff they have the same similarity invariants q_1, \dots, q_n .

Proposition 36.7. *If E and E' are two finite-dimensional vector spaces and if $f: E \rightarrow E$ and $f': E' \rightarrow E'$ are two linear maps, then f and f' are similar iff they have the same similarity invariants.*

The effect of extending the field K to a field L is the object of the next proposition.

Proposition 36.8. *Let $f: E \rightarrow E$ be a linear map on a K -vector space E , and let (q_1, \dots, q_n) be the similarity invariants of f . If L is a field extension of K (which means that $K \subseteq L$), and if $E_{(L)} = L \otimes_K E$ is the vector space obtained by extending the scalars, and $f_{(L)} = 1_L \otimes f$ the linear map of $E_{(L)}$ induced by f , then the similarity invariants of $f_{(L)}$ are (q_1, \dots, q_n) viewed as polynomials in $L[X]$.*

Proof. We know that E_f is isomorphic to the direct sum

$$E_f \approx K[X]/(q_1 K[X]) \oplus \cdots \oplus K[X]/(q_n K[X]),$$

so by tensoring with $L[X]$ and using Propositions 35.12 and 33.13, we get

$$\begin{aligned} L[X] \otimes_{K[X]} E_f &\approx L[X] \otimes_{K[X]} (K[X]/(q_1 K[X]) \oplus \cdots \oplus K[X]/(q_n K[X])) \\ &\approx L[X] \otimes_{K[X]} (K[X]/(q_1 K[X])) \oplus \cdots \oplus L[X] \otimes_{K[X]} (K[X]/(q_n K[X])) \\ &\approx (K[X]/(q_1 K[X])) \otimes_{K[X]} L[X] \oplus \cdots \oplus (K[X]/(q_n K[X])) \otimes_{K[X]} L[X]. \end{aligned}$$

However, by Proposition 35.14, we have isomorphisms

$$(K[X]/(q_i K[X])) \otimes_{K[X]} L[X] \approx L[X]/(q_i L[X]),$$

so we get

$$L[X] \otimes_{K[X]} E_f \approx L[X]/(q_1 L[X]) \oplus \cdots \oplus L[X]/(q_n L[X]).$$

Since E_f is a $K[X]$ -module, the $L[X]$ module $L[X] \otimes_{K[X]} E_f$ is the module obtained from E_f by the ring extension $K[X] \subseteq L[X]$. The L -module $E_{(L)} = L \otimes_K E$ becomes the $L[X]$ -module $E_{(L)f_{(L)}}$ where

$$f_{(L)} = \text{id}_L \otimes_K f.$$

We have the following proposition

Proposition 36.9. *For any field extension $K \subseteq L$, and any linear map $f: E \rightarrow E$ where E is a K -vector space, there is an isomorphism between the $L[X]$ -modules $L[X] \otimes_{K[X]} E_f$ and $E_{(L)f_{(L)}}$.*

Proof. First we define the map $\alpha: L \times E \rightarrow L[X] \otimes_{K[X]} E_f$ by

$$\alpha(\lambda, u) = \lambda \otimes_{K[X]} u.$$

It is immediately verified that α is K -bilinear, so we obtain a K -linear map $\tilde{\alpha}: L \otimes_K E \rightarrow L[X] \otimes_{K[X]} E_f$. Now $E_{(L)} = L \otimes_K E$ is a $L[X]$ -module $(L \otimes_K E)_{f(L)}$, and let us denote this scalar multiplication by \odot . To describe \odot it is enough to define how a monomial $aX^k \in L[X]$ acts on a generator $(\lambda \otimes_K u) \in L \otimes_K E$. We have

$$\begin{aligned} aX^k \odot (\lambda \otimes_K u) &= a(\text{id}_L \otimes_K f)^k(\lambda \otimes_K u) \\ &= a(\lambda \otimes_K f^k(u)) \\ &= a\lambda \otimes_K f^k(u). \end{aligned}$$

We claim that $\tilde{\alpha}$ is actually $L[X]$ -linear. Indeed, we have

$$\begin{aligned} \tilde{\alpha}(aX^k \odot (\lambda \otimes_K u)) &= \tilde{\alpha}(a\lambda \otimes_K f^k(u)) \\ &= a\lambda \otimes_{K[X]} f^k(u), \end{aligned}$$

and by the definition of scalar multiplication in the $K[X]$ -module E_f , we have $f^k(u) = X^k \cdot_f u$, so we have

$$\begin{aligned} \tilde{\alpha}(aX^k \odot (\lambda \otimes_K u)) &= a\lambda \otimes_{K[X]} f^k(u) \\ &= a\lambda \otimes_{K[X]} X^k \cdot_f u \\ &= X^k \cdot (a\lambda \otimes_{K[X]} u) \\ &= aX^k \cdot (\lambda \otimes_{K[X]} u), \end{aligned}$$

which shows that $\tilde{\alpha}$ is $L[X]$ -linear.

We also define the map $\beta: L[X] \times E_f \rightarrow (L \otimes_K E)_{f(L)}$ by

$$\beta(q(X), u) = q(X) \odot (1 \otimes_K u).$$

Using a computation similar to the computation that we just performed, we can check that β is $K[X]$ -bilinear so we obtain a map $\tilde{\beta}: L[X] \otimes_{K[X]} E_f \rightarrow (L \otimes_K E)_{f(L)}$. To finish the proof, it suffices to prove that $\tilde{\alpha} \circ \tilde{\beta}$ and $\tilde{\beta} \circ \tilde{\alpha}$ are the identity on generators. We have

$$\tilde{\alpha} \circ \tilde{\beta}(q(X) \otimes_{K[X]} u) = \tilde{\alpha}(q(X) \odot (1 \otimes_K u)) = q(X) \cdot (1 \otimes_{K[X]} u) = q(X) \otimes_{K[X]} u,$$

and

$$\tilde{\beta} \circ \tilde{\alpha}(\lambda \otimes_K u) = \tilde{\beta}(\lambda \otimes_{K[X]} u) = \lambda \odot (1 \otimes_K u) = \lambda \otimes_K u,$$

which finishes the proof. \square

By Proposition 36.9,

$$E_{(L)f(L)} \approx L[X] \otimes_{K[X]} E_f \approx L[X]/(q_1 L[X]) \oplus \cdots \oplus L[X]/(q_n L[X]),$$

which shows that (q_1, \dots, q_n) are the similarity invariants of $f_{(L)}$. \square

Proposition 36.8 justifies the terminology “invariant” in similarity invariants. Indeed, under a field extension $K \subseteq L$, the similarity invariants of $f_{(L)}$ remain the same. This is not true of the elementary divisors, which depend on the field; indeed, an irreducible polynomial $p \in K[X]$ may split over $L[X]$. Since q_n is the minimal polynomial of f , the above reasoning also shows that the minimal polynomial of $f_{(L)}$ remains the same under a field extension.

Proposition 36.8 has the following corollary.

Proposition 36.10. *Let K be a field and let $L \supseteq K$ be a field extension of K . For any two square matrices A and B over K , if there is an invertible matrix Q over L such that $B = QAQ^{-1}$, then there is an invertible matrix P over K such that $B = PAP^{-1}$.*

Recall from Theorem 36.3 that the sequence of $K[X]$ -linear maps

$$0 \longrightarrow E[X] \xrightarrow{\psi} E[X] \xrightarrow{\sigma} E_f \longrightarrow 0$$

is exact, and as a consequence, E_f is isomorphic to the quotient of $E[X]$ by $\text{Im}(X1 - \bar{f})$. Furthermore, because E is a vector space, $E[X]$ is a free module with basis $(1 \otimes u_1, \dots, 1 \otimes u_n)$, where (u_1, \dots, u_n) is a basis of E , and since ψ is injective, the module $\text{Im}(X1 - \bar{f})$ has rank n . By Theorem 35.31, we have an isomorphism

$$E_f \approx K[X]/(q_1 K[X]) \oplus \cdots \oplus K[X]/(q_n K[X]),$$

and by Proposition 35.32, $E[X]/\text{Im}(X1 - \bar{f})$ is isomorphic to a direct sum

$$E[X]/\text{Im}(X1 - \bar{f}) \approx K[X]/(p_1 K[X]) \oplus \cdots \oplus K[X]/(p_n K[X]),$$

where p_1, \dots, p_n are the invariant factors of $\text{Im}(X\mathbf{1} - \bar{f})$ with respect to $E[X]$. Since $E_f \approx E[X]/\text{Im}(X\mathbf{1} - \bar{f})$, by the uniqueness part of Theorem 35.31 and because the polynomials are monic, we must have $p_i = q_i$, for $i = 1, \dots, n$. Therefore, we proved the following crucial fact:

Proposition 36.11. *For any linear map $f: E \rightarrow E$ over a K -vector space E of dimension n , the similarity invariants of f are equal to the invariant factors of $\text{Im}(X\mathbf{1} - \bar{f})$ with respect to $E[X]$.*

Proposition 36.11 is the key to computing the similarity invariants of a linear map. This can be done using a procedure to convert $XI - M$ to its *Smith normal form*. Propositions 36.11 and 35.37 yield the following result.

Proposition 36.12. *For any linear map $f: E \rightarrow E$ over a K -vector space E of dimension n , if (q_1, \dots, q_n) are the similarity invariants of f , for any matrix M representing f with respect to any basis, then for $k = 1, \dots, n$ the product*

$$d_k(X) = q_1(X) \cdots q_k(X)$$

is the gcd of the $k \times k$ -minors of the matrix $XI - M$.

Note that the matrix $XI - M$ is none other than the matrix that yields the characteristic polynomial $\chi_f(X) = \det(XI - M)$ of f .

Proposition 36.13. *For any linear map $f: E \rightarrow E$ over a K -vector space E of dimension n , if (q_1, \dots, q_n) are the similarity invariants of f , then the following properties hold:*

(1) *If $\chi_f(X)$ is the characteristic polynomial of f , then*

$$\chi_f(X) = q_1(X) \cdots q_n(X).$$

(2) *The minimal polynomial $m(X) = q_n(X)$ of f divides the characteristic polynomial $\chi_f(X)$ of f .*

(3) *The characteristic polynomial $\chi_f(X)$ divides $m(X)^n$.*

(4) *E is cyclic for f iff $m(X) = \chi_f(X)$.*

Proof. Property (1) follows from Proposition 36.12 for $k = n$. It also follows from Theorem 36.6 and the fact that for the companion matrix associated with q_i , the characteristic polynomial of this matrix is also q_i . Property (2) is obvious from (1). Since each q_i divides q_{i+1} , each q_i divides q_n , so their product $\chi_f(X)$ divides $m(X)^n = q_n(X)^n$. The last condition says that $q_1 = \cdots = q_{n-1} = 1$, which means that E_f has a single summand. \square

Observe that Proposition 36.13 yields another proof of the Cayley–Hamilton Theorem. It also implies that a linear map is nilpotent iff its characteristic polynomial is X^n .

36.3 The Rational Canonical Form, Second Version

Let us now translate the Elementary Divisors Decomposition Theorem, Theorem 35.38, in terms of E_f . We obtain the following result.

Theorem 36.14. (*Cyclic Decomposition Theorem, Second Version*) Let $f: E \rightarrow E$ be an endomorphism on a K -vector space of dimension n . Then, E is the direct sum of cyclic subspaces $E_j = Z(u_j; f)$ for f , such that the minimal polynomial of E_j is of the form $p_i^{n_{i,j}}$, for some irreducible monic polynomials $p_1, \dots, p_t \in K[X]$ and some positive integers $n_{i,j}$, such that for each $i = 1, \dots, t$, there is a sequence of integers

$$1 \leq \underbrace{n_{i,1}, \dots, n_{i,1}}_{m_{i,1}} < \underbrace{n_{i,2}, \dots, n_{i,2}}_{m_{i,2}} < \cdots < \underbrace{n_{i,s_i}, \dots, n_{i,s_i}}_{m_{i,s_i}},$$

with $s_i \geq 1$, and where $n_{i,j}$ occurs $m_{i,j} \geq 1$ times, for $j = 1, \dots, s_i$. Furthermore, the monic polynomials p_i and the integers $r, t, n_{i,j}, s_i, m_{i,j}$ are uniquely determined.

Note that there are $\mu = \sum m_{i,j}$ cyclic subspaces $Z(u_j; f)$. Using bases for the cyclic subspaces $Z(u_j; f)$ as in Theorem 36.6, we get the following theorem.

Theorem 36.15. (*Rational Canonical Form, Second Version*) Let $f: E \rightarrow E$ be an endomorphism on a K -vector space of dimension n . There exist t distinct irreducible monic polynomials $p_1, \dots, p_t \in K[X]$ and some positive integers $n_{i,j}$, such that for each $i = 1, \dots, t$, there is a sequence of integers

$$1 \leq \underbrace{n_{i,1}, \dots, n_{i,1}}_{m_{i,1}} < \underbrace{n_{i,2}, \dots, n_{i,2}}_{m_{i,2}} < \cdots < \underbrace{n_{i,s_i}, \dots, n_{i,s_i}}_{m_{i,s_i}},$$

with $s_i \geq 1$, and where $n_{i,j}$ occurs $m_{i,j} \geq 1$ times, for $j = 1, \dots, s_i$, and there is a basis of E such that the matrix M of f is a block matrix of the form

$$M = \begin{pmatrix} M_1 & 0 & \cdots & 0 & 0 \\ 0 & M_2 & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & M_{\mu-1} & 0 \\ 0 & 0 & \cdots & 0 & M_\mu \end{pmatrix},$$

where each M_j is the companion matrix of some $p_i^{n_{i,j}}$, and $\mu = \sum m_{i,j}$. The monic polynomials p_1, \dots, p_t and the integers $r, t, n_{i,j}, s_i, m_{i,j}$ are uniquely determined

The polynomials $p_i^{n_{i,j}}$ are called the *elementary divisors* of f (and M). These polynomials are factors of the minimal polynomial.

Example 1 continued: Recall that $f(x, y, z, w) = (x + w, y + z, y + z, x + w)$ has two nontrivial invariant factors $q_1 = x(x - 2) = q_2$. Thus the elementary factors of f are $p_1 = x = p_2$ and $p_3 = x - 2 = p_4$. Theorem 36.14 implies that

$$\mathbb{R}^4 = E_1 \oplus E_2 \oplus E_3 \oplus E_4,$$

where $E_1 = Z(u_1, f) \cong \mathbb{R}[X]/(X)$, $E_2 = Z(u_2, f) \cong \mathbb{R}[X]/(X)$, $E_3 = Z(u_3, f) \cong \mathbb{R}[X]/(X - 2)$, and $E_4 = Z(u_4, f) \cong \mathbb{R}[X]/(X - 2)$. The subspaces E_1 and E_2 correspond to one-dimensional spaces spanned by eigenvectors associated with eigenvalue 0, while E_3 and E_4 correspond to one-dimensional spaces spanned by eigenvectors associated with eigenvalue 2. If we let $u_1 = (-1, 0, 0, 1)$, $u_2 = (0, -1, 1, 0)$, $u_3 = (1, 0, 0, 1)$ and $u_4 = (0, 1, 1, 0)$, Theorem 36.15 gives

$$\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 2 \end{pmatrix},$$

as the rational canonical form associated with the cyclic decomposition $\mathbb{R}^4 = E_1 \oplus E_2 \oplus E_3 \oplus E_4$.

As we pointed earlier, unlike the similarity invariants, the elementary divisors may change when we pass to a field extension.

We will now consider the special case where all the irreducible polynomials p_i are of the form $X - \lambda_i$; that is, when the eigenvalues of f belong to K . In this case, we find again the Jordan form.

36.4 The Jordan Form Revisited

In this section, we assume that all the roots of the minimal polynomial of f belong to K . This will be the case if K is algebraically closed. The irreducible polynomials p_i of Theorem 36.14 are the polynomials $X - \lambda_i$, for the distinct eigenvalues λ_i of f . Then, each cyclic subspace $Z(u_j; f)$ has a minimal polynomial of the form $(X - \lambda)^m$, for some eigenvalue λ of f and some $m \geq 1$. It turns out that by choosing a suitable basis for the cyclic subspace $Z(u_j; f)$, the matrix of the restriction of f to $Z(u_j; f)$ is a Jordan block.

Proposition 36.16. *Let E be a finite-dimensional K -vector space and let $f: E \rightarrow E$ be a linear map. If E is a cyclic $K[X]$ -module and if $(X - \lambda)^n$ is the minimal polynomial of f , then there is a basis of E of the form*

$$((f - \lambda \text{id})^{n-1}(u), (f - \lambda \text{id})^{n-2}(u), \dots, (f - \lambda \text{id})(u), u),$$

for some $u \in E$. With respect to this basis, the matrix of f is the Jordan block

$$J_n(\lambda) = \begin{pmatrix} \lambda & 1 & 0 & \cdots & 0 \\ 0 & \lambda & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & 0 & \ddots & 1 \\ 0 & 0 & 0 & \cdots & \lambda \end{pmatrix}.$$

Proof. Since E is a cyclic $K[X]$ -module, there is some $u \in E$ so that E is generated by $u, f(u), f^2(u), \dots$, which means that every vector in E is of the form $p(f)(u)$, for some polynomial, $p(X)$. We claim that $u, f(u), \dots, f^{n-2}(u), f^{n-1}(u)$ generate E , which implies that the dimension of E is at most n .

This is because if $p(X)$ is any polynomial of degree at least n , then we can divide $p(X)$ by $(X - \lambda)^n$, obtaining

$$p = (X - \lambda)^n q + r,$$

where $0 \leq \deg(r) < n$, and as $(X - \lambda)^n$ annihilates E , we get

$$p(f)(u) = r(f)(u),$$

which means that every vector of the form $p(f)(u)$ with $p(X)$ of degree $\geq n$ is actually a linear combination of $u, f(u), \dots, f^{n-2}(u), f^{n-1}(u)$.

We claim that the vectors

$$u, (f - \lambda \text{id})(u), \dots, (f - \lambda \text{id})^{n-2}(u), (f - \lambda \text{id})^{n-1}(u)$$

are linearly independent. Indeed, if we had a nontrivial linear combination

$$a_0(f - \lambda \text{id})^{n-1}(u) + a_1(f - \lambda \text{id})^{n-2}(u) + \dots + a_{n-2}(f - \lambda \text{id})(u) + a_{n-1}u = 0,$$

then the polynomial

$$a_0(X - \lambda)^{n-1} + a_1(X - \lambda)^{n-2} + \dots + a_{n-2}(X - \lambda) + a_{n-1}$$

of degree at most $n - 1$ would annihilate E , contradicting the fact that $(X - \lambda)^n$ is the minimal polynomial of f (and thus, of smallest degree). Consequently, as the dimension of E is at most n ,

$$((f - \lambda \text{id})^{n-1}(u), (f - \lambda \text{id})^{n-2}(u), \dots, (f - \lambda \text{id})(u), u),$$

is a basis of E and since $u, f(u), \dots, f^{n-2}(u), f^{n-1}(u)$ span E ,

$$(u, f(u), \dots, f^{n-2}(u), f^{n-1}(u))$$

is also a basis of E .

Let us see how f acts on the basis

$$((f - \lambda \text{id})^{n-1}(u), (f - \lambda \text{id})^{n-2}(u), \dots, (f - \lambda \text{id})(u), u).$$

If we write $f = f - \lambda \text{id} + \lambda \text{id}$, as $(f - \lambda \text{id})^n$ annihilates E , we get

$$f((f - \lambda \text{id})^{n-1}(u)) = (f - \lambda \text{id})^n(u) + \lambda(f - \lambda \text{id})^{n-1}(u) = \lambda(f - \lambda \text{id})^{n-1}(u)$$

and

$$f((f - \lambda \text{id})^k(u)) = (f - \lambda \text{id})^{k+1}(u) + \lambda(f - \lambda \text{id})^k(u), \quad 0 \leq k \leq n - 2.$$

But this means precisely that the matrix of f in this basis is the Jordan block $J_n(\lambda)$. \square

The basis

$$((f - \lambda \text{id})^{n-1}(u), (f - \lambda \text{id})^{n-2}(u), \dots, (f - \lambda \text{id})(u), u),$$

provided by Proposition 36.16 is known as a *Jordan chain*. Note that $(f - \lambda \text{id})^{n-1}(u)$ is an eigenvector for f . To construct the Jordan chain, we must find u which is a generalized eigenvector of f . This is done by first finding an eigenvector x_1 of f and recursively solving the system $(f - \lambda \text{id})x_{i+1} = x_i$ for $i \leq 1 \leq n-1$. For example suppose $f: \mathbb{R}^3 \rightarrow \mathbb{R}^3$ where $f(x, y, z) = (x + y + z, y + z, z)$. In terms of the standard basis, the matrix representation

for f is $M = \begin{pmatrix} 1 & 1 & 1 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{pmatrix}$. By using M , it is readily verified that the minimal polynomial

f equals the characteristic polynomial, namely $(X - 1)^3$. Thus f has the eigenvalue $\lambda = 1$ with repeated three times. To find the eigenvector x_1 associated with $\lambda = 1$, we solve the system $(M - I)x_1 = 0$, or equivalently

$$\begin{pmatrix} 0 & 1 & 1 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}.$$

Thus $y = z = 0$ with $x = 1$ solves this system to provide the eigenvector $x_1 = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}$. We next solve the system $(M - I)x_2 = x_1$, namely

$$\begin{pmatrix} 0 & 1 & 1 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix},$$

which implies that $z = 0$ and $y = 1$. Hence $x_2 = \begin{pmatrix} 1 \\ 1 \\ 0 \end{pmatrix}$ will work. To finish constructing our Jordan chain, we must solve the system $(M - I)x_3 = x_2$, namely

$$\begin{pmatrix} 0 & 1 & 1 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} 1 \\ 1 \\ 0 \end{pmatrix},$$

from which we see that $z = 1$, $y = 0$, and $x_3 = \begin{pmatrix} 1 \\ 0 \\ 1 \end{pmatrix}$. By setting $x_3 = u$, we form the basis

$$((f - \lambda \text{id})^2(u), (f - \lambda \text{id})^1(u), \dots, (f - \lambda \text{id})(u), u) = (x_1, x_2, x_3).$$

In terms of the basis (x_1, x_2, x_3) , the map $f(x, y, z) = (x + y + z, y + z, z)$ has the Jordan block matrix representation $\begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{pmatrix}$ since

$$\begin{aligned} f(x_1) &= f(1, 0, 0) = (1, 0, 0) = x_1 \\ f(x_2) &= f(1, 1, 0) = (2, 1, 0) = x_1 + x_2 \\ f(x_3) &= f(1, 0, 1) = (2, 1, 1) = x_2 + x_3. \end{aligned}$$

Combining Theorem 36.15 and Proposition 36.16, we obtain a strong version of the Jordan form.

Theorem 36.17. (Jordan Canonical Form) *Let E be finite-dimensional K -vector space. The following properties are equivalent:*

- (1) *The eigenvalues of f all belong to K .*
- (2) *There is a basis of E in which the matrix of f is upper (or lower) triangular.*
- (3) *There exist a basis of E in which the matrix A of f is Jordan matrix. Furthermore, the number of Jordan blocks $J_r(\lambda)$ appearing in A , for fixed r and λ , is uniquely determined by f .*

Proof. The implication (1) \implies (3) follows from Theorem 36.15 and Proposition 36.16. The implications (3) \implies (2) and (2) \implies (1) are trivial. \square

Compared to Theorem 31.17, the new ingredient is the uniqueness assertion in (3), which is not so easy to prove.

Observe that the minimal polynomial of f is the least common multiple of the polynomials $(X - \lambda)^r$ associated with the Jordan blocks $J_r(\lambda)$ appearing in A , and the characteristic polynomial of A is the product of these polynomials.

We now return to the problem of computing effectively the similarity invariants of a matrix M . By Proposition 36.11, this is equivalent to computing the invariant factors of $XI - M$. In principle, this can be done using Proposition 35.35. A procedure to do this effectively for the ring $A = K[X]$ is to convert $XI - M$ to its Smith normal form. This will also yield the rational canonical form for M .

36.5 The Smith Normal Form

The Smith normal form is the special case of Proposition 35.35 applied to the PID $K[X]$ where K is a field, but it also says that the matrices P and Q are products of elementary matrices. It turns out that such a result holds for any Euclidean ring, and the proof is basically the same.

Recall from Definition 30.10 that a *Euclidean ring* is an integral domain A such that there exists a function $\sigma: A \rightarrow \mathbb{N}$ with the following property: For all $a, b \in A$ with $b \neq 0$, there are some $q, r \in A$ such that

$$a = bq + r \quad \text{and} \quad \sigma(r) < \sigma(b).$$

Note that the pair (q, r) is not necessarily unique.

We make use of the elementary row and column operations $P(i, k)$, $E_{i,j;\beta}$, and $E_{i,\lambda}$ described in Chapter 8, where we require the scalar λ used in $E_{i,\lambda}$ to be a unit.

Theorem 36.18. *If M is an $m \times n$ matrix over a Euclidean ring A , then there exist some invertible $n \times n$ matrix P and some invertible $m \times m$ matrix Q , where P and Q are products of elementary matrices, and a $m \times n$ matrix D of the form*

$$D = \begin{pmatrix} \alpha_1 & 0 & \cdots & 0 & 0 & \cdots & 0 \\ 0 & \alpha_2 & \cdots & 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots & \cdots & \vdots \\ 0 & 0 & \cdots & \alpha_r & 0 & \cdots & 0 \\ 0 & 0 & \cdots & 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \cdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 & 0 & \cdots & 0 \end{pmatrix}$$

for some nonzero $\alpha_i \in A$, such that

- (1) $\alpha_1 \mid \alpha_2 \mid \cdots \mid \alpha_r$, and
- (2) $M = QDP^{-1}$.

Proof. We follow Jacobson's proof [98] (Chapter 3, Theorem 3.8). We proceed by induction on $m + n$.

If $m = n = 1$, let $P = (1)$ and $Q = (1)$.

For the induction step, if $M = 0$, let $P = I_n$ and $Q = I_m$. If $M \neq 0$, the strategy is to apply a sequence of elementary transformations that converts M to a matrix of the form

$$M' = \begin{pmatrix} \alpha_1 & 0 & \cdots & 0 \\ 0 & & & \\ \vdots & & Y & \\ 0 & & & \end{pmatrix}$$

where Y is a $(m - 1) \times (n - 1)$ -matrix such that α_1 divides every entry in Y . Then, we proceed by induction on Y . To find M' , we perform the following steps.

Step 1. Pick some nonzero entry a_{ij} in M such that $\sigma(a_{ij})$ is minimal. Then permute column j and column 1, and permute row i and row 1, to bring this entry in position $(1, 1)$. We denote this new matrix again by M .

Step 2a.

If $m = 1$ go to Step 2b.

If $m > 1$, then there are two possibilities:

(i) M is of the form

$$\begin{pmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ 0 & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & a_{m2} & \cdots & a_{mn} \end{pmatrix}.$$

If $n = 1$, stop; else go to Step 2b.

(ii) There is some nonzero entry a_{i1} ($i > 1$) below a_{11} in the first column.

(a) If there is some entry a_{k1} in the first column such that a_{11} does not divide a_{k1} , then pick such an entry (say, with the smallest index i such that $\sigma(a_{i1})$ is minimal), and divide a_{k1} by a_{11} ; that is, find b_k and b_{k1} such that

$$a_{k1} = a_{11}b_k + b_{k1}, \quad \text{with } \sigma(b_{k1}) < \sigma(a_{11}).$$

Subtract b_k times row 1 from row k and permute row k and row 1, to obtain a matrix of the form

$$M = \begin{pmatrix} b_{k1} & b_{k2} & \cdots & b_{kn} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{pmatrix}.$$

Go back to Step 2a.

(b) If a_{11} divides every (nonzero) entry a_{i1} for $i \geq 2$, say $a_{i1} = a_{11}b_i$, then subtract b_i times row 1 from row i for $i = 2, \dots, m$; go to Step 2b.

Observe that whenever we return to the beginning of Step 2a, we have $\sigma(b_{k1}) < \sigma(a_{11})$. Therefore, after a finite number of steps, we must exit Step 2a with a matrix in which all entries in column 1 but the first are zero and go to Step 2b.

Step 2b.

This step is reached only if $n > 1$ and if the only nonzero entry in the first column is a_{11} .

(a) If M is of the form

$$\begin{pmatrix} a_{11} & 0 & \cdots & 0 \\ 0 & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & a_{m2} & \cdots & a_{mn} \end{pmatrix}$$

and $m = 1$ stop; else go to Step 3.

(b) If there is some entry a_{1k} in the first row such that a_{11} does not divide a_{1k} , then pick such an entry (say, with the smallest index j such that $\sigma(a_{1j})$ is minimal), and divide a_{1k} by a_{11} ; that is, find b_k and b_{1k} such that

$$a_{1k} = a_{11}b_k + b_{1k}, \quad \text{with } \sigma(b_{1k}) < \sigma(a_{11}).$$

Subtract b_k times column 1 from column k and permute column k and column 1, to obtain a matrix of the form

$$M = \begin{pmatrix} b_{1k} & a_{k2} & \cdots & a_{kn} \\ b_{2k} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ b_{mk} & a_{m2} & \cdots & a_{mn} \end{pmatrix}.$$

Go back to Step 2b.

(c) If a_{11} divides every (nonzero) entry a_{1j} for $j \geq 2$, say $a_{1j} = a_{11}b_j$, then subtract b_j times column 1 from column j for $j = 2, \dots, n$; go to Step 3.

As in Step 2a, whenever we return to the beginning of Step 2b, we have $\sigma(b_{1k}) < \sigma(a_{11})$. Therefore, after a finite number of steps, we must exit Step 2b with a matrix in which all entries in row 1 but the first are zero.

Step 3. This step is reached only if the only nonzero entry in the first row is a_{11} .

(i) If

$$M = \begin{pmatrix} a_{11} & 0 & \cdots & 0 \\ 0 & & & \\ \vdots & & Y & \\ 0 & & & \end{pmatrix}$$

go to Step 4.

(ii) If Step 2b ruined column 1 which now contains some nonzero entry below a_{11} , go back to Step 2a.

We perform a sequence of alternating steps between Step 2a and Step 2b. Because the σ -value of the $(1, 1)$ -entry strictly decreases whenever we reenter Step 2a and Step 2b, such a sequence must terminate with a matrix of the form

$$M = \begin{pmatrix} a_{11} & 0 & \cdots & 0 \\ 0 & & & \\ \vdots & & Y & \\ 0 & & & \end{pmatrix}$$

Step 4. If a_{11} divides all entries in Y , stop.

Otherwise, there is some column, say j , such that a_{11} does not divide some entry a_{ij} , so add the j th column to the first column. This yields a matrix of the form

$$M = \begin{pmatrix} a_{11} & 0 & \cdots & 0 \\ b_{2j} & & & \\ \vdots & & Y & \\ b_{mj} & & & \end{pmatrix}$$

where the i th entry in column 1 is nonzero, so go back to Step 2a,

Again, since the σ -value of the $(1, 1)$ -entry strictly decreases whenever we reenter Step 2a and Step 2b, such a sequence must terminate with a matrix of the form

$$M' = \begin{pmatrix} \alpha_1 & 0 & \cdots & 0 \\ 0 & & & \\ \vdots & & Y & \\ 0 & & & \end{pmatrix}$$

where α_1 divides every entry in Y . Then, we apply the induction hypothesis to Y . \square

If the PID A is the polynomial ring $K[X]$ where K is a field, the α_i are nonzero polynomials, so we can apply row operations to normalize their leading coefficients to be 1. We obtain the following theorem.

Theorem 36.19. (Smith Normal Form) *If M is an $m \times n$ matrix over the polynomial ring $K[X]$, where K is a field, then there exist some invertible $n \times n$ matrix P and some invertible $m \times m$ matrix Q , where P and Q are products of elementary matrices with entries in $K[X]$, and a $m \times n$ matrix D of the form*

$$D = \begin{pmatrix} q_1 & 0 & \cdots & 0 & 0 & \cdots & 0 \\ 0 & q_2 & \cdots & 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots & \cdots & \vdots \\ 0 & 0 & \cdots & q_r & 0 & \cdots & 0 \\ 0 & 0 & \cdots & 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \cdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 & 0 & \cdots & 0 \end{pmatrix}$$

for some nonzero monic polynomials $q_i \in k[X]$, such that

(1) $q_1 \mid q_2 \mid \cdots \mid q_r$, and

(2) $M = QDP^{-1}$.

In particular, if we apply Theorem 36.19 to a matrix M of the form $M = XI - A$, where A is a square matrix, then $\det(XI - A) = \chi_A(X)$ is never zero, and since $XI - A = QDP^{-1}$ with P, Q invertible, all the entries in D must be nonzero and we obtain the following result showing that the similarity invariants of A can be computed using elementary operations.

Theorem 36.20. *If A is an $n \times n$ matrix over the field K , then there exist some invertible $n \times n$ matrices P and Q , where P and Q are products of elementary matrices with entries in $K[X]$, and a $n \times n$ matrix D of the form*

$$D = \begin{pmatrix} 1 & \cdots & 0 & 0 & 0 & \cdots & 0 \\ \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & \cdots & 1 & 0 & 0 & \cdots & 0 \\ 0 & \cdots & 0 & q_1 & 0 & \cdots & 0 \\ 0 & \cdots & 0 & 0 & q_2 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & \cdots & 0 & 0 & 0 & \cdots & q_m \end{pmatrix}$$

for some nonzero monic polynomials $q_i \in k[X]$ of degree ≥ 1 , such that

- (1) $q_1 \mid q_2 \mid \cdots \mid q_m$,
- (2) q_1, \dots, q_m are the similarity invariants of A , and
- (3) $XI - A = QDP^{-1}$.

The matrix D in Theorem 36.20 is often called *Smith normal form* of A , even though this is confusing terminology since D is really the Smith normal form of $XI - A$.

Of course, we know from previous work that in Theorem 36.19, the $\alpha_1, \dots, \alpha_r$ are unique, and that in Theorem 36.20, the q_1, \dots, q_m are unique. This can also be proved using some simple properties of minors, but we leave it as an exercise (for help, look at Jacobson [98], Chapter 3, Theorem 3.9).

The rational canonical form of A can also be obtained from Q^{-1} and D , but first, let us consider the generalization of Theorem 36.19 to PID's that are not necessarily Euclidean rings.

We need to find a “norm” that assigns a natural number $\sigma(a)$ to any nonzero element of a PID A , in such a way that $\sigma(a)$ decreases whenever we return to Step 2a and Step 2b. Since a PID is a UFD, we use the number

$$\sigma(a) = k_1 + \cdots + k_r$$

of prime factors in the factorization of a nonunit element

$$a = up_1^{k_1} \cdots p_r^{k_r},$$

and we set

$$\sigma(u) = 0$$

if u is a unit.

We can't divide anymore, but we can find gcd's and use Bezout to mimic division. The key ingredient is this: for any two nonzero elements $a, b \in A$, if a does not divide b then let $d \neq 0$ be a gcd of a and b . By Bezout, there exist $x, y \in A$ such that

$$ax + by = d.$$

We can also write $a = td$ and $b = -sd$, for some $s, t \in A$, so that $tdx - sdy = d$, which implies that

$$tx - sy = 1,$$

since A is an integral domain. Observe that

$$\begin{pmatrix} t & -s \\ -y & x \end{pmatrix} \begin{pmatrix} x & s \\ y & t \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix},$$

which shows that both matrices on the left of the equation are invertible, and so is the transpose of the second one,

$$\begin{pmatrix} x & y \\ s & t \end{pmatrix}$$

(they all have determinant 1). We also have

$$as + bt = tds - sdt = 0,$$

so

$$\begin{pmatrix} x & y \\ s & t \end{pmatrix} \begin{pmatrix} a \\ b \end{pmatrix} = \begin{pmatrix} d \\ 0 \end{pmatrix}$$

and

$$(a \ b) \begin{pmatrix} x & s \\ y & t \end{pmatrix} = (d \ 0).$$

Because a does not divide b , their gcd d has strictly fewer prime factors than a , so

$$\sigma(d) < \sigma(a).$$

Using matrices of the form

$$\begin{pmatrix} x & y & 0 & 0 & \cdots & 0 \\ s & t & 0 & 0 & \cdots & 0 \\ 0 & 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 & \cdots & 1 \end{pmatrix}$$

with $xt - ys = 1$, we can modify Steps 2a and Step 2b to obtain the following theorem.

Theorem 36.21. *If M is an $m \times n$ matrix over a PID A , then there exist some invertible $n \times n$ matrix P and some invertible $m \times m$ matrix Q , where P and Q are products of elementary matrices and matrices of the form*

$$\begin{pmatrix} x & y & 0 & 0 & \cdots & 0 \\ s & t & 0 & 0 & \cdots & 0 \\ 0 & 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 & \cdots & 1 \end{pmatrix}$$

with $xt - ys = 1$, and a $m \times n$ matrix D of the form

$$D = \begin{pmatrix} \alpha_1 & 0 & \cdots & 0 & 0 & \cdots & 0 \\ 0 & \alpha_2 & \cdots & 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots & \cdots & \vdots \\ 0 & 0 & \cdots & \alpha_r & 0 & \cdots & 0 \\ 0 & 0 & \cdots & 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \cdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 & 0 & \cdots & 0 \end{pmatrix}$$

for some nonzero $\alpha_i \in A$, such that

- (1) $\alpha_1 | \alpha_2 | \cdots | \alpha_r$, and
- (2) $M = QDP^{-1}$.

Proof sketch. In Step 2a, if a_{11} does not divide a_{k1} , then first permute row 2 and row k (if $k \neq 2$). Then, if we write $a = a_{11}$ and $b = a_{k1}$, if d is a gcd of a and b and if x, y, s, t are determined as explained above, multiply on the left by the matrix

$$\begin{pmatrix} x & y & 0 & 0 & \cdots & 0 \\ s & t & 0 & 0 & \cdots & 0 \\ 0 & 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 & \cdots & 1 \end{pmatrix}$$

to obtain a matrix of the form

$$\begin{pmatrix} d & a_{12} & \cdots & a_{1n} \\ 0 & a_{22} & \cdots & a_{2n} \\ a_{31} & a_{32} & \cdots & a_{3n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{pmatrix}$$

with $\sigma(d) < \sigma(a_{11})$. Then, go back to Step 2a.

In Step 2b, if a_{11} does not divide a_{1k} , then first permute column 2 and column k (if $k \neq 2$). Then, if we write $a = a_{11}$ and $b = a_{1k}$, if d is a gcd of a and b and if x, y, s, t are determined as explained above, multiply on the right by the matrix

$$\begin{pmatrix} x & s & 0 & 0 & \cdots & 0 \\ y & t & 0 & 0 & \cdots & 0 \\ 0 & 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 & \cdots & 1 \end{pmatrix}$$

to obtain a matrix of the form

$$\begin{pmatrix} d & 0 & a_{13} & \cdots & a_{1n} \\ a_{21} & a_{22} & a_{23} & \cdots & a_{2n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & a_{m3} & \cdots & a_{mn} \end{pmatrix}$$

with $\sigma(d) < \sigma(a_{11})$. Then, go back to Step 2b. The other steps remain the same. Whenever we return to Step 2a or Step 2b, the σ -value of the $(1, 1)$ -entry strictly decreases, so the whole procedure terminates. \square

We conclude this section by explaining how the rational canonical form of a matrix A can be obtained from the canonical form QDP^{-1} of $XI - A$.

Let $f: E \rightarrow E$ be a linear map over a K -vector space of dimension n . Recall from Theorem 36.3 (see Section 36.1) that as a $K[X]$ -module, E_f is the image of the free module $E[X]$ by the map $\sigma: E[X] \rightarrow E_f$, where $E[X]$ consists of all linear combinations of the form

$$p_1e_1 + \cdots + p_ne_n,$$

where (e_1, \dots, e_n) is a basis of E and $p_1, \dots, p_n \in K[X]$ are polynomials, and σ is given by

$$\sigma(p_1e_1 + \cdots + p_ne_n) = p_1(f)(e_1) + \cdots + p_n(f)(e_n).$$

Furthermore, the kernel of σ is equal to the image of the map $\psi: E[X] \rightarrow E[X]$, where

$$\psi(p_1e_1 + \cdots + p_ne_n) = Xp_1e_1 + \cdots + Xp_ne_n - (p_1f(e_1) + \cdots + p_n(f)(e_n)).$$

The matrix A is the representation of a linear map f over the canonical basis (e_1, \dots, e_n) of $E = K^n$, and $XI - A$ is the matrix of ψ with respect to the basis (e_1, \dots, e_n)

(over $K[X]$). What Theorem 36.20 tells us is that there are $K[X]$ -bases (u_1, \dots, u_n) and (v_1, \dots, v_n) of E_f with respect to which the matrix of ψ is D . Then

$$\begin{aligned}\psi(u_i) &= v_i, \quad i = 1, \dots, n-m, \\ \psi(u_{n-m+i}) &= q_i v_{n-m+i}, \quad i = 1, \dots, m,\end{aligned}$$

and because $\text{Im}(\psi) = \text{Ker}(\sigma)$, this implies that

$$\sigma(v_i) = 0, \quad i = 1, \dots, n-m.$$

Consequently, $w_1 = \sigma(v_{n-m+1}), \dots, w_m = \sigma(v_n)$ span E_f as a $K[X]$ -module, with $w_i \in E$, and we have

$$M(f) = K[X]w_1 \oplus \cdots \oplus K[X]w_m,$$

where $K[X]w_i \approx K[X]/(q_i)$ as a cyclic $K[X]$ -module. Since $\text{Im}(\psi) = \text{Ker}(\sigma)$, we have

$$0 = \sigma(\psi(u_{n-m+i})) = \sigma(q_i v_{n-m+i}) = q_i \sigma(v_{n-m+i}) = q_i w_i,$$

so as a K -vector space, the cyclic subspace $Z(w_i; f) = K[X]w_i$ has q_i as annihilator, and by a remark from Section 36.1, it has the basis (over K)

$$(w_i, f(w_i), \dots, f^{n_i-1}(w_i)), \quad n_i = \deg(q_i).$$

Furthermore, over this basis, the restriction of f to $Z(w_i; f)$ is represented by the companion matrix of q_i . By putting all these bases together, we obtain a block matrix which is the canonical rational form of f (and A).

Now, $XI - A = QDP^{-1}$ is the matrix of ψ with respect to the canonical basis (e_1, \dots, e_n) (over $K[X]$), and D is the matrix of ψ with respect to the bases (u_1, \dots, u_n) and (v_1, \dots, v_n) (over $K[X]$), which tells us that the columns of Q consist of the coordinates (in $K[X]$) of the basis vectors (v_1, \dots, v_n) with respect to the basis (e_1, \dots, e_n) . Therefore, the coordinates (in K) of the vectors (w_1, \dots, w_m) spanning E_f over $K[X]$, where $w_i = \sigma(v_{n-m+i})$, are obtained by substituting the matrix A for X in the coordinates of the columns vectors of Q , and evaluating the resulting expressions.

Since

$$D = Q^{-1}(XI - A)P,$$

the matrix D is obtained from A by a sequence of elementary row operations whose product is Q^{-1} and a sequence of elementary column operations whose product is P . Therefore, to compute the vectors w_1, \dots, w_m from A , we simply have to figure out how to construct Q from the sequence of elementary row operations that yield Q^{-1} . The trick is to use column operations to gather a product of row operations in reverse order.

Indeed, if Q^{-1} is the product of elementary row operations

$$Q^{-1} = E_k \cdots E_2 E_1,$$

then

$$Q = E_1^{-1} E_2^{-1} \cdots E_k^{-1}.$$

Now, row operations operate on the left and column operations operate on the right, so the product $E_1^{-1} E_2^{-1} \cdots E_k^{-1}$ can be computed from left to right as a sequence of column operations.

Let us review the meaning of the elementary row and column operations $P(i, k)$, $E_{i,j;\beta}$, and $E_{i,\lambda}$.

1. As a row operation, $P(i, k)$ permutes row i and row k .
2. As a column operation, $P(i, k)$ permutes column i and column k .
3. The inverse of $P(i, k)$ is $P(i, k)$ itself.
4. As a row operation, $E_{i,j;\beta}$ adds β times row j to row i .
5. As a column operation, $E_{i,j;\beta}$ adds β times column i to column j (note the switch in the indices).
6. The inverse of $E_{i,j;\beta}$ is $E_{i,j;-\beta}$.
7. As a row operation, $E_{i,\lambda}$ multiplies row i by λ .
8. As a column operation, $E_{i,\lambda}$ multiplies column i by λ .
9. The inverse of $E_{i,\lambda}$ is $E_{i,\lambda^{-1}}$.

Given a square matrix A (over K), the row and column operations applied to $XI - A$ in converting it to its Smith normal form may involve coefficients that are polynomials and it is necessary to explain what is the action of an operation $E_{i,j;\beta}$ in this case. If the coefficient β in $E_{i,j;\beta}$ is a polynomial over K , as a row operation, the action of $E_{i,j;\beta}$ on a matrix X is to multiply the j th row of M by the matrix $\beta(A)$ obtained by substituting the matrix A for X and then to add the resulting vector to row i . Similarly, as a column operation, the action of $E_{i,j;\beta}$ on a matrix X is to multiply the i th column of M by the matrix $\beta(A)$ obtained by substituting the matrix A for X and then to add the resulting vector to column j . An algorithm to compute the rational canonical form of a matrix can now be given. We apply the elementary column operations E_i^{-1} for $i = 1, \dots, k$, starting with the identity matrix.

Algorithm for Converting an $n \times n$ matrix to Rational Canonical Form

While applying elementary row and column operations to compute the Smith normal form D of $XI - A$, keep track of the row operations and perform the following steps:

1. Let $P' = I_n$, and for every elementary row operation E do the following:
 - (a) If $E = P(i, k)$, permute column i and column k of P' .

- (b) If $E = E_{i,j;\beta}$, multiply the i th column of P' by the matrix $\beta(A)$ obtained by substituting the matrix A for X , and then subtract the resulting vector from column j .
- (c) If $E = E_{i,\lambda}$ where $\lambda \in K$, then multiply the i th column of P' by λ^{-1} .
2. When step (1) terminates, the first $n - m$ columns of P' are zero and the last m are linearly independent. For $i = 1, \dots, m$, multiply the $(n - m + i)$ th column w_i of P' successively by I, A^1, A^2, A^{n_i-1} , where n_i is the degree of the polynomial q_i (appearing in D), and form the $n \times n$ matrix P consisting of the vectors

$$w_1, Aw_1, \dots, A^{n_1-1}w_1, w_2, Aw_2, \dots, A^{n_2-1}w_2, \dots, w_m, Aw_m, \dots, A^{n_m-1}w_m.$$

Then, $P^{-1}AP$ is the canonical rational form of A .

Here is an example taken from Dummit and Foote [54] (Chapter 12, Section 12.2). Let A be the matrix

$$A = \begin{pmatrix} 1 & 2 & -4 & 4 \\ 2 & -1 & 4 & -8 \\ 1 & 0 & 1 & -2 \\ 0 & 1 & -2 & 3 \end{pmatrix}.$$

One should check that the following sequence of row and column operations produces the Smith normal form D of $XI - A$:

$$\begin{array}{cccccc} \text{row } P(1,3) & \text{row } E_{1,-1} & \text{row } E_{2,1;2} & \text{row } E_{3,1;-(X-1)} & \text{column } E_{1,3;X-1} & \text{column } E_{1,4;2} \\ \text{row } P(2,4) & \text{row } E_{2,-1} & \text{row } E_{3,2;2} & \text{row } E_{4,2;-(X+1)} & \text{column } E_{2,3;2} & \text{column } E_{2,4;X-3}, \end{array}$$

with

$$D = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & (X-1)^2 & 0 \\ 0 & 0 & 0 & (X-1)^2 \end{pmatrix}.$$

Then, applying Step 1 of the above algorithm, we get the sequence of column operations:

$$\begin{array}{ccccccc} \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} & \xrightarrow{P(1,3)} & \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} & \xrightarrow{E_{1,-1}} & \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} & \xrightarrow{E_{2,1,-2}} \\ \begin{pmatrix} 0 & 0 & 1 & 0 \\ -2 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} & \xrightarrow{E_{3,1,A-I}} & \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} & \xrightarrow{P(2,4)} & \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix} & \xrightarrow{E_{2,-1}} \\ \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{pmatrix} & \xrightarrow{E_{3,2,-2}} & \begin{pmatrix} 0 & -2 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{pmatrix} & \xrightarrow{E_{4,2;A+I}} & \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} & = P'. \end{array}$$

Step 2 of the algorithm yields the vectors

$$\begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \end{pmatrix}, \quad A \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} 1 \\ 2 \\ 1 \\ 0 \end{pmatrix}, \quad \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \end{pmatrix}, \quad A \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} 2 \\ -1 \\ 0 \\ 1 \end{pmatrix},$$

so we get

$$P = \begin{pmatrix} 1 & 1 & 0 & 2 \\ 0 & 2 & 1 & -1 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}.$$

We find that

$$P^{-1} = \begin{pmatrix} 1 & 0 & -1 & -2 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & -2 & 1 \\ 0 & 0 & 0 & 1 \end{pmatrix},$$

and thus, the rational canonical form of A is

$$P^{-1}AP = \begin{pmatrix} 0 & -1 & 0 & 0 \\ 1 & 2 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 2 \end{pmatrix}.$$

Topology, Differential Calculus

Chapter 37

Topology

37.1 Metric Spaces and Normed Vector Spaces

This chapter contains a review of basic topological concepts. First metric spaces are defined. Next normed vector spaces are defined. Closed and open sets are defined, and their basic properties are stated. The general concept of a topological space is defined. The closure and the interior of a subset are defined. The subspace topology and the product topology are defined. Continuous maps and homeomorphisms are defined. Limits of sequences are defined. Continuous linear maps and multilinear maps are defined and studied briefly. The chapter ends with the definition of a normed affine space.

Most spaces considered in this book have a topological structure given by a metric or a norm, and we first review these notions. We begin with metric spaces. Recall that $\mathbb{R}_+ = \{x \in \mathbb{R} \mid x \geq 0\}$.

Definition 37.1. A *metric space* is a set E together with a function $d: E \times E \rightarrow \mathbb{R}_+$, called a *metric, or distance*, assigning a nonnegative real number $d(x, y)$ to any two points $x, y \in E$, and satisfying the following conditions for all $x, y, z \in E$:

$$(D1) \quad d(x, y) = d(y, x). \quad (\text{symmetry})$$

$$(D2) \quad d(x, y) \geq 0, \text{ and } d(x, y) = 0 \text{ iff } x = y. \quad (\text{positivity})$$

$$(D3) \quad d(x, z) \leq d(x, y) + d(y, z). \quad (\text{triangle inequality})$$

Geometrically, Condition (D3) expresses the fact that in a triangle with vertices x, y, z , the length of any side is bounded by the sum of the lengths of the other two sides. From (D3), we immediately get

$$|d(x, y) - d(y, z)| \leq d(x, z).$$

Let us give some examples of metric spaces. Recall that the *absolute value* $|x|$ of a real number $x \in \mathbb{R}$ is defined such that $|x| = x$ if $x \geq 0$, $|x| = -x$ if $x < 0$, and for a complex number $x = a + ib$, by $|x| = \sqrt{a^2 + b^2}$.

Example 37.1.

1. Let $E = \mathbb{R}$, and $d(x, y) = |x - y|$, the absolute value of $x - y$. This is the so-called natural metric on \mathbb{R} .
2. Let $E = \mathbb{R}^n$ (or $E = \mathbb{C}^n$). We have the *Euclidean metric*

$$d_2(x, y) = \left(|x_1 - y_1|^2 + \cdots + |x_n - y_n|^2 \right)^{\frac{1}{2}},$$

the distance between the points (x_1, \dots, x_n) and (y_1, \dots, y_n) .

3. For every set E , we can define the *discrete metric*, defined such that $d(x, y) = 1$ iff $x \neq y$, and $d(x, x) = 0$.
4. For any $a, b \in \mathbb{R}$ such that $a < b$, we define the following sets:

$$[a, b] = \{x \in \mathbb{R} \mid a \leq x \leq b\}, \quad (\text{closed interval})$$

$$(a, b) = \{x \in \mathbb{R} \mid a < x < b\}, \quad (\text{open interval})$$

$$[a, b) = \{x \in \mathbb{R} \mid a \leq x < b\}, \quad (\text{interval closed on the left, open on the right})$$

$$(a, b] = \{x \in \mathbb{R} \mid a < x \leq b\}, \quad (\text{interval open on the left, closed on the right})$$

Let $E = [a, b]$, and $d(x, y) = |x - y|$. Then, $([a, b], d)$ is a metric space.

We will need to define the notion of proximity in order to define convergence of limits and continuity of functions. For this we introduce some standard “small neighborhoods.”

Definition 37.2. Given a metric space E with metric d , for every $a \in E$, for every $\rho \in \mathbb{R}$, with $\rho > 0$, the set

$$B(a, \rho) = \{x \in E \mid d(a, x) \leq \rho\}$$

is called the *closed ball of center a and radius ρ*, the set

$$B_0(a, \rho) = \{x \in E \mid d(a, x) < \rho\}$$

is called the *open ball of center a and radius ρ*, and the set

$$S(a, \rho) = \{x \in E \mid d(a, x) = \rho\}$$

is called the *sphere of center a and radius ρ*. It should be noted that ρ is finite (i.e., not $+\infty$). A subset X of a metric space E is *bounded* if there is a closed ball $B(a, \rho)$ such that $X \subseteq B(a, \rho)$.

Clearly, $B(a, \rho) = B_0(a, \rho) \cup S(a, \rho)$.

Example 37.2.

1. In $E = \mathbb{R}$ with the distance $|x - y|$, an open ball of center a and radius ρ is the open interval $(a - \rho, a + \rho)$.
2. In $E = \mathbb{R}^2$ with the Euclidean metric, an open ball of center a and radius ρ is the set of points inside the disk of center a and radius ρ , excluding the boundary points on the circle.
3. In $E = \mathbb{R}^3$ with the Euclidean metric, an open ball of center a and radius ρ is the set of points inside the sphere of center a and radius ρ , excluding the boundary points on the sphere.

One should be aware that intuition can be misleading in forming a geometric image of a closed (or open) ball. For example, if d is the discrete metric, a closed ball of center a and radius $\rho < 1$ consists only of its center a , and a closed ball of center a and radius $\rho \geq 1$ consists of the entire space!

If $E = [a, b]$, and $d(x, y) = |x - y|$, as in Example 37.1, an open ball $B_0(a, \rho)$, with $\rho < b - a$, is in fact the interval $[a, a + \rho]$, which is closed on the left.

We now consider a very important special case of metric spaces, normed vector spaces. Normed vector spaces have already been defined in Chapter 9 (Definition 9.1) but for the reader's convenience we repeat the definition.

Definition 37.3. Let E be a vector space over a field K , where K is either the field \mathbb{R} of reals, or the field \mathbb{C} of complex numbers. A *norm on E* is a function $\| \| : E \rightarrow \mathbb{R}_+$, assigning a nonnegative real number $\|u\|$ to any vector $u \in E$, and satisfying the following conditions for all $x, y, z \in E$:

$$(N1) \quad \|x\| \geq 0, \text{ and } \|x\| = 0 \text{ iff } x = 0. \quad (\text{positivity})$$

$$(N2) \quad \|\lambda x\| = |\lambda| \|x\|. \quad (\text{scaling})$$

$$(N3) \quad \|x + y\| \leq \|x\| + \|y\|. \quad (\text{triangle inequality})$$

A vector space E together with a norm $\| \|$ is called a *normed vector space*.

From (N3), we easily get

$$\| \|x\| - \|y\|\| \leq \|x - y\|.$$

Given a normed vector space E , if we define d such that

$$d(x, y) = \|x - y\|,$$

it is easily seen that d is a metric. Thus, every normed vector space is immediately a metric space. Note that the metric associated with a norm is invariant under translation, that is,

$$d(x + u, y + u) = d(x, y).$$

For this reason, we can restrict ourselves to open or closed balls of center 0.

Examples of normed vector spaces were given in Example 9.1. We repeat the most important examples.

Example 37.3. Let $E = \mathbb{R}^n$ (or $E = \mathbb{C}^n$). There are three standard norms. For every $(x_1, \dots, x_n) \in E$, we have the norm $\|x\|_1$, defined such that,

$$\|x\|_1 = |x_1| + \cdots + |x_n|,$$

we have the *Euclidean norm* $\|x\|_2$, defined such that,

$$\|x\|_2 = \left(|x_1|^2 + \cdots + |x_n|^2 \right)^{\frac{1}{2}},$$

and the *sup-norm* $\|x\|_\infty$, defined such that,

$$\|x\|_\infty = \max\{|x_i| \mid 1 \leq i \leq n\}.$$

More generally, we define the ℓ_p -norm (for $p \geq 1$) by

$$\|x\|_p = \left(|x_1|^p + \cdots + |x_n|^p \right)^{1/p}.$$

We proved in Proposition 9.1 that the ℓ_p -norms are indeed norms. The closed unit balls centered at $(0, 0)$ for $\|\cdot\|_1$, $\|\cdot\|_2$, and $\|\cdot\|_\infty$, along with the containment relationships, are shown in Figures 37.1 and 37.2. Figures 37.3 and 37.4 illustrate the situation in \mathbb{R}^3 .

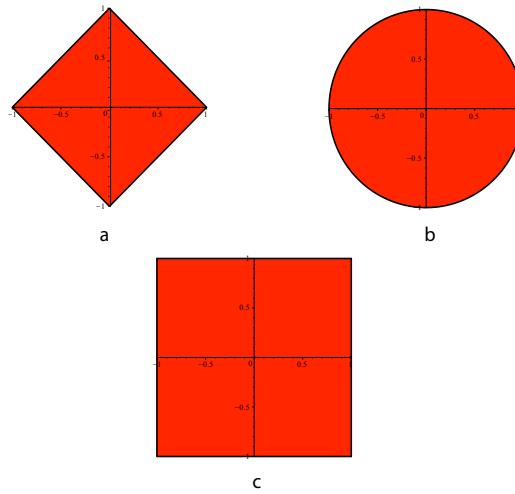

Figure 37.1: Figure (a) shows the diamond shaped closed ball associated with $\|\cdot\|_1$. Figure (b) shows the closed unit disk associated with $\|\cdot\|_2$, while Figure (c) illustrates the closed unit ball associated with $\|\cdot\|_\infty$.

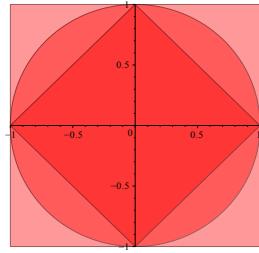

Figure 37.2: The relationship between the closed unit balls centered at $(0, 0)$.

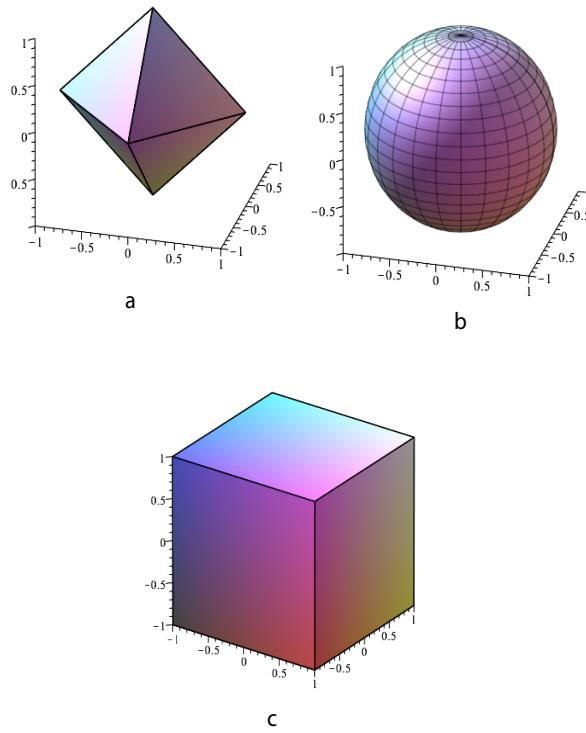

Figure 37.3: Figure (a) shows the octahedral shaped closed ball associated with $\|\cdot\|_1$. Figure (b) shows the closed spherical associated with $\|\cdot\|_2$, while Figure (c) illustrates the closed unit ball associated with $\|\cdot\|_\infty$.

In a normed vector space we define a closed ball or an open ball of radius ρ as a closed ball or an open ball of center 0. We may use the notation $B(\rho)$ and $B_0(\rho)$.

We will now define the crucial notions of open sets and closed sets, and of a topological space.

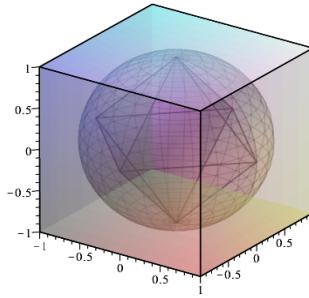

Figure 37.4: The relationship between the closed unit balls centered at $(0, 0, 0)$.

Definition 37.4. Let (E, d) be a metric space. A subset $U \subseteq E$ is an *open set* in E if either $U = \emptyset$, or for every $a \in U$, there is some open ball $B_0(a, \rho)$ such that, $B_0(a, \rho) \subseteq U$.¹ A subset $F \subseteq E$ is a *closed set* in E if its complement $E - F$ is open in E . See Figure 37.5.

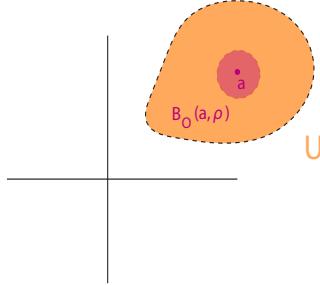

Figure 37.5: An open set U in $E = \mathbb{R}^2$ under the standard Euclidean metric. Any point in the peach set U is surrounded by a small raspberry open set which lies within U .

The set E itself is open, since for every $a \in E$, every open ball of center a is contained in E . In $E = \mathbb{R}^n$, given n intervals $[a_i, b_i]$, with $a_i < b_i$, it is easy to show that the open n -cube

$$\{(x_1, \dots, x_n) \in E \mid a_i < x_i < b_i, 1 \leq i \leq n\}$$

is an open set. In fact, it is possible to find a metric for which such open n -cubes are open balls! Similarly, we can define the closed n -cube

$$\{(x_1, \dots, x_n) \in E \mid a_i \leq x_i \leq b_i, 1 \leq i \leq n\},$$

which is a closed set.

The open sets satisfy some important properties that lead to the definition of a topological space.

¹Recall that $\rho > 0$.

Proposition 37.1. *Given a metric space E with metric d , the family \mathcal{O} of all open sets defined in Definition 37.4 satisfies the following properties:*

- (O1) *For every finite family $(U_i)_{1 \leq i \leq n}$ of sets $U_i \in \mathcal{O}$, we have $U_1 \cap \dots \cap U_n \in \mathcal{O}$, i.e., \mathcal{O} is closed under finite intersections.*
- (O2) *For every arbitrary family $(U_i)_{i \in I}$ of sets $U_i \in \mathcal{O}$, we have $\bigcup_{i \in I} U_i \in \mathcal{O}$, i.e., \mathcal{O} is closed under arbitrary unions.*
- (O3) $\emptyset \in \mathcal{O}$, and $E \in \mathcal{O}$, i.e., \emptyset and E belong to \mathcal{O} .

Furthermore, for any two distinct points $a \neq b$ in E , there exist two open sets U_a and U_b such that, $a \in U_a$, $b \in U_b$, and $U_a \cap U_b = \emptyset$.

Proof. It is straightforward. For the last point, letting $\rho = d(a, b)/3$ (in fact $\rho = d(a, b)/2$ works too), we can pick $U_a = B_0(a, \rho)$ and $U_b = B_0(b, \rho)$. By the triangle inequality, we must have $U_a \cap U_b = \emptyset$. \square

The above proposition leads to the very general concept of a topological space.

One should be careful that, in general, the family of open sets is not closed under infinite intersections. For example, in \mathbb{R} under the metric $|x - y|$, letting $U_n = (-1/n, +1/n)$, each U_n is open, but $\bigcap_n U_n = \{0\}$, which is not open.

Later on, given any nonempty subset A of a metric space (E, d) , we will need to know that certain special sets containing A are open.

Definition 37.5. Let (E, d) be a metric space. For any nonempty subset A of E and any $x \in E$, let

$$d(x, A) = \inf_{a \in A} d(x, a).$$

Proposition 37.2. *Let (E, d) be a metric space. For any nonempty subset A of E and for any two points $x, y \in E$, we have*

$$|d(x, A) - d(y, A)| \leq d(x, y).$$

Proof. For all $a \in A$ we have

$$d(x, a) \leq d(x, y) + d(y, a),$$

which implies

$$\begin{aligned} d(x, A) &= \inf_{a \in A} d(x, a) \\ &\leq \inf_{a \in A} (d(x, y) + d(y, a)) \\ &= d(x, y) + \inf_{a \in A} d(y, a) \\ &= d(x, y) + d(y, A). \end{aligned}$$

By symmetry, we also obtain $d(y, A) \leq d(x, y) + d(x, A)$, and thus

$$|d(x, A) - d(y, A)| \leq d(x, y),$$

as claimed. \square

Definition 37.6. Let (E, d) be a metric space. For any nonempty subset A of E , and any $r > 0$, let

$$V_r(A) = \{x \in E \mid d(x, A) < r\}.$$

Proposition 37.3. Let (E, d) be a metric space. For any nonempty subset A of E , and any $r > 0$, the set $V_r(A)$ is an open set containing A .

Proof. For any $y \in E$ such that $d(x, y) < r - d(x, A)$, by Proposition 37.2 we have

$$d(y, A) \leq d(x, A) + d(x, y) \leq d(x, A) + r - d(x, A) = r,$$

so $V_r(A)$ contains the open ball $B_0(x, r - d(x, A))$, which means that it is open. Obviously, $A \subseteq V_r(A)$. \square

37.2 Topological Spaces

Motivated by Proposition 37.1, a topological space is defined in terms of a family of sets satisfying the properties of open sets stated in that proposition.

Definition 37.7. Given a set E , a *topology on E (or a topological structure on E)*, is defined as a family \mathcal{O} of subsets of E called *open sets*, and satisfying the following three properties:

- (1) For every finite family $(U_i)_{1 \leq i \leq n}$ of sets $U_i \in \mathcal{O}$, we have $U_1 \cap \cdots \cap U_n \in \mathcal{O}$, i.e., \mathcal{O} is closed under finite intersections.
- (2) For every arbitrary family $(U_i)_{i \in I}$ of sets $U_i \in \mathcal{O}$, we have $\bigcup_{i \in I} U_i \in \mathcal{O}$, i.e., \mathcal{O} is closed under arbitrary unions.
- (3) $\emptyset \in \mathcal{O}$, and $E \in \mathcal{O}$, i.e., \emptyset and E belong to \mathcal{O} .

A set E together with a topology \mathcal{O} on E is called a *topological space*. Given a topological space (E, \mathcal{O}) , a subset F of E is a *closed set* if $F = E - U$ for some open set $U \in \mathcal{O}$, i.e., F is the complement of some open set.

It is possible that an open set is also a closed set. For example, \emptyset and E are both open and closed. When a topological space contains a proper nonempty subset U which is both open and closed, the space E is said to be *disconnected*.

Definition 37.8. A topological space (E, \mathcal{O}) is said to satisfy the *Hausdorff separation axiom* (or T_2 -separation axiom) if for any two distinct points $a \neq b$ in E , there exist two open sets U_a and U_b such that, $a \in U_a$, $b \in U_b$, and $U_a \cap U_b = \emptyset$. When the T_2 -separation axiom is satisfied, we also say that (E, \mathcal{O}) is a *Hausdorff space*.

As shown by Proposition 37.1, any metric space is a topological Hausdorff space, the family of open sets being in fact the family of arbitrary unions of open balls. Similarly, any normed vector space is a topological Hausdorff space, the family of open sets being the family of arbitrary unions of open balls. The topology \mathcal{O} consisting of all subsets of E is called the *discrete topology*.

Remark: Most (if not all) spaces used in analysis are Hausdorff spaces. Intuitively, the Hausdorff separation axiom says that there are enough “small” open sets. Without this axiom, some counter-intuitive behaviors may arise. For example, a sequence may have more than one limit point (or a compact set may not be closed). Nevertheless, non-Hausdorff topological spaces arise naturally in algebraic geometry. But even there, some substitute for separation is used.

One of the reasons why topological spaces are important is that the definition of a topology only involves a certain family \mathcal{O} of sets, and not **how** such family is generated from a metric or a norm. For example, different metrics or different norms can define the same family of open sets. Many topological properties only depend on the family \mathcal{O} and not on the specific metric or norm. But the fact that a topology is definable from a metric or a norm is important, because it usually implies nice properties of a space. All our examples will be spaces whose topology is defined by a metric or a norm.

Definition 37.9. A topological space (E, \mathcal{O}) is *metrizable* if there is a distance on E defining the topology \mathcal{O} .

Note that in a metric space (E, d) , the metric d is *explicitly given*. However, in general, the topology of a metrizable space (E, \mathcal{O}) is not specified by an explicitly given metric, but *some metric* defining the topology \mathcal{O} exists. Obviously, a metrizable topological space must be Hausdorff. Actually, a stronger separation property holds, a metrizable space is normal; see Definition 37.30.

Remark: By taking complements we can state properties of the closed sets dual to those of Definition 37.7. Thus, \emptyset and E are closed sets, and the closed sets are closed under finite unions and arbitrary intersections.

It is also worth noting that the Hausdorff separation axiom implies that for every $a \in E$, the set $\{a\}$ is closed. Indeed, if $x \in E - \{a\}$, then $x \neq a$, and so there exist open sets U_a and U_x such that $a \in U_a$, $x \in U_x$, and $U_a \cap U_x = \emptyset$. See Figure 37.6. Thus, for every $x \in E - \{a\}$, there is an open set U_x containing x and contained in $E - \{a\}$, showing by (O3) that $E - \{a\}$ is open, and thus that the set $\{a\}$ is closed.

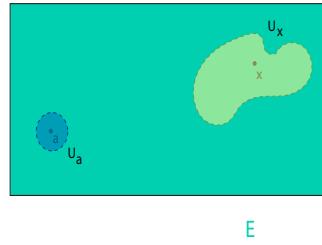

Figure 37.6: A schematic illustration of the Hausdorff separation property

Given a topological space (E, \mathcal{O}) , given any subset A of E , since $E \in \mathcal{O}$ and E is a closed set, the family $\mathcal{C}_A = \{F \mid A \subseteq F, F \text{ a closed set}\}$ of closed sets containing A is nonempty, and since any arbitrary intersection of closed sets is a closed set, the intersection $\bigcap \mathcal{C}_A$ of the sets in the family \mathcal{C}_A is the smallest closed set containing A . By a similar reasoning, the union of all the open subsets contained in A is the largest open set contained in A .

Definition 37.10. Given a topological space (E, \mathcal{O}) , given any subset A of E , the smallest closed set containing A is denoted by \overline{A} , and is called the *closure, or adherence* of A . See Figure 37.7. A subset A of E is *dense in E* if $\overline{A} = E$. The largest open set contained in A is denoted by $\overset{\circ}{A}$, and is called the *interior of A* . See Figure 37.8. The set $\text{Fr } A = \overline{A} \cap \overline{E - A}$ is called the *boundary (or frontier) of A* . We also denote the boundary of A by ∂A . See Figure 37.9.

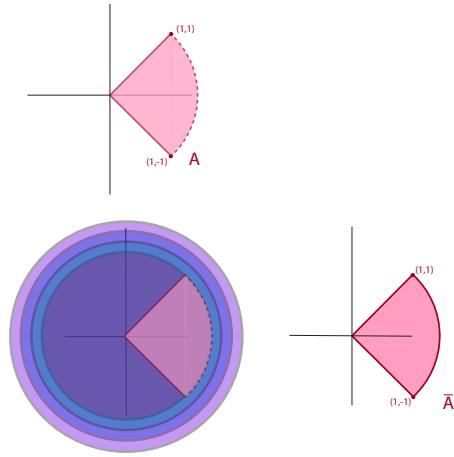

Figure 37.7: The topological space (E, \mathcal{O}) is \mathbb{R}^2 with topology induced by the Euclidean metric. The subset A is the section $B_0(1)$ in the first and fourth quadrants bound by the lines $y = x$ and $y = -x$. The closure of A is obtained by the intersection of A with the closed unit ball.

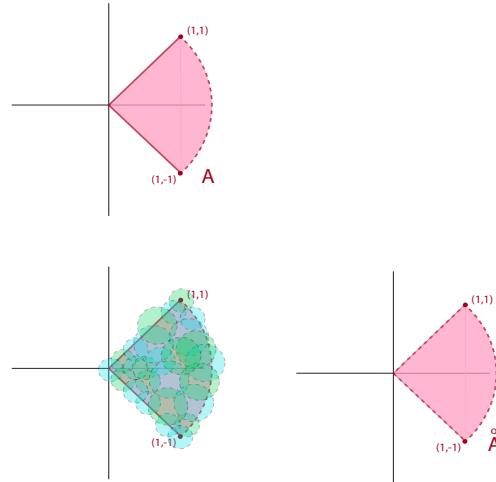

Figure 37.8: The topological space (E, \mathcal{O}) is \mathbb{R}^2 with topology induced by the Euclidean metric. The subset A is the section $B_0(1)$ in the first and fourth quadrants bound by the lines $y = x$ and $y = -x$. The interior of A is obtained by the covering A with small open balls.

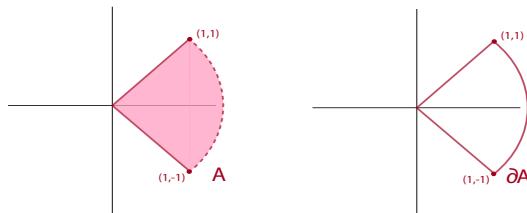

Figure 37.9: The topological space (E, \mathcal{O}) is \mathbb{R}^2 with topology induced by the Euclidean metric. The subset A is the section $B_0(1)$ in the first and fourth quadrants bound by the lines $y = x$ and $y = -x$. The boundary of A is $\overline{A} - \overset{\circ}{A}$.

Remark: The notation \overline{A} for the closure of a subset A of E is somewhat unfortunate, since \overline{A} is often used to denote the set complement of A in E . Still, we prefer it to more cumbersome notations such as $\text{clo}(A)$, and we denote the complement of A in E by $E - A$ (or sometimes, A^c).

By definition, it is clear that a subset A of E is closed iff $A = \overline{A}$. The set \mathbb{Q} of rationals is dense in \mathbb{R} . It is easily shown that $\overline{A} = \overset{\circ}{A} \cup \partial A$ and $\overset{\circ}{A} \cap \partial A = \emptyset$. Another useful characterization of \overline{A} is given by the following proposition.

Proposition 37.4. *Given a topological space (E, \mathcal{O}) , given any subset A of E , the closure \overline{A} of A is the set of all points $x \in E$ such that for every open set U containing x , then $U \cap A \neq \emptyset$. See Figure 37.10.*

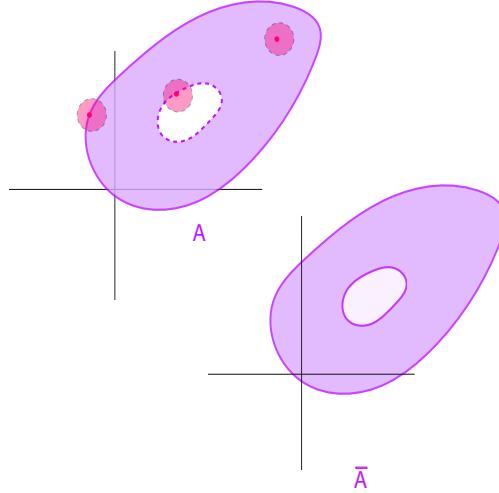

Figure 37.10: The topological space (E, \mathcal{O}) is \mathbb{R}^2 with topology induced by the Euclidean metric. The purple subset A is illustrated with three red points, each in its closure since the open ball centered at each point has nontrivial intersection with A .

Proof. If $A = \emptyset$, since \emptyset is closed, the proposition holds trivially. Thus, assume that $A \neq \emptyset$. First assume that $x \in \overline{A}$. Let U be any open set such that $x \in U$. If $U \cap A = \emptyset$, since U is open, then $E - U$ is a closed set containing A , and since \overline{A} is the intersection of all closed sets containing A , we must have $x \in E - U$, which is impossible. Conversely, assume that $x \in E$ is a point such that for every open set U containing x , then $U \cap A \neq \emptyset$. Let F be any closed subset containing A . If $x \notin F$, since F is closed, then $U = E - F$ is an open set such that $x \in U$, and $U \cap A = \emptyset$, a contradiction. Thus, we have $x \in F$ for every closed set containing A , that is, $x \in \overline{A}$. \square

Often it is necessary to consider a subset A of a topological space E , and to view the subset A as a topological space. The following proposition shows how to define a topology on a subset.

Proposition 37.5. *Given a topological space (E, \mathcal{O}) , given any subset A of E , let*

$$\mathcal{U} = \{U \cap A \mid U \in \mathcal{O}\}$$

be the family of all subsets of A obtained as the intersection of any open set in \mathcal{O} with A . The following properties hold.

- (1) The space (A, \mathcal{U}) is a topological space.
- (2) If E is a metric space with metric d , then the restriction $d_A: A \times A \rightarrow \mathbb{R}_+$ of the metric d to A defines a metric space. Furthermore, the topology induced by the metric d_A agrees with the topology defined by \mathcal{U} , as above.

Proof. Left as an exercise. □

Proposition 37.5 suggests the following definition.

Definition 37.11. Given a topological space (E, \mathcal{O}) , given any subset A of E , the *subspace topology on A induced by \mathcal{O}* is the family \mathcal{U} of open sets defined such that

$$\mathcal{U} = \{U \cap A \mid U \in \mathcal{O}\}$$

is the family of all subsets of A obtained as the intersection of any open set in \mathcal{O} with A . We say that (A, \mathcal{U}) has the *subspace topology*. If (E, d) is a metric space, the restriction $d_A: A \times A \rightarrow \mathbb{R}_+$ of the metric d to A is called the *subspace metric*.

For example, if $E = \mathbb{R}^n$ and d is the Euclidean metric, we obtain the subspace topology on the closed n -cube

$$\{(x_1, \dots, x_n) \in E \mid a_i \leq x_i \leq b_i, 1 \leq i \leq n\}.$$

See Figure 37.11,

One should realize that every open set $U \in \mathcal{O}$ which is entirely contained in A is also in the family \mathcal{U} , but \mathcal{U} may contain open sets that are not in \mathcal{O} . For example, if $E = \mathbb{R}$ with $|x - y|$, and $A = [a, b]$, then sets of the form $[a, c)$, with $a < c < b$ belong to \mathcal{U} , but they are not open sets for \mathbb{R} under $|x - y|$. However, there is agreement in the following situation.

Proposition 37.6. Given a topological space (E, \mathcal{O}) , given any subset A of E , if \mathcal{U} is the subspace topology, then the following properties hold.

- (1) If A is an open set $A \in \mathcal{O}$, then every open set $U \in \mathcal{U}$ is an open set $U \in \mathcal{O}$.
- (2) If A is a closed set in E , then every closed set w.r.t. the subspace topology is a closed set w.r.t. \mathcal{O} .

Proof. Left as an exercise. □

The concept of product topology is also useful. We have the following proposition.

Proposition 37.7. Given n topological spaces (E_i, \mathcal{O}_i) , let \mathcal{B} be the family of subsets of $E_1 \times \dots \times E_n$ defined as follows:

$$\mathcal{B} = \{U_1 \times \dots \times U_n \mid U_i \in \mathcal{O}_i, 1 \leq i \leq n\},$$

and let \mathcal{P} be the family consisting of arbitrary unions of sets in \mathcal{B} , including \emptyset . Then \mathcal{P} is a topology on $E_1 \times \dots \times E_n$.

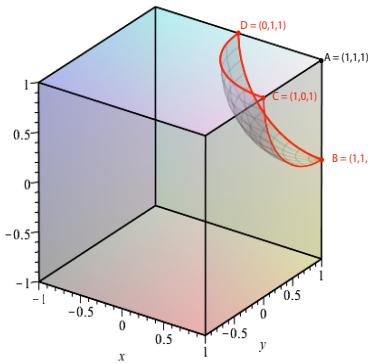

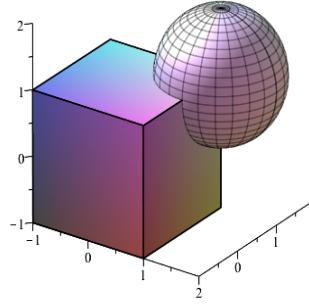

Figure 37.11: An example of an open set in the subspace topology for $\{(x, y, z) \in \mathbb{R}^3 \mid -1 \leq x \leq 1, -1 \leq y \leq 1, -1 \leq z \leq 1\}$. The open set is the corner region $ABCD$ and is obtained by intersecting the cube $B_0((1, 1, 1), 1)$.

Proof. Left as an exercise. □

Definition 37.12. Given n topological spaces (E_i, \mathcal{O}_i) , the *product topology* on $E_1 \times \cdots \times E_n$ is the family \mathcal{P} of subsets of $E_1 \times \cdots \times E_n$ defined as follows: if

$$\mathcal{B} = \{U_1 \times \cdots \times U_n \mid U_i \in \mathcal{O}_i, 1 \leq i \leq n\},$$

then \mathcal{P} is the family consisting of arbitrary unions of sets in \mathcal{B} , including \emptyset . See Figure 37.12.

If each (E_i, d_{E_i}) is a metric space, there are three natural metrics that can be defined on $E_1 \times \cdots \times E_n$:

$$\begin{aligned} d_1((x_1, \dots, x_n), (y_1, \dots, y_n)) &= d_{E_1}(x_1, y_1) + \cdots + d_{E_n}(x_n, y_n), \\ d_2((x_1, \dots, x_n), (y_1, \dots, y_n)) &= ((d_{E_1}(x_1, y_1))^2 + \cdots + (d_{E_n}(x_n, y_n))^2)^{\frac{1}{2}}, \\ d_\infty((x_1, \dots, x_n), (y_1, \dots, y_n)) &= \max\{d_{E_1}(x_1, y_1), \dots, d_{E_n}(x_n, y_n)\}. \end{aligned}$$

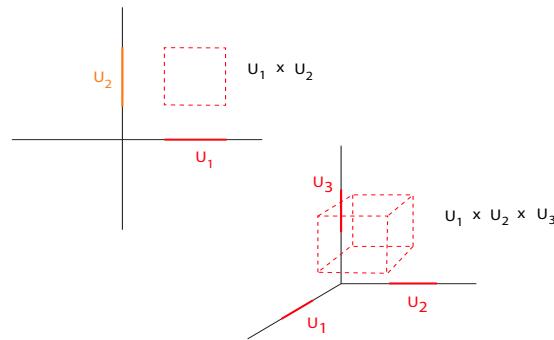

Figure 37.12: Examples of open sets in the product topology for \mathbb{R}^2 and \mathbb{R}^3 induced by the Euclidean metric.

It is easy to show that

$$\begin{aligned} d_\infty((x_1, \dots, x_n), (y_1, \dots, y_n)) &\leq d_2((x_1, \dots, x_n), (y_1, \dots, y_n)) \leq d_1((x_1, \dots, x_n), (y_1, \dots, y_n)) \\ &\leq nd_\infty((x_1, \dots, x_n), (y_1, \dots, y_n)), \end{aligned}$$

so these distances define the same topology, which is the product topology.

If each $(E_i, \|\cdot\|_{E_i})$ is a normed vector space, there are three natural norms that can be defined on $E_1 \times \dots \times E_n$:

$$\begin{aligned} \|(x_1, \dots, x_n)\|_1 &= \|x_1\|_{E_1} + \dots + \|x_n\|_{E_n}, \\ \|(x_1, \dots, x_n)\|_2 &= \left(\|x_1\|_{E_1}^2 + \dots + \|x_n\|_{E_n}^2 \right)^{\frac{1}{2}}, \\ \|(x_1, \dots, x_n)\|_\infty &= \max \{ \|x_1\|_{E_1}, \dots, \|x_n\|_{E_n} \}. \end{aligned}$$

It is easy to show that

$$\|(x_1, \dots, x_n)\|_\infty \leq \|(x_1, \dots, x_n)\|_2 \leq \|(x_1, \dots, x_n)\|_1 \leq n\|(x_1, \dots, x_n)\|_\infty,$$

so these norms define the same topology, which is the product topology. It can also be verified that when $E_i = \mathbb{R}$, with the standard topology induced by $|x - y|$, the topology product on \mathbb{R}^n is the standard topology induced by the Euclidean norm.

Definition 37.13. Two metrics d and d' on a space E are *equivalent* if they induce the same topology \mathcal{O} on E (i.e., they define the same family \mathcal{O} of open sets). Similarly, two norms $\|\cdot\|$ and $\|\cdot'\|$ on a space E are *equivalent* if they induce the same topology \mathcal{O} on E .

Given a topological space (E, \mathcal{O}) , it is often useful, as in Proposition 37.7, to define the topology \mathcal{O} in terms of a subfamily \mathcal{B} of subsets of E .

Definition 37.14. We say that a family \mathcal{B} of subsets of E is a *basis for the topology* \mathcal{O} , if \mathcal{B} is a subset of \mathcal{O} , and if every open set U in \mathcal{O} can be obtained as some union (possibly infinite) of sets in \mathcal{B} (agreeing that the empty union is the empty set).

For example, given any metric space (E, d) , $\mathcal{B} = \{B_0(a, \rho) \mid a \in E, \rho > 0\}$. In particular, if $d = \|\cdot\|_2$, the open intervals form a basis for \mathbb{R} , while the open disks form a basis for \mathbb{R}^2 . The open rectangles also form a basis for \mathbb{R}^2 with the standard topology. See Figure 37.13.

It is immediately verified that if a family $\mathcal{B} = (U_i)_{i \in I}$ is a basis for the topology of (E, \mathcal{O}) , then $E = \bigcup_{i \in I} U_i$, and the intersection of any two sets $U_i, U_j \in \mathcal{B}$ is the union of some sets in the family \mathcal{B} (again, agreeing that the empty union is the empty set). Conversely, a family \mathcal{B} with these properties is the basis of the topology obtained by forming arbitrary unions of sets in \mathcal{B} .

Definition 37.15. A *subbasis for* \mathcal{O} is a family \mathcal{S} of subsets of E , such that the family \mathcal{B} of all finite intersections of sets in \mathcal{S} (including E itself, in case of the empty intersection) is a basis of \mathcal{O} . See Figure 37.13.

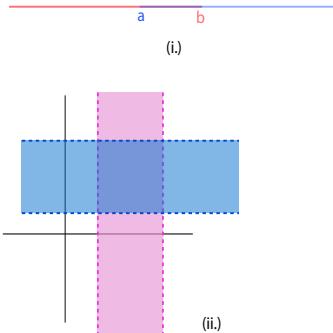

Figure 37.13: Figure (i.) shows that the set of infinite open intervals forms a subbasis for \mathbb{R} . Figure (ii.) shows that the infinite open strips form a subbasis for \mathbb{R}^2 .

The following proposition gives useful criteria for determining whether a family of open subsets is a basis of a topological space.

Proposition 37.8. Given a topological space (E, \mathcal{O}) and a family \mathcal{B} of open subsets in \mathcal{O} the following properties hold:

- (1) The family \mathcal{B} is a basis for the topology \mathcal{O} iff for every open set $U \in \mathcal{O}$ and every $x \in U$, there is some $B \in \mathcal{B}$ such that $x \in B$ and $B \subseteq U$. See Figure 37.14.
- (2) The family \mathcal{B} is a basis for the topology \mathcal{O} iff
 - (a) For every $x \in E$, there is some $B \in \mathcal{B}$ such that $x \in B$.

- (b) For any two open subsets, $B_1, B_2 \in \mathcal{B}$, for every $x \in E$, if $x \in B_1 \cap B_2$, then there is some $B_3 \in \mathcal{B}$ such that $x \in B_3$ and $B_3 \subseteq B_1 \cap B_2$. See Figure 37.15.

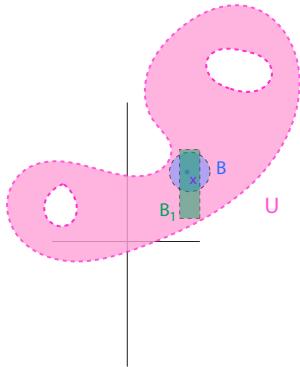

Figure 37.14: Given an open subset U of \mathbb{R}^2 and $x \in U$, there exists an open ball B containing x with $B \subset U$. There also exists an open rectangle B_1 containing x with $B_1 \subset U$.

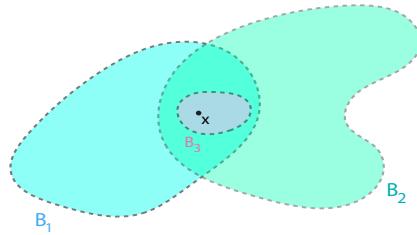

Figure 37.15: A schematic illustration of Condition (b) in Proposition 37.8.

We now consider the fundamental property of continuity.

37.3 Continuous Functions, Limits

Definition 37.16. Let (E, \mathcal{O}_E) and (F, \mathcal{O}_F) be topological spaces, and let $f: E \rightarrow F$ be a function. For every $a \in E$, we say that f is continuous at a , if for every open set $V \in \mathcal{O}_F$ containing $f(a)$, there is some open set $U \in \mathcal{O}_E$ containing a , such that, $f(U) \subseteq V$. See Figure 37.16. We say that f is continuous if it is continuous at every $a \in E$.

Define a *neighborhood* of $a \in E$ as any subset N of E containing some open set $O \in \mathcal{O}$ such that $a \in O$. If f is continuous at a and N is any neighborhood of $f(a)$, there is some open set $V \subseteq N$ containing $f(a)$, and since f is continuous at a , there is some open set U containing a , such that $f(U) \subseteq V$. Since $V \subseteq N$, the open set U is a subset of $f^{-1}(N)$

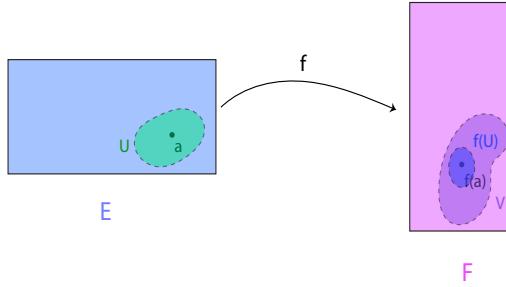

Figure 37.16: A schematic illustration of Definition 37.16.

containing a , and $f^{-1}(N)$ is a neighborhood of a . Conversely, if $f^{-1}(N)$ is a neighborhood of a whenever N is any neighborhood of $f(a)$, it is immediate that f is continuous at a . See Figure 37.17.

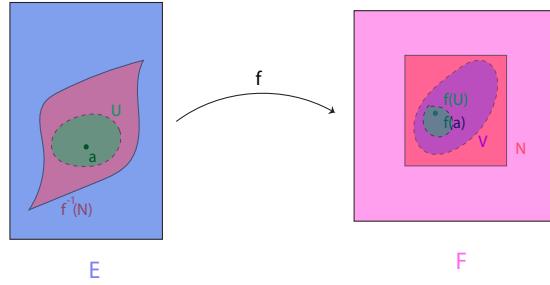

Figure 37.17: A schematic illustration of the neighborhood condition.

It is easy to see that Definition 37.16 is equivalent to the following statements.

Proposition 37.9. *Let (E, \mathcal{O}_E) and (F, \mathcal{O}_F) be topological spaces, and let $f: E \rightarrow F$ be a function. For every $a \in E$, the function f is continuous at $a \in E$ iff for every neighborhood N of $f(a) \in F$, then $f^{-1}(N)$ is a neighborhood of a . The function f is continuous on E iff $f^{-1}(V)$ is an open set in \mathcal{O}_E for every open set $V \in \mathcal{O}_F$.*

If E and F are metric spaces defined by metrics d_E and d_F , we can show easily that f is continuous at a iff

for every $\epsilon > 0$, there is some $\eta > 0$, such that, for every $x \in E$,

$$\text{if } d_E(a, x) \leq \eta, \text{ then } d_F(f(a), f(x)) \leq \epsilon.$$

Similarly, if E and F are normed vector spaces defined by norms $\| \|_E$ and $\| \|_F$, we can show easily that f is continuous at a iff

for every $\epsilon > 0$, there is some $\eta > 0$, such that, for every $x \in E$,

$$\text{if } \|x - a\|_E \leq \eta, \text{ then } \|f(x) - f(a)\|_F \leq \epsilon.$$

It is worth noting that continuity is a topological notion, in the sense that equivalent metrics (or equivalent norms) define exactly the same notion of continuity.

Definition 37.17. If (E, \mathcal{O}_E) and (F, \mathcal{O}_F) are topological spaces, and $f: E \rightarrow F$ is a function, for every nonempty subset $A \subseteq E$ of E , we say that f is *continuous on A* if the restriction of f to A is continuous with respect to (A, \mathcal{U}) and (F, \mathcal{O}_F) , where \mathcal{U} is the subspace topology induced by \mathcal{O}_E on A .

Given a product $E_1 \times \cdots \times E_n$ of topological spaces, as usual, we let $\pi_i: E_1 \times \cdots \times E_n \rightarrow E_i$ be the projection function such that, $\pi_i(x_1, \dots, x_n) = x_i$. It is immediately verified that each π_i is continuous.

Given a topological space (E, \mathcal{O}) , we say that a point $a \in E$ is *isolated* if $\{a\}$ is an open set in \mathcal{O} . Then if (E, \mathcal{O}_E) and (F, \mathcal{O}_F) are topological spaces, any function $f: E \rightarrow F$ is continuous at every isolated point $a \in E$. In the discrete topology, every point is isolated.

In a nontrivial normed vector space $(E, \|\cdot\|)$ (with $E \neq \{0\}$), no point is isolated. To show this, we show that every open ball $B_0(u, \rho)$ contains some vectors different from u . Indeed, since E is nontrivial, there is some $v \in E$ such that $v \neq 0$, and thus $\lambda = \|v\| > 0$ (by (N1)). Let

$$w = u + \frac{\rho}{\lambda + 1} v.$$

Since $v \neq 0$ and $\rho > 0$, we have $w \neq u$. Then,

$$\|w - u\| = \left\| \frac{\rho}{\lambda + 1} v \right\| = \frac{\rho\lambda}{\lambda + 1} < \rho,$$

which shows that $\|w - u\| < \rho$, for $w \neq u$.

The following proposition is easily shown.

Proposition 37.10. Given topological spaces (E, \mathcal{O}_E) , (F, \mathcal{O}_F) , and (G, \mathcal{O}_G) , and two functions $f: E \rightarrow F$ and $g: F \rightarrow G$, if f is continuous at $a \in E$ and g is continuous at $f(a) \in F$, then $g \circ f: E \rightarrow G$ is continuous at $a \in E$. Given n topological spaces (F_i, \mathcal{O}_i) , for every function $f: E \rightarrow F_1 \times \cdots \times F_n$, then f is continuous at $a \in E$ iff every $f_i: E \rightarrow F_i$ is continuous at a , where $f_i = \pi_i \circ f$.

One can also show that in a metric space (E, d) , the distance $d: E \times E \rightarrow \mathbb{R}$ is continuous, where $E \times E$ has the product topology. By the triangle inequality, we have

$$d(x, y) \leq d(x, x_0) + d(x_0, y_0) + d(y_0, y) = d(x_0, y_0) + d(x_0, x) + d(y_0, y)$$

and

$$d(x_0, y_0) \leq d(x_0, x) + d(x, y) + d(y, y_0) = d(x, y) + d(x_0, x) + d(y_0, y).$$

Consequently,

$$|d(x, y) - d(x_0, y_0)| \leq d(x_0, x) + d(y_0, y),$$

which proves that d is continuous at (x_0, y_0) . In fact this shows that d is uniformly continuous; see Definition 37.36.

Given any nonempty subset A of E , by Proposition 37.2, the map $x \mapsto d(x, A)$ is continuous (in fact, uniformly continuous).

Similarly, for a normed vector space $(E, \| \cdot \|)$, the norm $\| \cdot \|: E \rightarrow \mathbb{R}$ is (uniformly) continuous.

Given a function $f: E_1 \times \cdots \times E_n \rightarrow F$, we can fix $n - 1$ of the arguments, say $a_1, \dots, a_{i-1}, a_{i+1}, \dots, a_n$, and view f as a function of the remaining argument,

$$x_i \mapsto f(a_1, \dots, a_{i-1}, x_i, a_{i+1}, \dots, a_n),$$

where $x_i \in E_i$. If f is continuous, it is clear that each f_i is continuous.

One should be careful that the converse is false! For example, consider the function $f: \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R}$, defined such that,

$$f(x, y) = \frac{xy}{x^2 + y^2} \quad \text{if } (x, y) \neq (0, 0), \quad \text{and} \quad f(0, 0) = 0.$$

The function f is continuous on $\mathbb{R} \times \mathbb{R} - \{(0, 0)\}$, but on the line $y = mx$, with $m \neq 0$, we have $f(x, y) = \frac{m}{1+m^2} \neq 0$, and thus, on this line, $f(x, y)$ does not approach 0 when (x, y) approaches $(0, 0)$. See Figure 37.18.

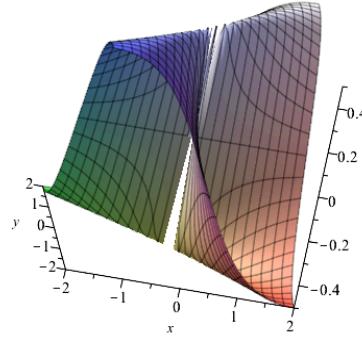

Figure 37.18: The graph of $f(x, y) = \frac{xy}{x^2 + y^2}$ for $(x, y) \neq (0, 0)$. The bottom of this graph, which shows the approach along the line $y = -x$, does not have a z value of 0.

The following proposition is useful for showing that real-valued functions are continuous.

Proposition 37.11. *If E is a topological space, and $(\mathbb{R}, |x - y|)$ the reals under the standard topology, for any two functions $f: E \rightarrow \mathbb{R}$ and $g: E \rightarrow \mathbb{R}$, for any $a \in E$, for any $\lambda \in \mathbb{R}$, if f and g are continuous at a , then $f + g$, λf , $f \cdot g$, are continuous at a , and f/g is continuous at a if $g(a) \neq 0$.*

Proof. Left as an exercise. □

Using Proposition 37.11, we can show easily that every real polynomial function is continuous.

The notion of isomorphism of topological spaces is defined as follows.

Definition 37.18. Let (E, \mathcal{O}_E) and (F, \mathcal{O}_F) be topological spaces, and let $f: E \rightarrow F$ be a function. We say that f is a homeomorphism between E and F if f is bijective, and both $f: E \rightarrow F$ and $f^{-1}: F \rightarrow E$ are continuous.

 One should be careful that a bijective continuous function $f: E \rightarrow F$ is not necessarily a homeomorphism. For example, if $E = \mathbb{R}$ with the discrete topology, and $F = \mathbb{R}$ with the standard topology, the identity is not a homeomorphism. Another interesting example involving a parametric curve is given below. Let $L: \mathbb{R} \rightarrow \mathbb{R}^2$ be the function, defined such that,

$$\begin{aligned} L_1(t) &= \frac{t(1+t^2)}{1+t^4}, \\ L_2(t) &= \frac{t(1-t^2)}{1+t^4}. \end{aligned}$$

If we think of $(x(t), y(t)) = (L_1(t), L_2(t))$ as a geometric point in \mathbb{R}^2 , the set of points $(x(t), y(t))$ obtained by letting t vary in \mathbb{R} from $-\infty$ to $+\infty$, defines a curve having the shape of a “figure eight,” with self-intersection at the origin, called the “lemniscate of Bernoulli.” See Figure 37.19. The map L is continuous, and in fact bijective, but its inverse L^{-1} is not continuous. Indeed, when we approach the origin on the branch of the curve in the upper left quadrant (i.e., points such that, $x \leq 0, y \geq 0$), then t goes to $-\infty$, and when we approach the origin on the branch of the curve in the lower right quadrant (i.e., points such that, $x \geq 0, y \leq 0$), then t goes to $+\infty$.

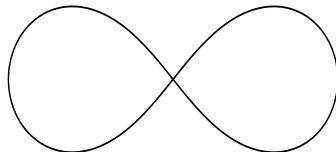

Figure 37.19: The lemniscate of Bernoulli.

We also review the concept of limit of a sequence. Given any set E , a *sequence* is any function $x: \mathbb{N} \rightarrow E$, usually denoted by $(x_n)_{n \in \mathbb{N}}$, or $(x_n)_{n \geq 0}$, or even by (x_n) .

Definition 37.19. Given a topological space (E, \mathcal{O}) , we say that a sequence $(x_n)_{n \in \mathbb{N}}$ converges to some $a \in E$ if for every open set U containing a , there is some $n_0 \geq 0$, such that, $x_n \in U$, for all $n \geq n_0$. We also say that a is a limit of $(x_n)_{n \in \mathbb{N}}$. See Figure 37.20.

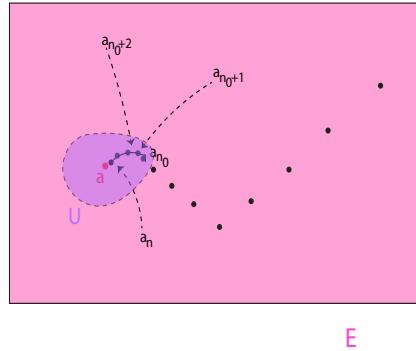

Figure 37.20: A schematic illustration of Definition 37.19.

When E is a metric space with metric d , it is easy to show that this is equivalent to the fact that,

for every $\epsilon > 0$, there is some $n_0 \geq 0$, such that, $d(x_n, a) \leq \epsilon$, for all $n \geq n_0$.

When E is a normed vector space with norm $\|\cdot\|$, it is easy to show that this is equivalent to the fact that,

for every $\epsilon > 0$, there is some $n_0 \geq 0$, such that, $\|x_n - a\| \leq \epsilon$, for all $n \geq n_0$.

The following proposition shows the importance of the Hausdorff separation axiom.

Proposition 37.12. Given a topological space (E, \mathcal{O}) , if the Hausdorff separation axiom holds, then every sequence has at most one limit.

Proof. Left as an exercise. □

It is worth noting that the notion of limit is topological, in the sense that a sequence converge to a limit b iff it converges to the same limit b in any equivalent metric (and similarly for equivalent norms).

If E is a metric space and if A is a subset of E , there is a convenient way of showing that a point $x \in E$ belongs to the closure \overline{A} of A in terms of sequences.

Proposition 37.13. Given any metric space (E, d) , for any subset A of E and any point $x \in E$, we have $x \in \overline{A}$ iff there is a sequence (a_n) of points $a_n \in A$ converging to x .

Proof. If the sequence (a_n) of points $a_n \in A$ converges to x , then for every open subset U of E containing x , there is some n_0 such that $a_n \in U$ for all $n \geq n_0$, so $U \cap A \neq \emptyset$, and Proposition 37.4 implies that $x \in \overline{A}$.

Conversely, assume that $x \in \overline{A}$. Then for every $n \geq 1$, consider the open ball $B_0(x, 1/n)$. By Proposition 37.4, we have $B_0(x, 1/n) \cap A \neq \emptyset$, so we can pick some $a_n \in B_0(x, 1/n) \cap A$. This way, we define a sequence (a_n) of points in A , and by construction $d(x, a_n) < 1/n$ for all $n \geq 1$, so the sequence (a_n) converges to x . \square

We still need one more concept of limit for functions.

Definition 37.20. Let (E, \mathcal{O}_E) and (F, \mathcal{O}_F) be topological spaces, let A be some nonempty subset of E , and let $f: A \rightarrow F$ be a function. For any $a \in \overline{A}$ and any $b \in F$, we say that $f(x)$ approaches b as x approaches a with values in A if for every open set $V \in \mathcal{O}_F$ containing b , there is some open set $U \in \mathcal{O}_E$ containing a , such that, $f(U \cap A) \subseteq V$. See Figure 37.21. This is denoted by

$$\lim_{x \rightarrow a, x \in A} f(x) = b.$$

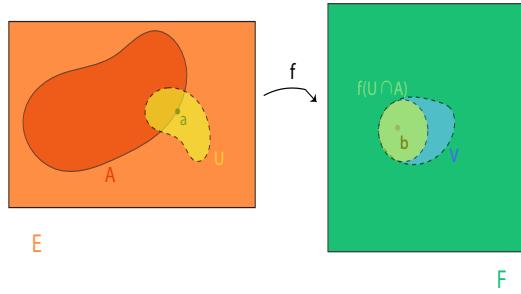

Figure 37.21: A schematic illustration of Definition 37.20.

First, note that by Proposition 37.4, since $a \in \overline{A}$, for every open set U containing a , we have $U \cap A \neq \emptyset$, and the definition is nontrivial. Also, even if $a \in A$, the value $f(a)$ of f at a plays no role in this definition. When E and F are metric space with metrics d_E and d_F , it can be shown easily that the definition can be stated as follows:

For every $\epsilon > 0$, there is some $\eta > 0$, such that, for every $x \in A$,

$$\text{if } d_E(x, a) \leq \eta, \text{ then } d_F(f(x), b) \leq \epsilon.$$

When E and F are normed vector spaces with norms $\| \cdot \|_E$ and $\| \cdot \|_F$, it can be shown easily that the definition can be stated as follows:

For every $\epsilon > 0$, there is some $\eta > 0$, such that, for every $x \in A$,

$$\text{if } \|x - a\|_E \leq \eta, \text{ then } \|f(x) - b\|_F \leq \epsilon.$$

We have the following result relating continuity at a point and the previous notion.

Proposition 37.14. *Let (E, \mathcal{O}_E) and (F, \mathcal{O}_F) be two topological spaces, and let $f: E \rightarrow F$ be a function. For any $a \in E$, the function f is continuous at a iff $f(x)$ approaches $f(a)$ when x approaches a (with values in E).*

Proof. Left as a trivial exercise. \square

Another important proposition relating the notion of convergence of a sequence to continuity, is stated without proof.

Proposition 37.15. *Let (E, \mathcal{O}_E) and (F, \mathcal{O}_F) be two topological spaces, and let $f: E \rightarrow F$ be a function.*

- (1) *If f is continuous, then for every sequence $(x_n)_{n \in \mathbb{N}}$ in E , if (x_n) converges to a , then $(f(x_n))$ converges to $f(a)$.*
- (2) *If E is a metric space, and $(f(x_n))$ converges to $f(a)$ whenever (x_n) converges to a , for every sequence $(x_n)_{n \in \mathbb{N}}$ in E , then f is continuous.*

A special case of Definition 37.20 will be used when E and F are (nontrivial) normed vector spaces with norms $\|\cdot\|_E$ and $\|\cdot\|_F$. Let U be any nonempty open subset of E . We showed earlier that E has no isolated points and that every set $\{v\}$ is closed, for every $v \in E$. Since E is nontrivial, for every $v \in U$, there is a nontrivial open ball contained in U (an open ball not reduced to its center). Then, for every $v \in U$, $A = U - \{v\}$ is open and nonempty, and clearly, $v \in \overline{A}$. For any $v \in U$, if $f(x)$ approaches b when x approaches v with values in $A = U - \{v\}$, we say that $f(x)$ approaches b when x approaches v with values $\neq v$ in U . This is denoted by

$$\lim_{x \rightarrow v, x \in U, x \neq v} f(x) = b.$$

Remark: Variations of the above case show up in the following case: $E = \mathbb{R}$, and F is some arbitrary topological space. Let A be some nonempty subset of \mathbb{R} , and let $f: A \rightarrow F$ be some function. For any $a \in A$, we say that f is continuous on the right at a if

$$\lim_{x \rightarrow a, x \in A \cap [a, +\infty)} f(x) = f(a).$$

We can define continuity on the left at a in a similar fashion.

Let us consider another variation. Let A be some nonempty subset of \mathbb{R} , and let $f: A \rightarrow F$ be some function. For any $a \in A$, we say that f has a discontinuity of the first kind at a if

$$\lim_{x \rightarrow a, x \in A \cap (-\infty, a)} f(x) = f(a_-)$$

and

$$\lim_{x \rightarrow a, x \in A \cap (a, +\infty)} f(x) = f(a_+)$$

both exist, and either $f(a_-) \neq f(a)$, or $f(a_+) \neq f(a)$.

Note that it is possible that $f(a_-) = f(a_+)$, but f is still discontinuous at a if this common value differs from $f(a)$. Functions defined on a nonempty subset of \mathbb{R} , and that are continuous, except for some points of discontinuity of the first kind, play an important role in analysis.

We now turn to connectivity properties of topological spaces.

37.4 Connected Sets

Connectivity properties of topological spaces play a very important role in understanding the topology of surfaces. This section gathers the facts needed to have a good understanding of the classification theorem for compact surfaces (with boundary). The main references are Ahlfors and Sario [2] and Massey [121, 122]. For general background on topology, geometry, and algebraic topology, we also highly recommend Bredon [30] and Fulton [67].

Definition 37.21. A topological space (E, \mathcal{O}) is *connected* if the only subsets of E that are both open and closed are the empty set and E itself. Equivalently, (E, \mathcal{O}) is connected if E cannot be written as the union $E = U \cup V$ of two disjoint nonempty open sets U, V , or if E cannot be written as the union $E = U \cup V$ of two disjoint nonempty closed sets. A subset, $S \subseteq E$, is *connected* if it is connected in the subspace topology on S induced by (E, \mathcal{O}) . See Figure 37.22. A connected open set is called a *region* and a closed set is a *closed region* if its interior is a connected (open) set.

The definition of connectivity is meant to capture the fact that a connected space S is “one piece.” Given the metric space $(\mathbb{R}^n, \| \cdot \|_2)$, the quintessential examples of connected spaces are $B_0(a, \rho)$ and $B(a, \rho)$. In particular, the following standard proposition characterizing the connected subsets of \mathbb{R} can be found in most topology texts (for example, Munkres [131], Schwartz [150]). For the sake of completeness, we give a proof.

Proposition 37.16. *A subset of the real line, \mathbb{R} , is connected iff it is an interval, i.e., of the form $[a, b]$, $(a, b]$, where $a = -\infty$ is possible, $[a, b)$, where $b = +\infty$ is possible, or (a, b) , where $a = -\infty$ or $b = +\infty$ is possible.*

Proof. Assume that A is a connected nonempty subset of \mathbb{R} . The cases where $A = \emptyset$ or A consists of a single point are trivial. Otherwise, we show that whenever $a, b \in A$, $a < b$, then the entire interval $[a, b]$ is a subset of A . Indeed, if this was not the case, there would be some $c \in (a, b)$ such that $c \notin A$, and then we could write $A = ((-\infty, c) \cap A) \cup ((c, +\infty) \cap A)$, where $(-\infty, c) \cap A$ and $(c, +\infty) \cap A$ are nonempty and disjoint open subsets of A , contradicting the fact that A is connected. It follows easily that A must be an interval.

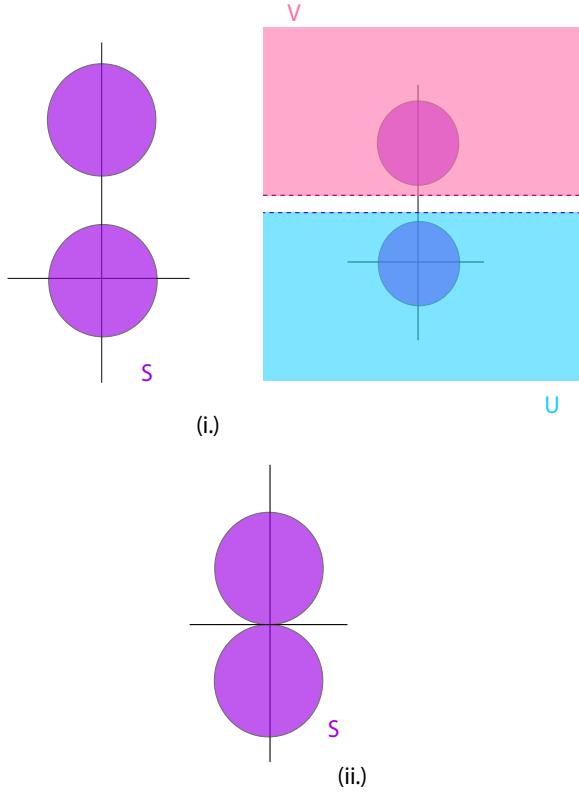

Figure 37.22: Figure (i) shows that the union of two disjoint disks in \mathbb{R}^2 is a disconnected set since each circle can be separated by open half regions. Figure (ii) is an example of a connected subset of \mathbb{R}^2 since the two disks can not be separated by open sets.

Conversely, we show that an interval, I , must be connected. Let A be any nonempty subset of I which is both open and closed in I . We show that $I = A$. Fix any $x \in A$ and consider the set, R_x , of all y such that $[x, y] \subseteq A$. If the set R_x is unbounded, then $R_x = [x, +\infty)$. Otherwise, if this set is bounded, let b be its least upper bound. We claim that b is the right boundary of the interval I . Because A is closed in I , unless I is open on the right and b is its right boundary, we must have $b \in A$. In the first case, $A \cap [x, b) = I \cap [x, b) = [x, b)$. In the second case, because A is also open in I , unless b is the right boundary of the interval I (closed on the right), there is some open set $(b - \eta, b + \eta)$ contained in A , which implies that $[x, b + \eta/2] \subseteq A$, contradicting the fact that b is the least upper bound of the set R_x . Thus, b must be the right boundary of the interval I (closed on the right). A similar argument applies to the set, L_y , of all x such that $[x, y] \subseteq A$ and either L_y is unbounded, or its greatest lower bound a is the left boundary of I (open or closed on the left). In all cases, we showed that $A = I$, and the interval must be connected. \square

Intuitively, if a space is not connected, it is possible to define a continuous function which

is constant on disjoint “connected components” and which takes possibly distinct values on disjoint components. This can be stated in terms of the concept of a locally constant function.

Definition 37.22. Given two topological spaces X, Y , a function $f: X \rightarrow Y$ is *locally constant* if for every $x \in X$, there is an open set $U \subseteq X$ such that $x \in U$ and f is constant on U .

We claim that a locally constant function is continuous. In fact, we will prove that $f^{-1}(V)$ is open for every subset, $V \subseteq Y$ (not just for an open set V). It is enough to show that $f^{-1}(y)$ is open for every $y \in Y$, since for every subset $V \subseteq Y$,

$$f^{-1}(V) = \bigcup_{y \in V} f^{-1}(y),$$

and open sets are closed under arbitrary unions. However, either $f^{-1}(y) = \emptyset$ if $y \in Y - f(X)$ or f is constant on $U = f^{-1}(y)$ if $y \in f(X)$ (with value y), and since f is locally constant, for every $x \in U$, there is some open set, $W \subseteq X$, such that $x \in W$ and f is constant on W , which implies that $f(w) = y$ for all $w \in W$ and thus, that $W \subseteq U$, showing that U is a union of open sets and thus, is open. The following proposition shows that a space is connected iff every locally constant function is constant:

Proposition 37.17. *A topological space is connected iff every locally constant function is constant. See Figure 37.23.*

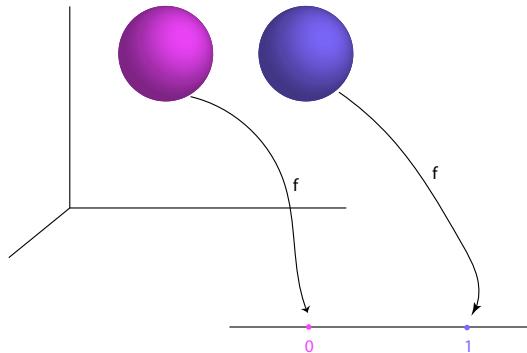

Figure 37.23: An example of a locally constant, but not constant, real-valued function f over the disconnected set consisting of the disjoint union of the two solid balls. On the pink ball, f is 0, while on the purple ball, f is 1.

Proof. First, assume that X is connected. Let $f: X \rightarrow Y$ be a locally constant function to some space Y and assume that f is not constant. Pick any $y \in f(X)$. Since f is not constant, $U_1 = f^{-1}(y) \neq X$, and of course, $U_1 \neq \emptyset$. We proved just before Proposition

37.17 that $f^{-1}(V)$ is open for every subset $V \subseteq Y$, and thus $U_1 = f^{-1}(y) = f^{-1}(\{y\})$ and $U_2 = f^{-1}(Y - \{y\})$ are both open, nonempty, and clearly $X = U_1 \cup U_2$ and U_1 and U_2 are disjoint. This contradicts the fact that X is connected and f must be constant.

Assume that every locally constant function $f: X \rightarrow Y$ is constant. If X is not connected, we can write $X = U_1 \cup U_2$, where both U_1, U_2 are open, disjoint, and nonempty. We can define the function, $f: X \rightarrow \mathbb{R}$, such that $f(x) = 1$ on U_1 and $f(x) = 0$ on U_2 . Since U_1 and U_2 are open, the function f is locally constant, and yet not constant, a contradiction. \square

A characterization on the connected subsets of \mathbb{R}^n is harder and requires the notion of arcwise connectedness. One of the most important properties of connected sets is that they are preserved by continuous maps.

Proposition 37.18. *Given any continuous map, $f: E \rightarrow F$, if $A \subseteq E$ is connected, then $f(A)$ is connected.*

Proof. If $f(A)$ is not connected, then there exist some nonempty open sets, U, V , in F such that $f(A) \cap U$ and $f(A) \cap V$ are nonempty and disjoint, and

$$f(A) = (f(A) \cap U) \cup (f(A) \cap V).$$

Then, $f^{-1}(U)$ and $f^{-1}(V)$ are nonempty and open since f is continuous and

$$A = (A \cap f^{-1}(U)) \cup (A \cap f^{-1}(V)),$$

with $A \cap f^{-1}(U)$ and $A \cap f^{-1}(V)$ nonempty, disjoint, and open in A , contradicting the fact that A is connected. \square

An important corollary of Proposition 37.18 is that for every continuous function, $f: E \rightarrow \mathbb{R}$, where E is a connected space, $f(E)$ is an interval. Indeed, this follows from Proposition 37.16. Thus, if f takes the values a and b where $a < b$, then f takes all values $c \in [a, b]$. This is a very important property known as the intermediate value theorem.

Even if a topological space is not connected, it turns out that it is the disjoint union of maximal connected subsets and these connected components are closed in E . In order to obtain this result, we need a few lemmas.

Lemma 37.19. *Given a topological space, E , for any family, $(A_i)_{i \in I}$, of (nonempty) connected subsets of E , if $A_i \cap A_j \neq \emptyset$ for all $i, j \in I$, then the union, $A = \bigcup_{i \in I} A_i$, of the family, $(A_i)_{i \in I}$, is also connected.*

Proof. Assume that $\bigcup_{i \in I} A_i$ is not connected. There exists two nonempty open subsets, U and V , of E such that $A \cap U$ and $A \cap V$ are disjoint and nonempty and such that

$$A = (A \cap U) \cup (A \cap V).$$

Now, for every $i \in I$, we can write

$$A_i = (A_i \cap U) \cup (A_i \cap V),$$

where $A_i \cap U$ and $A_i \cap V$ are disjoint, since $A_i \subseteq A$ and $A \cap U$ and $A \cap V$ are disjoint. Since A_i is connected, either $A_i \cap U = \emptyset$ or $A_i \cap V = \emptyset$. This implies that either $A_i \subseteq A \cap U$ or $A_i \subseteq A \cap V$. However, by assumption, $A_i \cap A_j \neq \emptyset$, for all $i, j \in I$, and thus, either both $A_i \subseteq A \cap U$ and $A_j \subseteq A \cap U$, or both $A_i \subseteq A \cap V$ and $A_j \subseteq A \cap V$, since $A \cap U$ and $A \cap V$ are disjoint. Thus, we conclude that either $A_i \subseteq A \cap U$ for all $i \in I$, or $A_i \subseteq A \cap V$ for all $i \in I$. But this proves that either

$$A = \bigcup_{i \in I} A_i \subseteq A \cap U,$$

or

$$A = \bigcup_{i \in I} A_i \subseteq A \cap V,$$

contradicting the fact that both $A \cap U$ and $A \cap V$ are disjoint and nonempty. Thus, A must be connected. \square

In particular, the above lemma applies when the connected sets in a family $(A_i)_{i \in I}$ have a point in common.

Lemma 37.20. *If A is a connected subset of a topological space, E , then for every subset, B , such that $A \subseteq B \subseteq \overline{A}$, where \overline{A} is the closure of A in E , the set B is connected.*

Proof. If B is not connected, then there are two nonempty open subsets, U, V , of E such that $B \cap U$ and $B \cap V$ are disjoint and nonempty, and

$$B = (B \cap U) \cup (B \cap V).$$

Since $A \subseteq B$, the above implies that

$$A = (A \cap U) \cup (A \cap V),$$

and since A is connected, either $A \cap U = \emptyset$, or $A \cap V = \emptyset$. Without loss of generality, assume that $A \cap V = \emptyset$, which implies that $A \subseteq A \cap U \subseteq B \cap U$. However, $B \cap U$ is closed in the subspace topology for B and since $B \subseteq \overline{A}$ and \overline{A} is closed in E , the closure of A in B w.r.t. the subspace topology of B is clearly $B \cap \overline{A} = B$, which implies that $B \subseteq B \cap U$ (since the closure is the smallest closed set containing the given set). Thus, $B \cap V = \emptyset$, a contradiction. \square

In particular, Lemma 37.20 shows that if A is a connected subset, then its closure, \overline{A} , is also connected. We are now ready to introduce the connected components of a space.

Definition 37.23. Given a topological space, (E, \mathcal{O}) , we say that two points, $a, b \in E$, are *connected* if there is some connected subset, A , of E such that $a \in A$ and $b \in A$.

It is immediately verified that the relation “ a and b are connected in E ” is an equivalence relation. Only transitivity is not obvious, but it follows immediately as a special case of Lemma 37.19. Thus, the above equivalence relation defines a partition of E into nonempty disjoint *connected components*. The following proposition is easily proved using Lemma 37.19 and Lemma 37.20:

Proposition 37.21. *Given any topological space, E , for any $a \in E$, the connected component containing a is the largest connected set containing a . The connected components of E are closed.*

The notion of a locally connected space is also useful.

Definition 37.24. A topological space, (E, \mathcal{O}) , is *locally connected* if for every $a \in E$, for every neighborhood, V , of a , there is a connected neighborhood, U , of a such that $U \subseteq V$. See Figure 37.24.

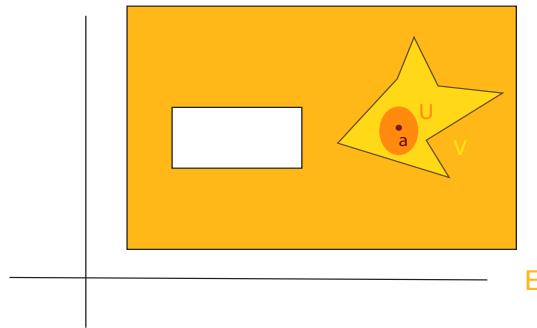

Figure 37.24: The topological space E , which is homeomorphic to an annulus, is locally connected since each point is surrounded by a small disk contained in E .

As we shall see in a moment, it would be equivalent to require that E has a basis of connected open sets.

There are connected spaces that are not locally connected and there are locally connected spaces that are not connected. The two properties are independent. For example, the subspace of \mathbb{R}^2 $S = \{(x, \sin(1/x)) \mid x > 0\} \cup \{(0, y) \mid -1 \leq y \leq 1\}$ is connected but not locally connected. See Figure 37.25. The subspace S of \mathbb{R} consisting $[0, 1] \cup [2, 3]$ is locally connected but not connected.

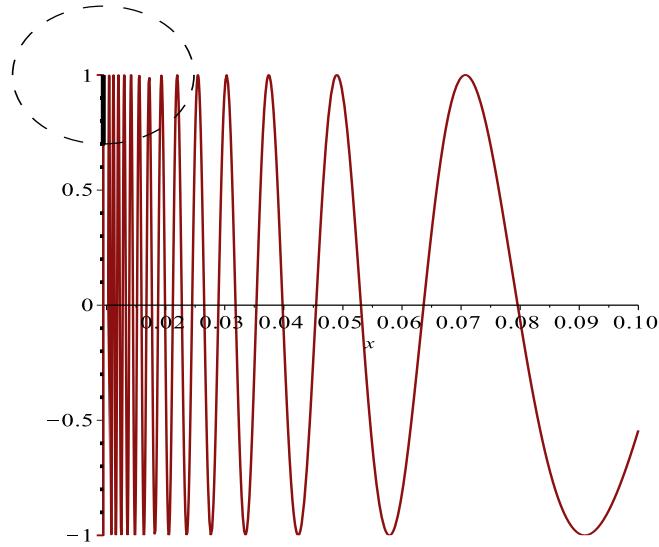

Figure 37.25: Let S be the graph of $f(x) = \sin(1/x)$ union the y -axis between -1 and 1 . This space is connected, but not locally connected.

Proposition 37.22. *A topological space, E , is locally connected iff for every open subset, A , of E , the connected components of A are open.*

Proof. Assume that E is locally connected. Let A be any open subset of E and let C be one of the connected components of A . For any $a \in C \subseteq A$, there is some connected neighborhood, U , of a such that $U \subseteq A$ and since C is a connected component of A containing a , we must have $U \subseteq C$. This shows that for every $a \in C$, there is some open subset containing a contained in C , so C is open.

Conversely, assume that for every open subset, A , of E , the connected components of A are open. Then, for every $a \in E$ and every neighborhood, U , of a , since U contains some open set A containing a , the interior, $\overset{\circ}{U}$, of U is an open set containing a and its connected components are open. In particular, the connected component C containing a is a connected open set containing a and contained in U . \square

Proposition 37.22 shows that in a locally connected space, the connected open sets form a basis for the topology. It is easily seen that \mathbb{R}^n is locally connected. Another very important property of surfaces and more generally, manifolds, is to be arcwise connected. The intuition is that any two points can be joined by a continuous arc of curve. This is formalized as follows.

Definition 37.25. Given a topological space, (E, \mathcal{O}) , an *arc* (or *path*) is a continuous map, $\gamma: [a, b] \rightarrow E$, where $[a, b]$ is a closed interval of the real line, \mathbb{R} . The point $\gamma(a)$ is the *initial point* of the arc and the point $\gamma(b)$ is the *terminal point* of the arc. We say that γ is an *arc joining $\gamma(a)$ and $\gamma(b)$* . See Figure 37.26. An arc is a *closed curve* if $\gamma(a) = \gamma(b)$. The set $\gamma([a, b])$ is the *trace* of the arc γ .

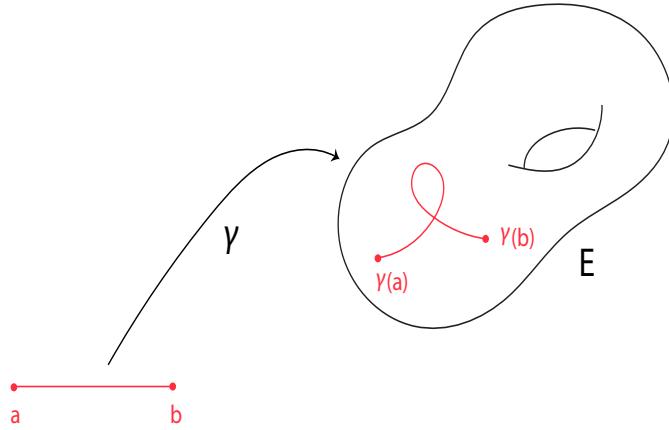

Figure 37.26: Let E be the torus with subspace topology induced from \mathbb{R}^3 with red arc $\gamma([a, b])$. The torus is both arcwise connected and locally arcwise connected.

Typically, $a = 0$ and $b = 1$.

One should not confuse an arc, $\gamma: [a, b] \rightarrow E$, with its trace. For example, γ could be constant, and thus, its trace reduced to a single point.

An arc is a *Jordan arc* if γ is a homeomorphism onto its trace. An arc, $\gamma: [a, b] \rightarrow E$, is a *Jordan curve* if $\gamma(a) = \gamma(b)$ and γ is injective on $[a, b]$. Since $[a, b]$ is connected, by Proposition 37.18, the trace $\gamma([a, b])$ of an arc is a connected subset of E .

Given two arcs $\gamma: [0, 1] \rightarrow E$ and $\delta: [0, 1] \rightarrow E$ such that $\gamma(1) = \delta(0)$, we can form a new arc defined as follows:

Definition 37.26. Given two arcs, $\gamma: [0, 1] \rightarrow E$ and $\delta: [0, 1] \rightarrow E$, such that $\gamma(1) = \delta(0)$, we can form their *composition* (or *product*), $\gamma\delta$, defined such that

$$\gamma\delta(t) = \begin{cases} \gamma(2t) & \text{if } 0 \leq t \leq 1/2; \\ \delta(2t - 1) & \text{if } 1/2 \leq t \leq 1. \end{cases}$$

The *inverse*, γ^{-1} , of the arc, γ , is the arc defined such that $\gamma^{-1}(t) = \gamma(1-t)$, for all $t \in [0, 1]$.

It is trivially verified that Definition 37.26 yields continuous arcs.

Definition 37.27. A topological space, E , is *arcwise connected* if for any two points, $a, b \in E$, there is an arc, $\gamma: [0, 1] \rightarrow E$, joining a and b , i.e., such that $\gamma(0) = a$ and $\gamma(1) = b$. A topological space, E , is *locally arcwise connected* if for every $a \in E$, for every neighborhood, V , of a , there is an arcwise connected neighborhood, U , of a such that $U \subseteq V$. See Figure 37.26.

The space \mathbb{R}^n is locally arcwise connected, since for any open ball, any two points in this ball are joined by a line segment. Manifolds and surfaces are also locally arcwise connected. Proposition 37.18 also applies to arcwise connectedness (this is a simple exercise). The following theorem is crucial to the theory of manifolds and surfaces:

Theorem 37.23. *If a topological space, E , is arcwise connected, then it is connected. If a topological space, E , is connected and locally arcwise connected, then E is arcwise connected.*

Proof. First, assume that E is arcwise connected. Pick any point, a , in E . Since E is arcwise connected, for every $b \in E$, there is a path, $\gamma_b: [0, 1] \rightarrow E$, from a to b and so,

$$E = \bigcup_{b \in E} \gamma_b([0, 1])$$

a union of connected subsets all containing a . By Lemma 37.19, E is connected.

Now assume that E is connected and locally arcwise connected. For any point $a \in E$, let F_a be the set of all points, b , such that there is an arc, $\gamma_b: [0, 1] \rightarrow E$, from a to b . Clearly, F_a contains a . We show that F_a is both open and closed. For any $b \in F_a$, since E is locally arcwise connected, there is an arcwise connected neighborhood U containing b (because E is a neighborhood of b). Thus, b can be joined to every point $c \in U$ by an arc, and since by the definition of F_a , there is an arc from a to b , the composition of these two arcs yields an arc from a to c , which shows that $c \in F_a$. But then $U \subseteq F_a$ and thus, F_a is open. See Figure 37.27 (i.). Now assume that b is in the complement of F_a . As in the previous case, there is some arcwise connected neighborhood U containing b . Thus, every point $c \in U$ can be joined to b by an arc. If there was an arc joining a to c , we would get an arc from a to b , contradicting the fact that b is in the complement of F_a . Thus, every point $c \in U$ is in the complement of F_a , which shows that U is contained in the complement of F_a , and thus, that the complement of F_a is open. See Figure 37.27 (ii.). Consequently, we have shown that F_a is both open and closed and since it is nonempty, we must have $E = F_a$, which shows that E is arcwise connected. \square

If E is locally arcwise connected, the above argument shows that the connected components of E are arcwise connected.

It is not true that a connected space is arcwise connected. For example, the space consisting of the graph of the function

$$f(x) = \sin(1/x),$$

where $x > 0$, together with the portion of the y -axis, for which $-1 \leq y \leq 1$, is connected, but not arcwise connected. See Figure 37.25.

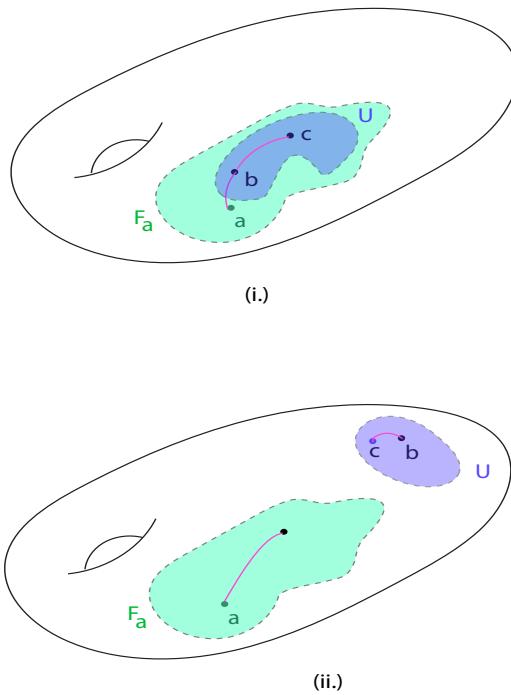

Figure 37.27: Schematic illustrations of the proof techniques that show F_a is both open and closed.

A trivial modification of the proof of Theorem 37.23 shows that in a normed vector space, E , a connected open set is arcwise connected by polygonal lines (i.e., arcs consisting of line segments). This is because in every open ball, any two points are connected by a line segment. Furthermore, if E is finite dimensional, these polygonal lines can be forced to be parallel to basis vectors.

We now consider compactness.

37.5 Compact Sets and Locally Compact Spaces

The property of compactness is very important in topology and analysis. We provide a quick review geared towards the study of manifolds, and for details, we refer the reader to Munkres [131], Schwartz [150]. In this section we will need to assume that the topological spaces are Hausdorff spaces. This is not a luxury, as many of the results are false otherwise.

We begin this section by providing the definition of compactness and describing a collection of compact spaces in \mathbb{R} . There are various equivalent ways of defining compactness. For our purposes, the most convenient way involves the notion of open cover.

Definition 37.28. Given a topological space E , for any subset A of E , an *open cover* $(U_i)_{i \in I}$ of A is a family of open subsets of E such that $A \subseteq \bigcup_{i \in I} U_i$. An *open subcover* of an open cover $(U_i)_{i \in I}$ of A is any subfamily $(U_j)_{j \in J}$ which is an open cover of A , with $J \subseteq I$. An open cover $(U_i)_{i \in I}$ of A is *finite* if I is finite. See Figure 37.28. The topological space E is *compact* if it is Hausdorff and for every open cover $(U_i)_{i \in I}$ of E , there is a finite open subcover $(U_j)_{j \in J}$ of E . Given any subset A of E , we say that A is *compact* if it is compact with respect to the subspace topology. We say that A is *relatively compact* if its closure \bar{A} is compact.

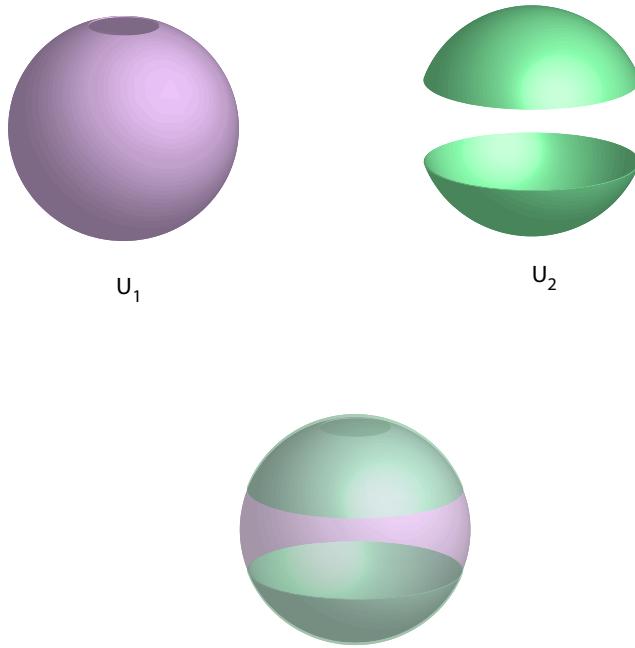

Figure 37.28: An open cover of S^2 using two open sets induced by the Euclidean topology of \mathbb{R}^3 .

It is immediately verified that a subset A of E is compact in the subspace topology relative to A iff for every open cover $(U_i)_{i \in I}$ of A by open subsets of E , there is a finite open subcover $(U_j)_{j \in J}$ of A . The property that every open cover contains a finite open subcover is often called the *Heine-Borel-Lebesgue* property. By considering complements, a Hausdorff space is compact iff for every family $(F_i)_{i \in I}$ of closed sets, if $\bigcap_{i \in I} F_i = \emptyset$, then $\bigcap_{j \in J} F_j = \emptyset$ for some finite subset J of I .

Definition 37.28 requires that a compact space be Hausdorff. There are books in which a compact space is not necessarily required to be Hausdorff. Following Schwartz, we prefer calling such a space *quasi-compact*.

Another equivalent and useful characterization can be given in terms of families having the finite intersection property.

Definition 37.29. A family $(F_i)_{i \in I}$ of sets has the *finite intersection property* if $\bigcap_{j \in J} F_j \neq \emptyset$ for every finite subset J of I .

Proposition 37.24. A topological Hausdorff space E is compact iff for every family $(F_i)_{i \in I}$ of closed sets having the finite intersection property, then $\bigcap_{i \in I} F_i \neq \emptyset$.

Proof. If E is compact and $(F_i)_{i \in I}$ is a family of closed sets having the finite intersection property, then $\bigcap_{i \in I} F_i$ cannot be empty, since otherwise we would have $\bigcap_{j \in J} F_j = \emptyset$ for some finite subset J of I , a contradiction. The converse is equally obvious. \square

Another useful consequence of compactness is as follows. For any family $(F_i)_{i \in I}$ of closed sets such that $F_{i+1} \subseteq F_i$ for all $i \in I$, if $\bigcap_{i \in I} F_i = \emptyset$, then $F_i = \emptyset$ for some $i \in I$. Indeed, there must be some finite subset J of I such that $\bigcap_{j \in J} F_j = \emptyset$, and since $F_{i+1} \subseteq F_i$ for all $i \in I$, we must have $F_j = \emptyset$ for the smallest F_j in $(F_j)_{j \in J}$. Using this fact, we note that \mathbb{R} is *not* compact. Indeed, the family of closed sets, $([n, +\infty))_{n \geq 0}$, is decreasing and has an empty intersection.

It is immediately verified that every finite union of compact subsets is compact. Similarly, every finite union of relatively compact subsets is relatively compact (use the fact that $\overline{A \cup B} = \overline{A} \cap \overline{B}$).

Given a metric space, if we define a *bounded subset* to be a subset that can be enclosed in some closed ball (of finite radius), then any nonbounded subset of a metric space is not compact. However, a closed interval $[a, b]$ of the real line is compact.

Proposition 37.25. Every closed interval, $[a, b]$, of the real line is compact.

Proof. We proceed by contradiction. Let $(U_i)_{i \in I}$ be any open cover of $[a, b]$ and assume that there is no finite open subcover. Let $c = (a + b)/2$. If both $[a, c]$ and $[c, b]$ had some finite open subcover, so would $[a, b]$, and thus, either $[a, c]$ does not have any finite subcover, or $[c, b]$ does not have any finite open subcover. Let $[a_1, b_1]$ be such a bad subinterval. The same argument applies and we split $[a_1, b_1]$ into two equal subintervals, one of which must be bad. Thus, having defined $[a_n, b_n]$ of length $(b - a)/2^n$ as an interval having no finite open subcover, splitting $[a_n, b_n]$ into two equal intervals, we know that at least one of the two has no finite open subcover and we denote such a bad interval by $[a_{n+1}, b_{n+1}]$. See Figure 37.29. The sequence (a_n) is nondecreasing and bounded from above by b , and thus, by a fundamental property of the real line, it converges to its least upper bound, α . Similarly, the sequence (b_n) is nonincreasing and bounded from below by a and thus, it converges to its greatest lower bound, β . Since $[a_n, b_n]$ has length $(b - a)/2^n$, we must have $\alpha = \beta$. However, the common limit $\alpha = \beta$ of the sequences (a_n) and (b_n) must belong to some open set, U_i , of the open cover and since U_i is open, it must contain some interval $[c, d]$ containing α . Then, because α is the common limit of the sequences (a_n) and (b_n) , there is some N such that the intervals $[a_n, b_n]$ are all contained in the interval $[c, d]$ for all $n \geq N$, which contradicts the fact that none of the intervals $[a_n, b_n]$ has a finite open subcover. Thus, $[a, b]$ is indeed compact. \square

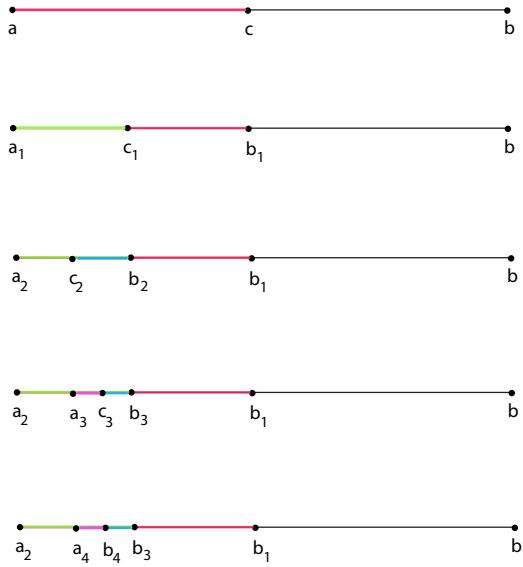

Figure 37.29: The first four stages of the nested interval construction utilized in the proof of Proposition 37.25.

The argument of Proposition 37.25 can be adapted to show that in \mathbb{R}^m , every closed set, $[a_1, b_1] \times \cdots \times [a_m, b_m]$, is compact. At every stage, we need to divide into 2^m subpieces instead of 2.

We next discuss some important properties of compact spaces. We begin with two separations axioms which only hold for Hausdorff spaces:

Proposition 37.26. *Given a topological Hausdorff space, E , for every compact subset, A , and every point, b , not in A , there exist disjoint open sets, U and V , such that $A \subseteq U$ and $b \in V$. See Figure 37.30. As a consequence, every compact subset is closed.*

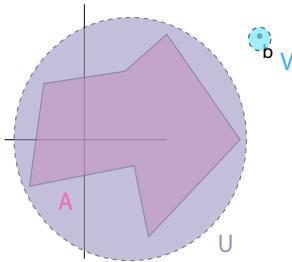

Figure 37.30: The compact set of \mathbb{R}^2 , A , is separated by any point in its complement.

Proof. Since E is Hausdorff, for every $a \in A$, there are some disjoint open sets, U_a and V_a , containing a and b respectively. Thus, the family, $(U_a)_{a \in A}$, forms an open cover of A . Since A is compact there is a finite open subcover, $(U_j)_{j \in J}$, of A , where $J \subseteq A$, and then $\bigcup_{j \in J} U_j$ is an open set containing A disjoint from the open set $\bigcap_{j \in J} V_j$ containing b . This shows that every point, b , in the complement of A belongs to some open set in this complement and thus, that the complement is open, i.e., that A is closed. See Figure 37.31. \square

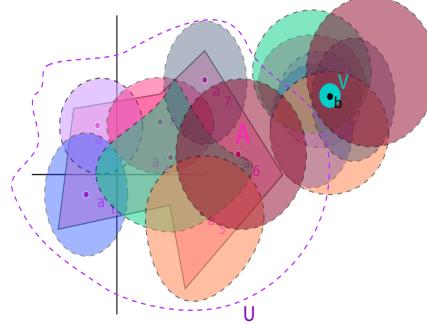

Figure 37.31: For the pink compact set A , U is the union of the seven disks which cover A , while V is the intersection of the seven open sets containing b .

Actually, the proof of Proposition 37.26 can be used to show the following useful property:

Proposition 37.27. *Given a topological Hausdorff space E , for every pair of compact disjoint subsets A and B , there exist disjoint open sets U and V , such that $A \subseteq U$ and $B \subseteq V$.*

Proof. We repeat the argument of Proposition 37.26 with B playing the role of b and use Proposition 37.26 to find disjoint open sets U_a containing $a \in A$, and V_a containing B . \square

The following proposition shows that in a compact topological space, every closed set is compact:

Proposition 37.28. *Given a compact topological space, E , every closed set is compact.*

Proof. Since A is closed, $E - A$ is open and from any open cover, $(U_i)_{i \in I}$, of A , we can form an open cover of E by adding $E - A$ to $(U_i)_{i \in I}$ and, since E is compact, a finite subcover, $(U_j)_{j \in J} \cup \{E - A\}$, of E can be extracted such that $(U_j)_{j \in J}$ is a finite subcover of A . See Figure 37.32. \square

Remark: Proposition 37.28 also holds for quasi-compact spaces, i.e., the Hausdorff separation property is not needed.

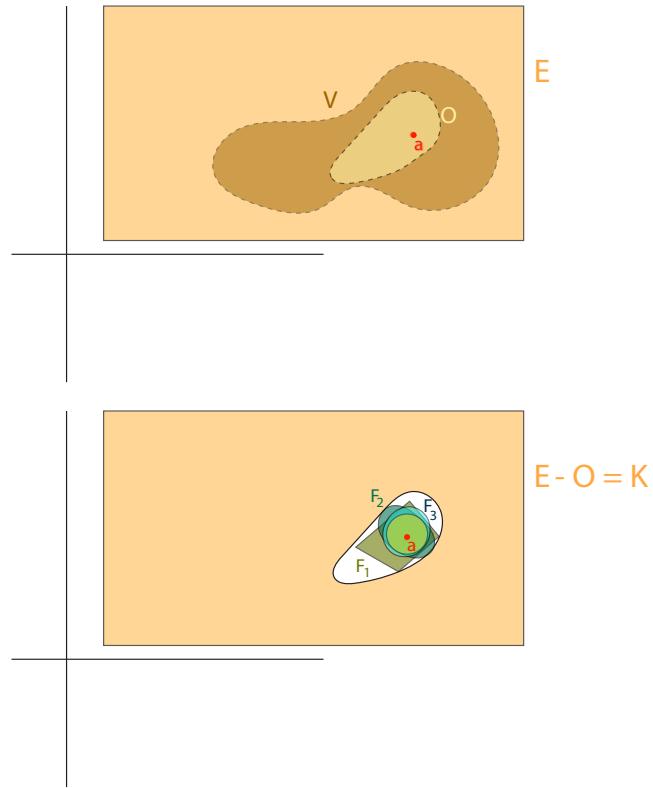

Figure 37.32: An illustration of the proof of Proposition 37.28. Both E and A are closed squares in \mathbb{R}^2 . Note that an open cover of A , namely the green circles, when combined with the yellow square annulus $E - A$ covers all of the yellow square E .

Putting Proposition 37.27 and Proposition 37.28 together, we note that if X is compact, then for every pair of disjoint closed sets A and B , there exist disjoint open sets U and V such that $A \subseteq U$ and $B \subseteq V$.

Definition 37.30. A topological space E is *normal* if every one-point set is closed, and for every pair of disjoint closed sets A and B , there exist disjoint open sets U and V such that $A \subseteq U$ and $B \subseteq V$. A topological space E is *regular* if every one-point set is closed, and for every point $a \in E$ and every closed subset B of E , if $a \notin B$, then there exist disjoint open sets U and V such that $a \in U$ and $B \subseteq V$.

It is clear that a normal space is regular, and a regular space is Hausdorff. There are examples of Hausdorff spaces that are not regular, and of regular spaces that are not normal.

We just observed that a compact space is normal. An important property of metrizable spaces is that they are normal.

Proposition 37.29. *Every metrizable space E is normal.*

Proof. Assume the topology of E is given by the metric d . Since B is closed and $A \cap B = \emptyset$, for every $a \in A$ since $a \notin \overline{B} = B$, there is some open ball $B_0(a, \epsilon_a)$ of radius $\epsilon_a > 0$ such that $B_0(a, \epsilon_a) \cap B = \emptyset$. Similarly, since A is closed and $A \cap B = \emptyset$, for every $b \in B$ there is some open ball $B_0(b, \epsilon_b)$ of radius $\epsilon_b > 0$ such that $B_0(b, \epsilon_b) \cap A = \emptyset$. Let

$$U = \bigcup_{a \in A} B_0(a, \epsilon_a/2), \quad V = \bigcup_{b \in B} B_0(b, \epsilon_b/2).$$

Then A and B are open sets such that $A \subseteq U$ and $B \subseteq V$, and we claim that $U \cap V = \emptyset$.

If not, then there is some $z \in U \cap V$, which implies that for some $a \in A$ and some $b \in B$, we have

$$z \in B_0(a, \epsilon_a/2) \cap B_0(b, \epsilon_b/2).$$

It follows that

$$d(a, b) \leq d(a, z) + d(z, b) < (\epsilon_a + \epsilon_b)/2.$$

If $\epsilon_a \leq \epsilon_b$, then $d(a, b) < \epsilon_b$, so $a \in B_0(b, \epsilon_b)$, contradicting the fact that $B_0(b, \epsilon_b) \cap A = \emptyset$. If $\epsilon_b \leq \epsilon_a$, then $d(a, b) < \epsilon_a$, so $b \in B_0(a, \epsilon_a)$, contradicting the fact that $B_0(a, \epsilon_a) \cap B = \emptyset$. \square

Compact spaces also have the following property.

Proposition 37.30. *Given a compact topological space, E , for every $a \in E$, for every neighborhood, V , of a , there exists a compact neighborhood, U , of a such that $U \subseteq V$. See Figure 37.33.*

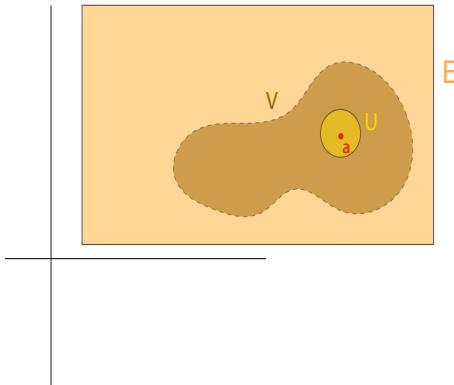

Figure 37.33: Let E be the peach square of \mathbb{R}^2 . Each point of E is contained in a compact neighborhood U , in this case the small closed yellow disk.

Proof. Since V is a neighborhood of a , there is some open subset, O , of V containing a . Then the complement, $K = E - O$, of O is closed and since E is compact, by Proposition 37.28, K is compact. Now, if we consider the family of all closed sets of the form, $K \cap F$, where F is any closed neighborhood of a , since $a \notin K$, this family has an empty intersection and thus, there is a finite number of closed neighborhood, F_1, \dots, F_n , of a , such that $K \cap F_1 \cap \dots \cap F_n = \emptyset$. Then, $U = F_1 \cap \dots \cap F_n$ is closed and hence by Proposition 37.28, a compact neighborhood of a contained in $O \subseteq V$. See Figure 37.34. \square

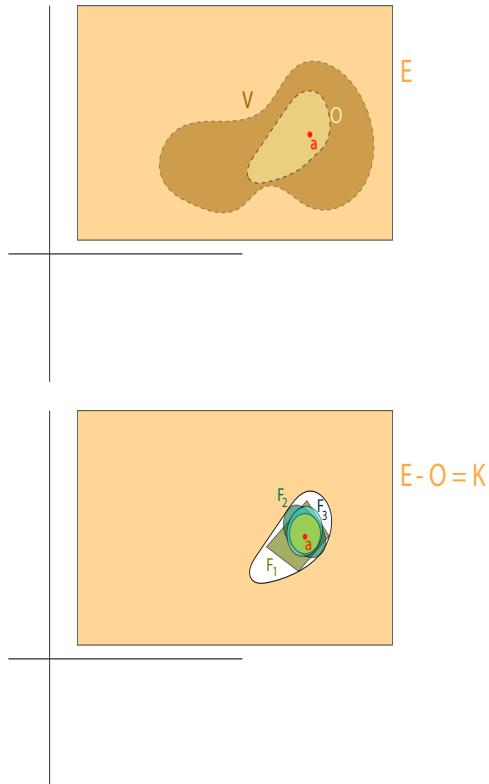

Figure 37.34: Let E be the peach square of \mathbb{R}^2 . The compact neighborhood of a , U , is the intersection of the closed sets F_1, F_2, F_3 , each of which are contained in the complement of K .

It can be shown that in a normed vector space of finite dimension, a subset is compact iff it is closed and bounded. For \mathbb{R}^n the proof is simple.

In a normed vector space of infinite dimension, there are closed and bounded sets that are not compact!

More could be said about compactness in metric spaces but we will only need the notion of Lebesgue number, which will be discussed a little later. Another crucial property of compactness is that it is preserved under continuity.

Proposition 37.31. *Let E be a topological space and let F be a topological Hausdorff space. For every compact subset, A , of E , for every continuous map, $f: E \rightarrow F$, the subspace $f(A)$ is compact.*

Proof. Let $(U_i)_{i \in I}$ be an open cover of $f(A)$. We claim that $(f^{-1}(U_i))_{i \in I}$ is an open cover of A , which is easily checked. Since A is compact, there is a finite open subcover, $(f^{-1}(U_j))_{j \in J}$, of A , and thus, $(U_j)_{j \in J}$ is an open subcover of $f(A)$. \square

As a corollary of Proposition 37.31, if E is compact, F is Hausdorff, and $f: E \rightarrow F$ is continuous and bijective, then f is a homeomorphism. Indeed, it is enough to show that f^{-1} is continuous, which is equivalent to showing that f maps closed sets to closed sets. However, closed sets are compact and Proposition 37.31 shows that compact sets are mapped to compact sets, which, by Proposition 37.26, are closed.

Another important corollary of Proposition 37.31 is the following result.

Proposition 37.32. *If E is a compact nonempty topological space and if $f: E \rightarrow \mathbb{R}$ is a continuous function, then there are points $a, b \in E$ such that $f(a)$ is the minimum of $f(E)$ and $f(b)$ is the maximum of $f(E)$.*

Proof. The set $f(E)$ is a compact subset of \mathbb{R} and thus, a closed and bounded set which contains its greatest lower bound and its least upper bound. \square

The following property also holds.

Proposition 37.33. *Let (E, d) be a metric space. For any nonempty subset A of E , if A is compact, then for every open subset U such that $A \subseteq U$, there is some $r > 0$ such that $V_r(A) \subseteq U$.*

Proof. The function $x \mapsto d(x, E - U)$ is continuous and $d(x, E - U) > 0$ for $x \in A$ (since $A \subseteq U$). By Proposition 37.32, there is some $a \in A$ such that

$$d(a, E - U) = \inf_{x \in A} d(x, E - U).$$

But $d(a, E - U) = r > 0$, which implies that $V_r(A) \subseteq U$. \square

Another useful notion is that of local compactness. Indeed manifolds and surfaces are locally compact.

Definition 37.31. A topological space E is *locally compact* if it is Hausdorff and for every $a \in E$, there is some compact neighborhood K of a . See Figure 37.33.

From Proposition 37.30, every compact space is locally compact but the converse is false. For example, \mathbb{R} is locally compact but not compact. In fact it can be shown that a normed vector space of finite dimension is locally compact.

Proposition 37.34. *Given a locally compact topological space, E , for every $a \in E$, for every neighborhood, N , of a , there exists a compact neighborhood, U , of a , such that $U \subseteq N$.*

Proof. For any $a \in E$, there is some compact neighborhood, V , of a . By Proposition 37.30, every neighborhood of a relative to V contains some compact neighborhood U of a relative to V . But every neighborhood of a relative to V is a neighborhood of a relative to E and every neighborhood N of a in E yields a neighborhood, $V \cap N$, of a in V and thus, for every neighborhood, N , of a , there exists a compact neighborhood, U , of a such that $U \subseteq N$. \square

When E is a metric space, the subsets $V_r(A)$ defined in Definition 37.6 have the following property.

Proposition 37.35. *Let (E, d) be a metric space. If E is locally compact, then for any nonempty compact subset A of E , there is some $r > 0$ such that $\overline{V_r(A)}$ is compact.*

Proof. Since E is locally compact, for every $x \in A$, there is some compact subset V_x whose interior $\overset{\circ}{V}_x$ contains x . The family of open subsets $\overset{\circ}{V}_x$ is an open cover A , and since A is compact, it has a finite subcover $\{\overset{\circ}{V}_{x_1}, \dots, \overset{\circ}{V}_{x_n}\}$. Then $U = V_{x_1} \cup \dots \cup V_{x_n}$ is compact (as a finite union of compact subsets), and it contains an open subset containing A (the union of the $\overset{\circ}{V}_{x_i}$). By Proposition 37.33, there is some $r > 0$ such that $V_r(A) \subseteq \overset{\circ}{U}$, and thus $\overline{V_r(A)} \subseteq U$. Since U is compact and $\overline{V_r(A)}$ is closed, $\overline{V_r(A)}$ is compact. \square

It is much harder to deal with noncompact manifolds than it is to deal with compact manifolds. However, manifolds are locally compact and it turns out that there are various ways of embedding a locally compact Hausdorff space into a compact Hausdorff space. The most economical construction consists in adding just one point. This construction, known as the *Alexandroff compactification*, is technically useful, and we now describe it and sketch the proof that it achieves its goal.

To help the reader's intuition, let us consider the case of the plane, \mathbb{R}^2 . If we view the plane, \mathbb{R}^2 , as embedded in 3-space, \mathbb{R}^3 , say as the xy plane of equation $z = 0$, we can consider the sphere, Σ , of radius 1 centered on the z -axis at the point $(0, 0, 1)$ and tangent to the xOy plane at the origin (sphere of equation $x^2 + y^2 + (z - 1)^2 = 1$). If N denotes the north pole on the sphere, i.e., the point of coordinates $(0, 0, 2)$, then any line, D , passing through the north pole and not tangent to the sphere (i.e., not parallel to the xOy plane) intersects the xOy plane in a unique point, M , and the sphere in a unique point, P , other than the north pole, N . This way, we obtain a bijection between the xOy plane and the punctured sphere Σ , i.e., the sphere with the north pole N deleted. This bijection is called a *stereographic projection*. See Figure 37.35.

The Alexandroff compactification of the plane puts the north pole back on the sphere, which amounts to adding a single point at infinity ∞ to the plane. Intuitively, as we travel away from the origin O towards infinity (in any direction!), we tend towards an ideal point at infinity ∞ . Imagine that we "bend" the plane so that it gets wrapped around the sphere,

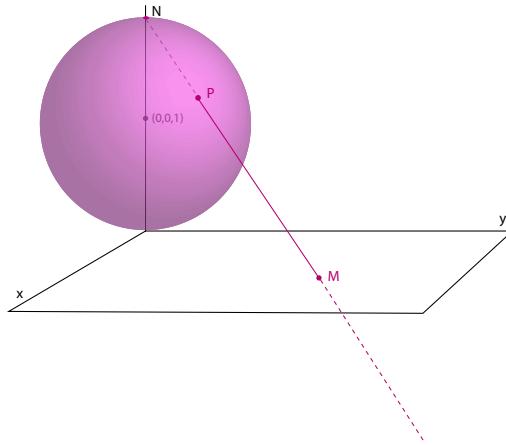

Figure 37.35: The stereographic projections of $x^2 + y^2 + (z - 1)^2 = 1$ onto the xy -plane.

according to stereographic projection. See Figure 37.36. A simpler example takes a line and gets a circle as its compactification. The Alexandroff compactification is a generalization of these simple constructions.

Definition 37.32. Let (E, \mathcal{O}) be a locally compact space. Let ω be any point not in E , and let $E_\omega = E \cup \{\omega\}$. Define the family, \mathcal{O}_ω , as follows:

$$\mathcal{O}_\omega = \mathcal{O} \cup \{(E - K) \cup \{\omega\} \mid K \text{ compact in } E\}.$$

The pair, $(E_\omega, \mathcal{O}_\omega)$, is called the *Alexandroff compactification (or one point compactification) of (E, \mathcal{O})* . See Figure 37.37.

The following theorem shows that $(E_\omega, \mathcal{O}_\omega)$ is indeed a topological space, and that it is compact.

Theorem 37.36. Let E be a locally compact topological space. The Alexandroff compactification, E_ω , of E is a compact space such that E is a subspace of E_ω and if E is not compact, then $\overline{E} = E_\omega$.

Proof. The verification that \mathcal{O}_ω is a family of open sets is not difficult but a bit tedious. Details can be found in Munkres [131] or Schwartz [150]. Let us show that E_ω is compact. For every open cover, $(U_i)_{i \in I}$, of E_ω , since ω must be covered, there is some U_{i_0} of the form

$$U_{i_0} = (E - K_0) \cup \{\omega\}$$

where K_0 is compact in E . Consider the family, $(V_i)_{i \in I}$, defined as follows:

$$\begin{aligned} V_i &= U_i && \text{if } U_i \in \mathcal{O}, \\ V_i &= E - K && \text{if } U_i = (E - K) \cup \{\omega\}, \end{aligned}$$

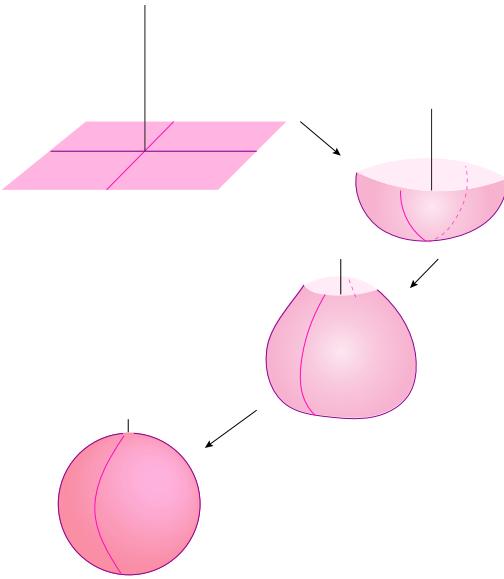

Figure 37.36: A four stage illustration of how the xy -plane is wrapped around the unit sphere centered at $(0, 0, 1)$. When finished all of the sphere is covered except the point $(0, 0, 2)$.

where K is compact in E . Then, because each K is compact and thus closed in E (since E is Hausdorff), $E - K$ is open, and every V_i is an open subset of E . Furthermore, the family, $(V_i)_{i \in (I - \{i_0\})}$, is an open cover of K_0 . Since K_0 is compact, there is a finite open subcover, $(V_j)_{j \in J}$, of K_0 , and thus, $(U_j)_{j \in J \cup \{i_0\}}$ is a finite open cover of E_ω .

Let us show that E_ω is Hausdorff. Given any two points, $a, b \in E_\omega$, if both $a, b \in E$, since E is Hausdorff and every open set in \mathcal{O} is an open set in \mathcal{O}_ω , there exist disjoint open sets, U, V (in \mathcal{O}), such that $a \in U$ and $b \in V$. If $b = \omega$, since E is locally compact, there is some compact set, K , containing an open set, U , containing a and then, U and $V = (E - K) \cup \{\omega\}$ are disjoint open sets (in \mathcal{O}_ω) such that $a \in U$ and $b \in V$.

The space E is a subspace of E_ω because for every open set, U , in \mathcal{O}_ω , either $U \in \mathcal{O}$ and $E \cap U = U$ is open in E , or $U = (E - K) \cup \{\omega\}$, where K is compact in E , and thus, $U \cap E = E - K$, which is open in E , since K is compact in E and thus, closed (since E is Hausdorff). Finally, if E is not compact, for every compact subset, K , of E , $E - K$ is nonempty and thus, for every open set, $U = (E - K) \cup \{\omega\}$, containing ω , we have $U \cap E \neq \emptyset$, which shows that $\omega \in \overline{E}$ and thus, that $\overline{E} = E_\omega$. \square

37.6 Second-Countable and Separable Spaces

In studying surfaces and manifolds, an important property is the existence of a countable basis for the topology. Indeed this property, among other things, guarantees the existence of triangulations of manifolds, and the fact that a manifold is metrizable.

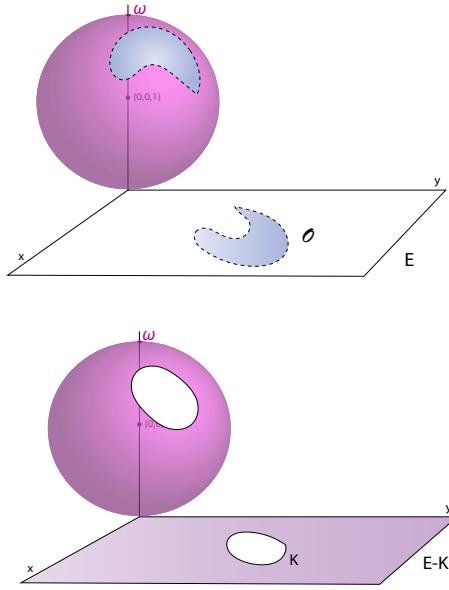

Figure 37.37: The two types of open sets associated with the Alexandroff compactification of the xy -plane. The first type of open set does not include ω , i.e. the north pole, while the second type of open set contains ω .

Definition 37.33. A topological space E is called *second-countable* if there is a countable basis for its topology, i.e., if there is a countable family, $(U_i)_{i \geq 0}$, of open sets such that every open set of E is a union of open sets U_i .

It is easily seen that \mathbb{R}^n is second-countable and more generally, that every normed vector space of finite dimension is second-countable. More generally, a metric space is second-countable if and only if it is separable, a very useful property that holds for all of the spaces that we will consider in practice.

Definition 37.34. A topological space E is *separable* if it contains some countable subset S which is dense in E , that is, $\overline{S} = E$.

Observe that by Proposition 37.4, a subset S of E is dense in E if and only if every nonempty open subset of E contains some element of S .

The (metric) space \mathbb{R} is separable because \mathbb{Q} is a countable dense subset of \mathbb{R} . Similarly, \mathbb{C} is separable. In general, \mathbb{Q}^n is dense in \mathbb{R}^n , so \mathbb{R}^n is separable, and similarly, every finite-dimensional normed vector space over \mathbb{R} (or \mathbb{C}) is separable. For metric spaces, we have the following useful result.

Proposition 37.37. *If E is a metric space, then E is second-countable iff E is separable.*

Proof. If $\mathcal{B} = (B_n)$ is a countable basis for the topology of E , then for any set S obtained by picking some point s_n in B_n , since every nonempty open subset U of E is the union of some of the B_n , the intersection $U \cap S$ is nonempty, and so S is dense in E .

Conversely, assume that there is a countable subset $S = (s_n)$ of E which is dense in E . We claim that the countable family \mathcal{B} of open balls $B_0(s_n, 1/m)$ ($m \in \mathbb{N}, m > 0$) is a basis for the topology of E . For every $x \in E$ and every $r > 0$, there is some $m > 0$ such that $1/m < r/2$, and some n such that $s_n \in B_0(x, 1/m)$. It follows that $x \in B_0(s_n, 1/m)$. For all $y \in B_0(s_n, 1/m)$, we have

$$d(x, y) \leq d(x, s_n) + d(s_n, y) \leq 2/m < r,$$

thus $B_0(s_n, 1/m) \subseteq B_0(x, r)$, which by Proposition 37.8(a) implies that \mathcal{B} is a basis for the topology of E . \square

Proposition 37.38. *If E is a compact metric space, then E is separable.*

Proof. For every $n > 0$, the family of open balls of radius $1/n$ forms an open cover of E , and since E is compact, there is a finite subset A_n of E such that $E = \bigcup_{a_i \in A_n} B_0(a_i, 1/n)$. It is easy to see that this is equivalent to the condition $d(x, A_n) < 1/n$ for all $x \in E$. Let $A = \bigcup_{n \geq 1} A_n$. Then A is countable, and for every $x \in E$, we have

$$d(x, A) \leq d(x, A_n) < \frac{1}{n}, \quad \text{for all } n \geq 1,$$

which implies that $d(x, A) = 0$; that is, A is dense in E . \square

The following theorem due to Uryshon gives a very useful sufficient condition for a topological space to be metrizable.

Theorem 37.39. *(Urysohn metrization theorem) If a topological space E is regular and second-countable, then it is metrizable.*

The proof of Theorem 37.39 can be found in Munkres [131] (Chapter 4, Theorem 34.1). As a corollary of Theorem 37.39, every (second-countable) manifold, and thus every Lie group, is metrizable.

The following technical result shows that a locally compact metrizable space which is also separable can be expressed as the union of a countable monotonic sequence of compact subsets. This gives us a method for generalizing various properties of compact metric spaces to locally compact metric spaces of the above kind.

Proposition 37.40. *Let E be a locally compact metric space. The following properties are equivalent:*

- (1) *There is a sequence $(U_n)_{n \geq 0}$ of open subsets such that for all $n \in \mathbb{N}$, $U_n \subseteq U_{n+1}$, $\overline{U_n}$ is compact, $\overline{U_n} \subseteq U_{n+1}$, and $E = \bigcup_{n \geq 0} U_n = \bigcup_{n \geq 0} \overline{U_n}$.*

(2) *The space E is the union of a countable family of compact subsets of E .*

(3) *The space E is separable.*

Proof. We show (1) implies (2), (2) implies (3), and (3) implies (1). Obviously, (1) implies (2) since the $\overline{U_n}$ are compact.

If (2) holds, then $E = \bigcup_{n \geq 0} K_n$, for some compact subsets K_n . By Proposition 37.38, each compact subset K_n is separable, so let S_n be a countable dense subset of K_n . Then $S = \bigcup_{n \geq 0} S_n$ is a countable dense subset of E , since

$$E = \bigcup_{n \geq 0} K_n \subseteq \bigcup_{n \geq 0} \overline{S_n} \subseteq \overline{S} \subseteq E.$$

Consequently (3) holds.

If (3) holds, let $S = \{s_n\}$ be a countable dense subset of E . By Proposition 37.37, the space E has a countable basis \mathcal{B} of open sets O_n . Since E is locally compact, for every $x \in E$, there is some compact neighborhood W_x containing x , and by Proposition 37.8, there is some index $n(x)$ such that $x \in O_{n(x)} \subseteq W_x$. Since W_x is a compact neighborhood, we deduce that $\overline{O_{n(x)}}$ is compact. Consequently, there is a subfamily of \mathcal{B} consisting of open subsets O_i such that $\overline{O_i}$ is compact, which is a countable basis for the topology of E , so we may assume that we restrict our attention to this basis. We define the sequence $(U_n)_{n \geq 1}$ of open subsets of E by induction as follows: Set $U_1 = O_1$, and let

$$U_{n+1} = O_{n+1} \cup V_r(\overline{U_n}),$$

where $r > 0$ is chosen so that $\overline{V_r(\overline{U_n})}$ is compact, which is possible by Proposition 37.35. We immediately check that the U_n satisfy (1) of Proposition 37.40. \square

It can also be shown that if E is a locally compact space that has a countable basis, then E_ω also has a countable basis (and in fact, is metrizable).

We also have the following property.

Proposition 37.41. *Given a second-countable topological space E , every open cover $(U_i)_{i \in I}$ of E contains some countable subcover.*

Proof. Let $(O_n)_{n \geq 0}$ be a countable basis for the topology. Then all sets O_n contained in some U_i can be arranged into a countable subsequence, $(\Omega_m)_{m \geq 0}$, of $(O_n)_{n \geq 0}$ and for every Ω_m , there is some U_{i_m} such that $\Omega_m \subseteq U_{i_m}$. Furthermore, every U_i is some union of sets Ω_j , and thus, every $a \in E$ belongs to some Ω_j , which shows that $(\Omega_m)_{m \geq 0}$ is a countable open subcover of $(U_i)_{i \in I}$. \square

As an immediate corollary of Proposition 37.41, a locally connected second-countable space has countably many connected components.

37.7 Sequential Compactness

For a general topological Hausdorff space E , the definition of compactness relies on the existence of finite cover. However, when E has a countable basis or is a metric space, we may define the notion of compactness in terms of sequences. To understand how this is done, we need to first define accumulation points.

Definition 37.35. Given a topological Hausdorff space, E , given any sequence, (x_n) , of points in E , a point, $l \in E$, is an *accumulation point* (or *cluster point*) of the sequence (x_n) if every open set, U , containing l contains x_n for infinitely many n . See Figure 37.38.

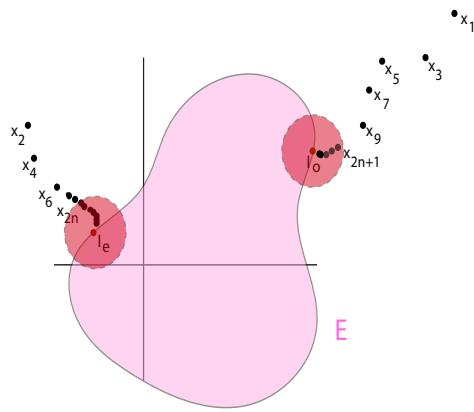

Figure 37.38: The space E is the closed, bounded pink subset of \mathbb{R}^2 . The sequence (x_n) has two accumulation points, one for the subsequence (x_{2n+1}) and one for (x_{2n}) .

Clearly, if l is a limit of the sequence, (x_n) , then it is an accumulation point, since every open set, U , containing a contains all x_n except for finitely many n .

For second-countable spaces we are able to give another characterization of accumulation points.

Proposition 37.42. *Given a second-countable topological Hausdorff space, E , a point, l , is an accumulation point of the sequence, (x_n) , iff l is the limit of some subsequence, (x_{n_k}) , of (x_n) .*

Proof. Clearly, if l is the limit of some subsequence (x_{n_k}) of (x_n) , it is an accumulation point of (x_n) .

Conversely, let $(U_k)_{k \geq 0}$ be the sequence of open sets containing l , where each U_k belongs to a countable basis of E , and let $V_k = U_1 \cap \dots \cap U_k$. For every $k \geq 1$, we can find some $n_k > n_{k-1}$ such that $x_{n_k} \in V_k$, since l is an accumulation point of (x_n) . Now, since every open set containing l contains some U_{k_0} and since $x_{n_k} \in U_{k_0}$ for all $k \geq 0$, the sequence (x_{n_k}) has limit l . \square

Remark: Proposition 37.42 also holds for metric spaces.

As an illustration of Proposition 37.42 let (x_n) be the sequence $(1, -1, 1, -1, \dots)$. This sequence has two accumulation points, namely 1 and -1 since $(x_{2n+1}) = (1)$ and $(x_{2n}) = (-1)$.

In second-countable Hausdorff spaces, compactness can be characterized in terms of accumulation points (this is also true for metric spaces).

Proposition 37.43. *A second-countable topological Hausdorff space, E , is compact iff every sequence, (x_n) , of E has some accumulation point in E .*

Proof. Assume that every sequence, (x_n) , has some accumulation point. Let $(U_i)_{i \in I}$ be some open cover of E . By Proposition 37.41, there is a countable open subcover, $(O_n)_{n \geq 0}$, for E . Now, if E is not covered by any finite subcover of $(O_n)_{n \geq 0}$, we can define a sequence, (x_m) , by induction as follows:

Let x_0 be arbitrary and for every $m \geq 1$, let x_m be some point in E not in $O_1 \cup \dots \cup O_m$, which exists, since $O_1 \cup \dots \cup O_m$ is not an open cover of E . We claim that the sequence, (x_m) , does not have any accumulation point. Indeed, for every $l \in E$, since $(O_n)_{n \geq 0}$ is an open cover of E , there is some O_m such that $l \in O_m$, and by construction, every x_n with $n \geq m + 1$ does not belong to O_m , which means that $x_n \in O_m$ for only finitely many n and l is not an accumulation point. See Figure 37.39.

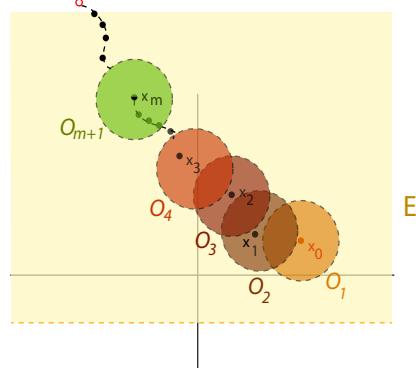

Figure 37.39: The space E is the open half plane above the line $y = -1$. Since E is not compact, we inductively build a sequence, (x_n) that will have no accumulation point in E . Note the y coordinate of x_n approaches infinity.

Conversely, assume that E is compact, and let (x_n) be any sequence. If $l \in E$ is not an accumulation point of the sequence, then there is some open set, U_l , such that $l \in U_l$

and $x_n \in U_l$ for only finitely many n . Thus, if (x_n) does not have any accumulation point, the family, $(U_l)_{l \in E}$, is an open cover of E and since E is compact, it has some finite open subcover, $(U_l)_{l \in J}$, where J is a finite subset of E . But every U_l with $l \in J$ is such that $x_n \in U_l$ for only finitely many n , and since J is finite, $x_n \in \bigcup_{l \in J} U_l$ for only finitely many n , which contradicts the fact that $(U_l)_{l \in J}$ is an open cover of E , and thus contains all the x_n . Thus, (x_n) has some accumulation point. See Figure 37.40. \square

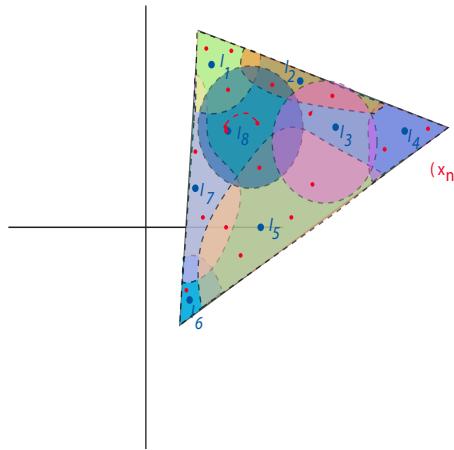

Figure 37.40: The space E the closed triangular region of \mathbb{R}^2 . Given a sequence (x_n) of red points in E , if the sequence has no accumulation points, then each l_i for $1 \leq i \leq 8$, is not an accumulation point. But as implied by the illustration, l_8 actually is an accumulation point of (x_n) .

Remarks:

1. By combining Propositions 37.42 and 37.43, we have observe that a second-countable Hausdorff space E is compact iff every sequence (x_n) has a convergent subsequence (x_{n_k}) . In other words, we say a second-countable Hausdorff space E is compact iff it is *sequentially compact*.
2. It should be noted that the proof showing that if E is compact, then every sequence has some accumulation point, holds for any arbitrary compact space (the proof does not use a countable basis for the topology). The converse also holds for metric spaces. We will prove this converse since it is a major property of metric spaces.

Given a metric space in which every sequence has some accumulation point, we first prove the existence of a *Lebesgue number*.

Lemma 37.44. *Given a metric space, E , if every sequence, (x_n) , has an accumulation point, for every open cover, $(U_i)_{i \in I}$, of E , there is some $\delta > 0$ (a Lebesgue number for $(U_i)_{i \in I}$) such that, for every open ball, $B_0(a, \epsilon)$, of radius $\epsilon \leq \delta$, there is some open subset, U_i , such that $B_0(a, \epsilon) \subseteq U_i$. See Figure 37.41*

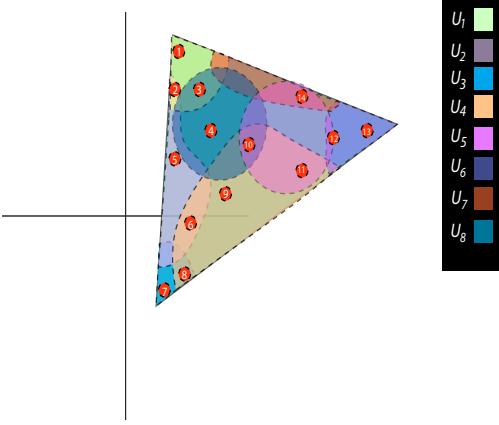

Figure 37.41: The space E the closed triangular region of \mathbb{R}^2 . Its open cover is $(U_i)_{i=1}^8$. The Lebesgue number is the radius of the small orange balls labelled 1 through 14. Each open ball of this radius entirely contained within at least one U_i . For example, Ball 2 is contained in both U_1 and U_2 .

Proof. If there was no δ with the above property, then, for every natural number, n , there would be some open ball, $B_0(a_n, 1/n)$, which is not contained in any open set, U_i , of the open cover, $(U_i)_{i \in I}$. However, the sequence, (a_n) , has some accumulation point, a , and since $(U_i)_{i \in I}$ is an open cover of E , there is some U_i such that $a \in U_i$. Since U_i is open, there is some open ball of center a and radius ϵ contained in U_i . Now, since a is an accumulation point of the sequence, (a_n) , every open set containing a contains a_n for infinitely many n and thus, there is some n large enough so that

$$1/n \leq \epsilon/2 \quad \text{and} \quad a_n \in B_0(a, \epsilon/2),$$

which implies that

$$B_0(a_n, 1/n) \subseteq B_0(a, \epsilon) \subseteq U_i,$$

a contradiction. \square

By a previous remark, since the proof of Proposition 37.43 implies that in a compact topological space, every sequence has some accumulation point, by Lemma 37.44, in a compact metric space, every open cover has a Lebesgue number. This fact can be used to prove another important property of compact metric spaces, the uniform continuity theorem.

Definition 37.36. Given two metric spaces, (E, d_E) and (F, d_F) , a function, $f: E \rightarrow F$, is *uniformly continuous* if for every $\epsilon > 0$, there is some $\eta > 0$, such that, for all $a, b \in E$,

$$\text{if } d_E(a, b) \leq \eta \text{ then } d_F(f(a), f(b)) \leq \epsilon.$$

See Figures 37.42 and 37.43.

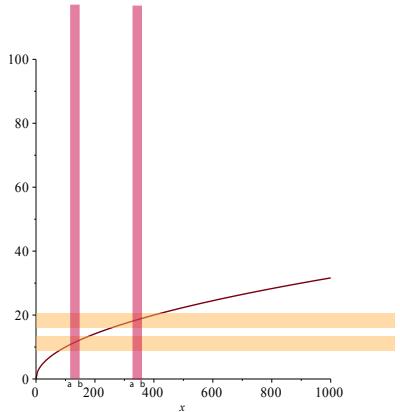

Figure 37.42: The real valued function $f(x) = \sqrt{x}$ is uniformly continuous over $(0, \infty)$. Fix ϵ . If the x values lie within the rose colored η strip, the y values always lie within the peach ϵ strip.

As we saw earlier, the metric on a metric space is uniformly continuous, and the norm on a normed metric space is uniformly continuous.

The *uniform continuity theorem* can be stated as follows:

Theorem 37.45. *Given two metric spaces, (E, d_E) and (F, d_F) , if E is compact and if $f: E \rightarrow F$ is a continuous function, then f is uniformly continuous.*

Proof. Consider any $\epsilon > 0$ and let $(B_0(y, \epsilon/2))_{y \in F}$ be the open cover of F consisting of open balls of radius $\epsilon/2$. Since f is continuous, the family,

$$(f^{-1}(B_0(y, \epsilon/2)))_{y \in F},$$

is an open cover of E . Since, E is compact, by Lemma 37.44, there is a Lebesgue number, δ , such that for every open ball, $B_0(a, \eta)$, of radius $\eta \leq \delta$, then $B_0(a, \eta) \subseteq f^{-1}(B_0(y, \epsilon/2))$, for some $y \in F$. In particular, for any $a, b \in E$ such that $d_E(a, b) \leq \eta = \delta/2$, we have $a, b \in B_0(a, \delta)$ and thus, $a, b \in f^{-1}(B_0(y, \epsilon/2))$, which implies that $f(a), f(b) \in B_0(y, \epsilon/2)$. But then, $d_F(f(a), f(b)) \leq \epsilon$, as desired. \square

We now prove another lemma needed to obtain the characterization of compactness in metric spaces in terms of accumulation points.

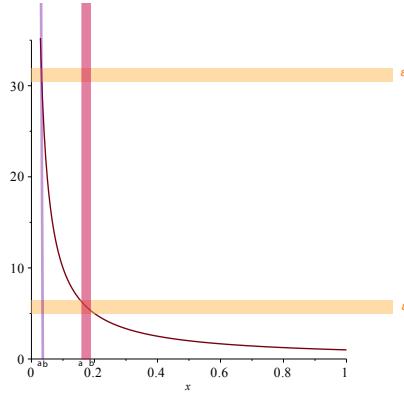

Figure 37.43: The real valued function $f(x) = 1/x$ is not uniformly continuous over $(0, \infty)$. Fix ϵ . In order for the y values to lie within the peach epsilon strip, the widths of the eta strips decrease as $x \rightarrow 0$.

Lemma 37.46. *Given a metric space, E , if every sequence, (x_n) , has an accumulation point, then for every $\epsilon > 0$, there is a finite open cover, $B_0(a_0, \epsilon) \cup \dots \cup B_0(a_n, \epsilon)$, of E by open balls of radius ϵ .*

Proof. Let a_0 be any point in E . If $B_0(a_0, \epsilon) = E$, then the lemma is proved. Otherwise, assume that a sequence, (a_0, a_1, \dots, a_n) , has been defined, such that $B_0(a_0, \epsilon) \cup \dots \cup B_0(a_n, \epsilon)$ does not cover E . Then, there is some a_{n+1} not in $B_0(a_0, \epsilon) \cup \dots \cup B_0(a_n, \epsilon)$ and either

$$B_0(a_0, \epsilon) \cup \dots \cup B_0(a_{n+1}, \epsilon) = E,$$

in which case the lemma is proved, or we obtain a sequence, $(a_0, a_1, \dots, a_{n+1})$, such that $B_0(a_0, \epsilon) \cup \dots \cup B_0(a_{n+1}, \epsilon)$ does not cover E . If this process goes on forever, we obtain an infinite sequence, (a_n) , such that $d(a_m, a_n) > \epsilon$ for all $m \neq n$. Since every sequence in E has some accumulation point, the sequence, (a_n) , has some accumulation point, a . Then, for infinitely many n , we must have $d(a_n, a) \leq \epsilon/3$ and thus, for at least two distinct natural numbers, p, q , we must have $d(a_p, a) \leq \epsilon/3$ and $d(a_q, a) \leq \epsilon/3$, which implies $d(a_p, a_q) \leq d(a_p, a) + d(a_q, a) \leq 2\epsilon/3$, contradicting the fact that $d(a_m, a_n) > \epsilon$ for all $m \neq n$. See Figure 37.44. Thus, there must be some n such that

$$B_0(a_0, \epsilon) \cup \dots \cup B_0(a_n, \epsilon) = E. \quad \square$$

Definition 37.37. A metric space E is said to be *precompact* (or *totally bounded*) if for every $\epsilon > 0$, there is a finite open cover, $B_0(a_0, \epsilon) \cup \dots \cup B_0(a_n, \epsilon)$, of E by open balls of radius ϵ .

We now obtain the *Weierstrass–Bolzano* property.

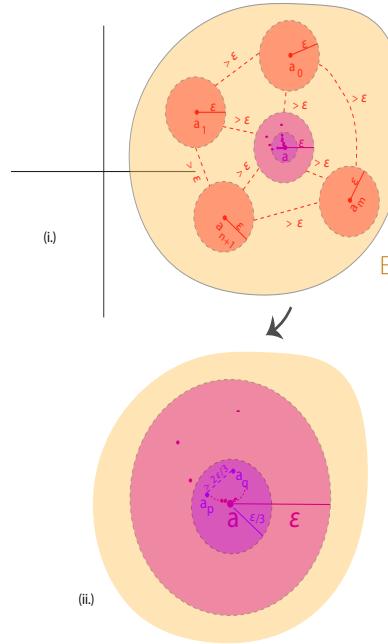

Figure 37.44: Let E be the peach region of \mathbb{R}^2 . If E is not covered by a finite collection of orange balls with radius ϵ , the points of the sequence (a_n) are separated by a distance of at least ϵ . This contradicts the fact that a is the accumulation point of a , as evidenced by the enlargement of the plum disk in Figure (ii).

Theorem 37.47. *A metric space, E , is compact iff every sequence, (x_n) , has an accumulation point.*

Proof. We already observed that the proof of Proposition 37.43 shows that for any compact space (not necessarily metric), every sequence, (x_n) , has an accumulation point. Conversely, let E be a metric space, and assume that every sequence, (x_n) , has an accumulation point. Given any open cover, $(U_i)_{i \in I}$ for E , we must find a finite open subcover of E . By Lemma 37.44, there is some $\delta > 0$ (a Lebesgue number for $(U_i)_{i \in I}$) such that, for every open ball, $B_0(a, \epsilon)$, of radius $\epsilon \leq \delta$, there is some open subset, U_j , such that $B_0(a, \epsilon) \subseteq U_j$. By Lemma 37.46, for every $\delta > 0$, there is a finite open cover, $B_0(a_0, \delta) \cup \dots \cup B_0(a_n, \delta)$, of E by open balls of radius δ . But from the previous statement, every open ball, $B_0(a_i, \delta)$, is contained in some open set, U_{j_i} , and thus, $\{U_{j_1}, \dots, U_{j_n}\}$ is an open cover of E . \square

37.8 Complete Metric Spaces and Compactness

Another very useful characterization of compact metric spaces is obtained in terms of Cauchy sequences. Such a characterization is quite useful in fractal geometry (and elsewhere). First

recall the definition of a Cauchy sequence and of a complete metric space.

Definition 37.38. Given a metric space, (E, d) , a sequence, $(x_n)_{n \in \mathbb{N}}$, in E is a *Cauchy sequence* if the following condition holds: for every $\epsilon > 0$, there is some $p \geq 0$, such that, for all $m, n \geq p$, then $d(x_m, x_n) \leq \epsilon$.

If every Cauchy sequence in (E, d) converges we say that (E, d) is a *complete metric space*.

First let us show the following proposition:

Proposition 37.48. *Given a metric space, E , if a Cauchy sequence, (x_n) , has some accumulation point, a , then a is the limit of the sequence, (x_n) .*

Proof. Since (x_n) is a Cauchy sequence, for every $\epsilon > 0$, there is some $p \geq 0$, such that, for all $m, n \geq p$, then $d(x_m, x_n) \leq \epsilon/2$. Since a is an accumulation point for (x_n) , for infinitely many n , we have $d(x_n, a) \leq \epsilon/2$, and thus, for at least some $n \geq p$, we have $d(x_n, a) \leq \epsilon/2$. Then, for all $m \geq p$,

$$d(x_m, a) \leq d(x_m, x_n) + d(x_n, a) \leq \epsilon,$$

which shows that a is the limit of the sequence (x_n) . \square

We can now prove the following theorem.

Theorem 37.49. *A metric space, E , is compact iff it is precompact and complete.*

Proof. Let E be compact. For every $\epsilon > 0$, the family of all open balls of radius ϵ is an open cover for E and since E is compact, there is a finite subcover, $B_0(a_0, \epsilon) \cup \dots \cup B_0(a_n, \epsilon)$, of E by open balls of radius ϵ . Thus E is precompact. Since E is compact, by Theorem 37.47, every sequence, (x_n) , has some accumulation point. Thus every Cauchy sequence, (x_n) , has some accumulation point, a , and, by Proposition 37.48, a is the limit of (x_n) . Thus, E is complete.

Now assume that E is precompact and complete. We prove that every sequence, (x_n) , has an accumulation point. By the other direction of Theorem 37.47, this shows that E is compact. Given any sequence, (x_n) , we construct a Cauchy subsequence, (y_n) , of (x_n) as follows: Since E is precompact, letting $\epsilon = 1$, there exists a finite cover, \mathcal{U}_1 , of E by open balls of radius 1. Thus some open ball, B_o^0 , in the cover, \mathcal{U}_1 , contains infinitely many elements from the sequence (x_n) . Let y_0 be any element of (x_n) in B_o^0 . By induction, assume that a sequence of open balls, $(B_o^i)_{1 \leq i \leq m}$, has been defined, such that every ball, B_o^i , has radius $\frac{1}{2^i}$, contains infinitely many elements from the sequence (x_n) and contains some y_i from (x_n) such that

$$d(y_i, y_{i+1}) \leq \frac{1}{2^i},$$

for all i , $0 \leq i \leq m - 1$. See Figure 37.45. Then letting $\epsilon = \frac{1}{2^{m+1}}$, because E is precompact, there is some finite cover, \mathcal{U}_{m+1} , of E by open balls of radius ϵ and thus, of the open ball B_o^m .

Thus, some open ball, B_o^{m+1} , in the cover, \mathcal{U}_{m+1} , contains infinitely many elements from the sequence, (x_n) , and we let y_{m+1} be any element of (x_n) in B_o^{m+1} . Thus, we have defined by induction a sequence, (y_n) , which is a subsequence of, (x_n) , and such that

$$d(y_i, y_{i+1}) \leq \frac{1}{2^i},$$

for all i . However, for all $m, n \geq 1$, we have

$$d(y_m, y_n) \leq d(y_m, y_{m+1}) + \cdots + d(y_{n-1}, y_n) \leq \sum_{i=m}^n \frac{1}{2^i} \leq \frac{1}{2^{m-1}},$$

and thus, (y_n) is a Cauchy sequence Since E is complete, the sequence, (y_n) , has a limit, and since it is a subsequence of (x_n) , the sequence, (x_n) , has some accumulation point. \square

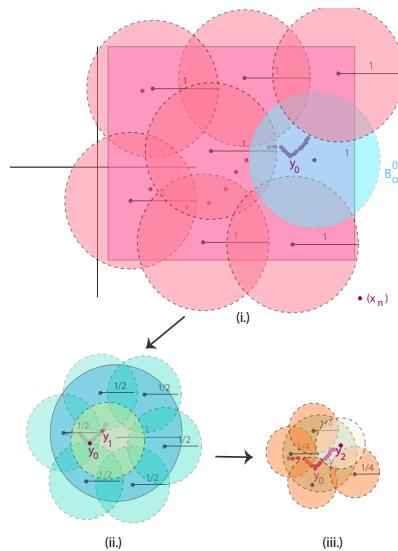

Figure 37.45: The first three stages of the construction of the Cauchy sequence (y_n) , where E is the pink square region of \mathbb{R}^2 . The original sequence (x_n) is illustrated with plum colored dots. Figure (i.) covers E with ball of radius 1 and shows the selection of B_o^0 and y_0 . Figure (ii.) covers B_o^0 with balls of radius $1/2$ and selects the yellow ball as B_o^1 with point y_1 . Figure (iii.) covers B_o^1 with balls of radius $1/4$ and selects the pale peach ball as B_o^2 with point y_2 .

Another useful property of a complete metric space is that a subset is closed iff it is complete. This is shown in the following two propositions.

Proposition 37.50. *Let (E, d) be a metric space, and let A be a subset of E . If A is complete (which means that every Cauchy sequence of elements in A converges to some point of A), then A is closed in E .*

Proof. Assume $x \in \overline{A}$. By Proposition 37.13, there is some sequence (a_n) of points $a_n \in A$ which converges to x . Consequently (a_n) is a Cauchy sequence in E , and thus a Cauchy sequence in A (since $a_n \in A$ for all n). Since A is complete, the sequence (a_n) has a limit $a \in A$, but since E is a metric space it is Hausdorff, so $a = x$, which shows that $x \in A$; that is, A is closed. \square

Proposition 37.51. *Let (E, d) be a metric space, and let A be a subset of E . If E is complete and if A is closed in E , then A is complete.*

Proof. Let (a_n) be a Cauchy sequence in A . The sequence (a_n) is also a Cauchy sequence in E , and since E is complete, it has a limit $x \in E$. But $a_n \in A$ for all n , so by Proposition 37.13 we must have $x \in \overline{A}$. Since A is closed, actually $x \in A$, which proves that A is complete. \square

An arbitrary metric space (E, d) is not necessarily complete, but there is a construction of a metric space $(\widehat{E}, \widehat{d})$ such that \widehat{E} is complete, and there is a continuous (injective) distance-preserving map $\varphi: E \rightarrow \widehat{E}$ such that $\varphi(E)$ is dense in \widehat{E} . This is a generalization of the construction of the set \mathbb{R} of real numbers from the set \mathbb{Q} of rational numbers in terms of Cauchy sequences. This construction can be immediately adapted to a normed vector space $(E, \| \cdot \|)$ to embed $(E, \| \cdot \|)$ into a complete normed vector space $(\widehat{E}, \| \cdot \|_{\widehat{E}})$ (a Banach space). This construction is used heavily in integration theory, where E is a set of functions.

37.9 Completion of a Metric Space

In order to prove a kind of uniqueness result for the completion $(\widehat{E}, \widehat{d})$ of a metric space (E, d) , we need the following result about extending a uniformly continuous function.

Recall that E_0 is dense in E iff $\overline{E_0} = E$. Since E is a metric space, by Proposition 37.13, this means that for every $x \in E$, there is some sequence (x_n) converging to x , with $x_n \in E_0$.

Theorem 37.52. *Let E and F be two metric spaces, let E_0 be a dense subspace of E , and let $f_0: E_0 \rightarrow F$ be a continuous function. If f_0 is uniformly continuous and if F is complete, then there is a unique uniformly continuous function $f: E \rightarrow F$ extending f_0 .*

Proof. We follow Schwartz's proof; see Schwartz [149] (Chapter XI, Section 3, Theorem 1).

Step 1. We begin by constructing a function $f: E \rightarrow F$ extending f_0 . Since E_0 is dense in E , for every $x \in E$, there is some sequence (x_n) converging to x , with $x_n \in E_0$. Then the sequence (x_n) is a Cauchy sequence in E . We claim that $(f_0(x_n))$ is a Cauchy sequence in F .

Proof of the claim. For every $\epsilon > 0$, since f_0 is uniformly continuous, there is some $\eta > 0$ such that for all $(y, z) \in E_0$, if $d(y, z) \leq \eta$, then $d(f_0(y), f_0(z)) \leq \epsilon$. Since (x_n) is a Cauchy sequence with $x_n \in E_0$, there is some integer $p > 0$ such that if $m, n \geq p$, then $d(x_m, x_n) \leq \eta$, thus $d(f_0(x_m), f_0(x_n)) \leq \epsilon$, which proves that $(f_0(x_n))$ is a Cauchy sequence in F . \square

Since F is complete and $(f_0(x_n))$ is a Cauchy sequence in F , the sequence $(f_0(x_n))$ converges to some element of F ; denote this element by $f(x)$.

Step 2. Let us now show that $f(x)$ does not depend on the sequence (x_n) converging to x . Suppose that (x'_n) and (x''_n) are two sequences of elements in E_0 converging to x . Then the mixed sequence

$$x'_0, x''_0, x'_1, x''_1, \dots, x'_n, x''_n, \dots,$$

also converges to x . It follows that the sequence

$$f_0(x'_0), f_0(x''_0), f_0(x'_1), f_0(x''_1), \dots, f_0(x'_n), f_0(x''_n), \dots,$$

is a Cauchy sequence in F , and since F is complete, it converges to some element of F , which implies that the sequences $(f_0(x'_n))$ and $(f_0(x''_n))$ converge to the same limit.

As a summary, we have defined a function $f: E \rightarrow F$ by

$$f(x) = \lim_{n \rightarrow \infty} f_0(x_n).$$

for any sequence (x_n) converging to x , with $x_n \in E_0$.

Step 3. The function f extends f_0 . Since every element $x \in E_0$ is the limit of the constant sequence (x_n) with $x_n = x$ for all $n \geq 0$, by definition $f(x)$ is the limit of the sequence $(f_0(x_n))$, which is the constant sequence with value $f_0(x)$, so $f(x) = f_0(x)$; that is, f extends f_0 .

Step 4. We now prove that f is uniformly continuous. Since f_0 is uniformly continuous, for every $\epsilon > 0$, there is some $\eta > 0$ such that if $a, b \in E_0$ and $d(a, b) \leq \eta$, then $d(f_0(a), f_0(b)) \leq \epsilon$. Consider any two points $x, y \in E$ such that $d(x, y) \leq \eta/2$. We claim that $d(f(x), f(y)) \leq \epsilon$, which shows that f is uniformly continuous.

Let (x_n) be a sequence of points in E_0 converging to x , and let (y_n) be a sequence of points in E_0 converging to y . By the triangle inequality,

$$d(x_n, y_n) \leq d(x_n, x) + d(x, y) + d(y, y_n) = d(x, y) + d(x_n, x) + d(y_n, y),$$

and since (x_n) converges to x and (y_n) converges to y , there is some integer $p > 0$ such that for all $n \geq p$, we have $d(x_n, x) \leq \eta/4$ and $d(y_n, y) \leq \eta/4$, and thus

$$d(x_n, y_n) \leq d(x, y) + \frac{\eta}{2}.$$

Since we assumed that $d(x, y) \leq \eta/2$, we get $d(x_n, y_n) \leq \eta$ for all $n \geq p$, and by uniform continuity of f_0 , we get

$$d(f_0(x_n), f_0(y_n)) \leq \epsilon$$

for all $n \geq p$. Since the distance function on F is also continuous, and since $(f_0(x_n))$ converges to $f(x)$ and $(f_0(y_n))$ converges to $f(y)$, we deduce that the sequence $(d(f_0(x_n), f_0(y_n)))$ converges to $d(f(x), f(y))$. This implies that $d(f(x), f(y)) \leq \epsilon$, as desired.

Step 5. It remains to prove that f is unique. Since E_0 is dense in E , for every $x \in E$, there is some sequence (x_n) converging to x , with $x_n \in E_0$. Since f extends f_0 and since f is continuous, we get

$$f(x) = \lim_{n \rightarrow \infty} f_0(x_n),$$

which only depends on f_0 and x , and shows that f is unique. \square

Remark: It can be shown that the theorem no longer holds if we either omit the hypothesis that F is complete or omit that f_0 is uniformly continuous.

For example, if $E_0 \neq E$ and if we let $F = E_0$ and f_0 be the identity function, it is easy to see that f_0 cannot be extended to a continuous function from E to E_0 (for any $x \in E - E_0$, any continuous extension f of f_0 would satisfy $f(x) = x$, which is absurd since $x \notin E_0$).

If f_0 is continuous but not uniformly continuous, a counter-example can be given by using $E = \overline{\mathbb{R}} = \mathbb{R} \cup \{\infty\}$ made into a metric space, $E_0 = \mathbb{R}$, $F = \mathbb{R}$, and f_0 the identity function; for details, see Schwartz [149] (Chapter XI, Section 3, page 134).

Definition 37.39. If (E, d_E) and (F, d_F) are two metric spaces, then a function $f: E \rightarrow F$ is *distance-preserving*, or an *isometry*, if

$$d_F(f(x), f(y)) = d_E(x, y), \quad \text{for all } x, y \in E.$$

Observe that an isometry must be injective, because if $f(x) = f(y)$, then $d_F(f(x), f(y)) = 0$, and since $d_F(f(x), f(y)) = d_E(x, y)$, we get $d_E(x, y) = 0$, but $d_E(x, y) = 0$ implies that $x = y$. Also, an isometry is uniformly continuous (since we can pick $\eta = \epsilon$ to satisfy the condition of uniform continuity). However, an isometry is not necessarily surjective.

We now give a construction of the completion of a metric space. This construction is just a generalization of the classical construction of \mathbb{R} from \mathbb{Q} using Cauchy sequences.

Theorem 37.53. Let (E, d) be any metric space. There is a complete metric space $(\widehat{E}, \widehat{d})$ called a completion of (E, d) , and a distance-preserving (uniformly continuous) map $\varphi: E \rightarrow \widehat{E}$ such that $\varphi(E)$ is dense in \widehat{E} , and the following extension property holds: for every complete metric space F and for every uniformly continuous function $f: E \rightarrow F$, there is a unique uniformly continuous function $\widehat{f}: \widehat{E} \rightarrow F$ such that

$$f = \widehat{f} \circ \varphi,$$

as illustrated in the following diagram.

$$\begin{array}{ccc} E & \xrightarrow{\varphi} & \widehat{E} \\ & \searrow f & \downarrow \widehat{f} \\ & & F. \end{array}$$

As a consequence, for any two completions $(\widehat{E}_1, \widehat{d}_1)$ and $(\widehat{E}_2, \widehat{d}_2)$ of (E, d) , there is a unique bijective isometry between $(\widehat{E}_1, \widehat{d}_1)$ and $(\widehat{E}_2, \widehat{d}_2)$.

Proof. Consider the set \mathcal{E} of all Cauchy sequences (x_n) in E , and define the relation \sim on \mathcal{E} as follows:

$$(x_n) \sim (y_n) \quad \text{iff} \quad \lim_{n \rightarrow \infty} d(x_n, y_n) = 0.$$

It is easy to check that \sim is an equivalence relation on \mathcal{E} , and let $\widehat{E} = \mathcal{E}/\sim$ be the quotient set, that is, the set of equivalence classes modulo \sim . Our goal is to show that we can endow \widehat{E} with a distance that makes it into a complete metric space satisfying the conditions of the theorem. We proceed in several steps.

Step 1. First, let us construct the function $\varphi: E \rightarrow \widehat{E}$. For every $a \in E$, we have the constant sequence (a_n) such that $a_n = a$ for all $n \geq 0$, which is obviously a Cauchy sequence. Let $\varphi(a) \in \widehat{E}$ be the equivalence class $[(a_n)]$ of the constant sequence (a_n) with $a_n = a$ for all n . By definition of \sim , the equivalence class $\varphi(a)$ is also the equivalence class of all sequences converging to a . The map $a \mapsto \varphi(a)$ is injective because a metric space is Hausdorff, so if $a \neq b$, then a sequence converging to a does not converge to b . After having defined a distance on \widehat{E} , we will check that φ is an isometry.

Step 2. Let us now define a distance on \widehat{E} . Let $\alpha = [(a_n)]$ and $\beta = [(b_n)]$ be two equivalence classes of Cauchy sequences in E . The triangle inequality implies that

$$d(a_m, b_m) \leq d(a_m, a_n) + d(a_n, b_n) + d(b_n, b_m) = d(a_n, b_n) + d(a_m, a_n) + d(b_m, b_n)$$

and

$$d(a_n, b_n) \leq d(a_n, a_m) + d(a_m, b_m) + d(b_m, b_n) = d(a_m, b_m) + d(a_m, a_n) + d(b_m, b_n),$$

which implies that

$$|d(a_m, b_m) - d(a_n, b_n)| \leq d(a_m, a_n) + d(b_m, b_n).$$

Since (a_n) and (b_n) are Cauchy sequences, it follows that $(d(a_n, b_n))$ is a Cauchy sequence of nonnegative reals. Since \mathbb{R} is complete, the sequence $(d(a_n, b_n))$ has a limit, which we denote by $\widehat{d}(\alpha, \beta)$; that is, we set

$$\widehat{d}(\alpha, \beta) = \lim_{n \rightarrow \infty} d(a_n, b_n), \quad \alpha = [(a_n)], \beta = [(b_n)].$$

Step 3. Let us check that $\widehat{d}(\alpha, \beta)$ does not depend on the Cauchy sequences (a_n) and (b_n) chosen in the equivalence classes α and β .

If $(a_n) \sim (a'_n)$ and $(b_n) \sim (b'_n)$, then $\lim_{n \rightarrow \infty} d(a_n, a'_n) = 0$ and $\lim_{n \rightarrow \infty} d(b_n, b'_n) = 0$, and since

$$d(a'_n, b'_n) \leq d(a'_n, a_n) + d(a_n, b_n) + d(b_n, b'_n) = d(a_n, b_n) + d(a_n, a'_n) + d(b_n, b'_n)$$

and

$$d(a_n, b_n) \leq d(a_n, a'_n) + d(a'_n, b'_n) + d(b'_n, b_n) = d(a'_n, b'_n) + d(a_n, a'_n) + d(b_n, b'_n)$$

we have

$$|d(a_n, b_n) - d(a'_n, b'_n)| \leq d(a_n, a'_n) + d(b_n, b'_n),$$

so we have $\lim_{n \rightarrow \infty} d(a'_n, b'_n) = \lim_{n \rightarrow \infty} d(a_n, b_n) = \widehat{d}(\alpha, \beta)$. Therefore, $\widehat{d}(\alpha, \beta)$ is indeed well defined.

Step 4. Let us check that φ is indeed an isometry.

Given any two elements $\varphi(a)$ and $\varphi(b)$ in \widehat{E} , since they are the equivalence classes of the constant sequences (a_n) and (b_n) such that $a_n = a$ and $b_n = b$ for all n , the constant sequence $(d(a_n, b_n))$ with $d(a_n, b_n) = d(a, b)$ for all n converges to $d(a, b)$, so by definition $\widehat{d}(\varphi(a), \varphi(b)) = \lim_{n \rightarrow \infty} d(a_n, b_n) = d(a, b)$, which shows that φ is an isometry.

Step 5. Let us verify that \widehat{d} is a metric on \widehat{E} . By definition it is obvious that $\widehat{d}(\alpha, \beta) = \widehat{d}(\beta, \alpha)$. If α and β are two distinct equivalence classes, then for any Cauchy sequence (a_n) in the equivalence class α and for any Cauchy sequence (b_n) in the equivalence class β , the sequences (a_n) and (b_n) are inequivalent, which means that $\lim_{n \rightarrow \infty} d(a_n, b_n) \neq 0$, that is, $\widehat{d}(\alpha, \beta) \neq 0$. Obviously, $\widehat{d}(\alpha, \alpha) = 0$.

For any equivalence classes $\alpha = [(a_n)]$, $\beta = [(b_n)]$, and $\gamma = [(c_n)]$, we have the triangle inequality

$$d(a_n, c_n) \leq d(a_n, b_n) + d(b_n, c_n),$$

so by continuity of the distance function, by passing to the limit, we obtain

$$\widehat{d}(\alpha, \gamma) \leq \widehat{d}(\alpha, \beta) + \widehat{d}(\beta, \gamma),$$

which is the triangle inequality for \widehat{d} . Therefore, \widehat{d} is a distance on \widehat{E} .

Step 6. Let us prove that $\varphi(E)$ is dense in \widehat{E} . For any $\alpha = [(a_n)]$, let (x_n) be the constant sequence such that $x_k = a_n$ for all $k \geq 0$, so that $\varphi(a_n) = [(x_n)]$. Then we have

$$\widehat{d}(\alpha, \varphi(a_n)) = \lim_{m \rightarrow \infty} d(a_m, a_n) \leq \sup_{p, q \geq n} d(a_p, a_q).$$

Since (a_n) is a Cauchy sequence, $\sup_{p, q \geq n} d(a_p, a_q)$ tends to 0 as n goes to infinity, so

$$\lim_{n \rightarrow \infty} d(\alpha, \varphi(a_n)) = 0,$$

which means that the sequence $(\varphi(a_n))$ converge to α , and $\varphi(E)$ is indeed dense in \widehat{E} .

Step 7. Finally, let us prove that the metric space \widehat{E} is complete.

Let (α_n) be a Cauchy sequence in \widehat{E} . Since $\varphi(E)$ is dense in \widehat{E} , for every $n > 0$, there some $a_n \in E$ such that

$$\widehat{d}(\alpha_n, \varphi(a_n)) \leq \frac{1}{n}.$$

Since

$$\widehat{d}(\varphi(a_m), \varphi(a_n)) \leq \widehat{d}(\varphi(a_m), \alpha_m) + \widehat{d}(\alpha_m, \alpha_n) + \widehat{d}(\alpha_n, \varphi(a_n)) \leq \widehat{d}(\alpha_m, \alpha_n) + \frac{1}{m} + \frac{1}{n},$$

and since (α_m) is a Cauchy sequence, so is $(\varphi(a_n))$, and as φ is an isometry, the sequence (a_n) is a Cauchy sequence in E . Let $\alpha \in \widehat{E}$ be the equivalence class of (a_n) . Since

$$\widehat{d}(\alpha, \varphi(a_n)) = \lim_{m \rightarrow \infty} d(a_m, a_n)$$

and (a_n) is a Cauchy sequence, we deduce that the sequence $(\varphi(a_n))$ converges to α , and since $d(\alpha_n, \varphi(a_n)) \leq 1/n$ for all $n > 0$, the sequence (α_n) also converges to α .

Step 8. Let us prove the extension property. Let F be any complete metric space and let $f: E \rightarrow F$ be any uniformly continuous function. The function $\varphi: E \rightarrow \widehat{E}$ is an isometry and a bijection between E and its image $\varphi(E)$, so its inverse $\varphi^{-1}: \varphi(E) \rightarrow E$ is also an isometry, and thus is uniformly continuous. If we let $g = f \circ \varphi^{-1}$, then $g: \varphi(E) \rightarrow F$ is a uniformly continuous function, and $\varphi(E)$ is dense in \widehat{E} , so by Theorem 37.52 there is a unique uniformly continuous function $\widehat{f}: \widehat{E} \rightarrow F$ extending $g = f \circ \varphi^{-1}$; see the diagram below:

$$\begin{array}{ccc} E & \xleftarrow{\varphi^{-1}} & \varphi(E) \\ & \searrow f & \downarrow g \\ & & F \end{array} \subseteq \widehat{E} \quad \widehat{f} \downarrow F$$

This means that

$$\widehat{f}|_{\varphi(E)} = f \circ \varphi^{-1},$$

which implies that

$$(\widehat{f}|_{\varphi(E)}) \circ \varphi = f,$$

that is, $f = \widehat{f} \circ \varphi$, as illustrated in the diagram below:

$$\begin{array}{ccc} E & \xrightarrow{\varphi} & \widehat{E} \\ & \searrow f & \downarrow \widehat{f} \\ & & F \end{array}$$

If $h: \widehat{E} \rightarrow F$ is any other uniformly continuous function such that $f = h \circ \varphi$, then $g = f \circ \varphi^{-1} = h|_{\varphi(E)}$, so h is a uniformly continuous function extending g , and by Theorem 37.52, we have $h = \widehat{f}$, so \widehat{f} is indeed unique.

Step 9. Uniqueness of the completion $(\widehat{E}, \widehat{d})$ up to a bijective isometry.

Let $(\widehat{E}_1, \widehat{d}_1)$ and $(\widehat{E}_2, \widehat{d}_2)$ be any two completions of (E, d) . Then we have two uniformly continuous isometries $\varphi_1: E \rightarrow \widehat{E}_1$ and $\varphi_2: E \rightarrow \widehat{E}_2$, so by the unique extension property, there exist unique uniformly continuous maps $\widehat{\varphi}_2: \widehat{E}_1 \rightarrow \widehat{E}_2$ and $\widehat{\varphi}_1: \widehat{E}_2 \rightarrow \widehat{E}_1$ such that the following diagrams commute:

$$\begin{array}{ccc} E & \xrightarrow{\varphi_1} & \widehat{E}_1 \\ & \searrow \varphi_2 & \downarrow \widehat{\varphi}_2 \\ & & \widehat{E}_2 \end{array} \quad \begin{array}{ccc} E & \xrightarrow{\varphi_2} & \widehat{E}_2 \\ & \searrow \varphi_1 & \downarrow \widehat{\varphi}_1 \\ & & \widehat{E}_1. \end{array}$$

Consequently we have the following commutative diagrams:

$$\begin{array}{ccc} & \widehat{E}_2 & \\ \varphi_2 \nearrow & \downarrow \widehat{\varphi}_1 & \\ E & \xrightarrow{\varphi_1} & \widehat{E}_1 \\ \varphi_2 \searrow & \downarrow \widehat{\varphi}_2 & \\ & \widehat{E}_2 & \end{array} \quad \begin{array}{ccc} & \widehat{E}_1 & \\ \varphi_1 \nearrow & \downarrow \widehat{\varphi}_2 & \\ E & \xrightarrow{\varphi_2} & \widehat{E}_2 \\ \varphi_1 \searrow & \downarrow \widehat{\varphi}_1 & \\ & \widehat{E}_1 & \end{array}$$

However, $\text{id}_{\widehat{E}_1}$ and $\text{id}_{\widehat{E}_2}$ are uniformly continuous functions making the following diagrams commute

$$\begin{array}{ccc} E & \xrightarrow{\varphi_1} & \widehat{E}_1 \\ \varphi_1 \searrow & \downarrow \text{id}_{\widehat{E}_1} & \\ & \widehat{E}_1 & \end{array} \quad \begin{array}{ccc} E & \xrightarrow{\varphi_2} & \widehat{E}_2 \\ \varphi_2 \searrow & \downarrow \text{id}_{\widehat{E}_2} & \\ & \widehat{E}_2 & \end{array},$$

so by the uniqueness of extensions we must have

$$\widehat{\varphi}_1 \circ \widehat{\varphi}_2 = \text{id}_{\widehat{E}_1} \quad \text{and} \quad \widehat{\varphi}_2 \circ \widehat{\varphi}_1 = \text{id}_{\widehat{E}_2}.$$

This proves that $\widehat{\varphi}_1$ and $\widehat{\varphi}_2$ are mutual inverses. Now, since $\varphi_2 = \widehat{\varphi}_2 \circ \varphi_1$, we have

$$\widehat{\varphi}_2|_{\varphi_1(E)} = \varphi_2 \circ \varphi_1^{-1},$$

and since φ_1^{-1} and φ_2 are isometries, so is $\widehat{\varphi}_2|_{\varphi_1(E)}$. But we saw earlier that $\widehat{\varphi}_2$ is the uniform continuous extension of $\widehat{\varphi}_2|_{\varphi_1(E)}$ and $\varphi_1(E)$ is dense in \widehat{E}_1 , so for any two elements $\alpha, \beta \in \widehat{E}_1$, if (a_n) and (b_n) are sequences in $\varphi_1(E)$ converging to α and β , we have

$$\widehat{d}_2((\widehat{\varphi}_2|_{\varphi_1(E)})(a_n), ((\widehat{\varphi}_2|_{\varphi_1(E)})(b_n)) = \widehat{d}_1(a_n, b_n),$$

and by passing to the limit we get

$$\widehat{d}_2(\widehat{\varphi}_2(\alpha), \widehat{\varphi}_2(\beta)) = \widehat{d}_1(\alpha, \beta),$$

which shows that $\widehat{\varphi}_2$ is an isometry (similarly, $\widehat{\varphi}_1$ is an isometry). □

Remarks:

1. Except for Step 8 and Step 9, the proof of Theorem 37.53 is the proof given in Schwartz [149] (Chapter XI, Section 4, Theorem 1), and Kormogorov and Fomin [105] (Chapter 2, Section 7, Theorem 4).
2. The construction of \widehat{E} relies on the completeness of \mathbb{R} , and so it cannot be used to construct \mathbb{R} from \mathbb{Q} . However, this construction can be modified to yield a construction of \mathbb{R} from \mathbb{Q} .

We show in Section 37.12 that Theorem 37.53 yields a construction of the completion of a normed vector space.

37.10 The Contraction Mapping Theorem

If (E, d) is a nonempty complete metric space, every map, $f: E \rightarrow E$, for which there is some k such that $0 \leq k < 1$ and

$$d(f(x), f(y)) \leq kd(x, y)$$

for all $x, y \in E$, has the very important property that it has a unique fixed point, that is, there is a unique, $a \in E$, such that $f(a) = a$. A map as above is called a *contraction mapping*. Furthermore, the fixed point of a contraction mapping can be computed as the limit of a fast converging sequence.

The fixed point property of contraction mappings is used to show some important theorems of analysis, such as the implicit function theorem and the existence of solutions to certain differential equations. It can also be used to show the existence of fractal sets defined in terms of iterated function systems. Since the proof is quite simple, we prove the fixed point property of contraction mappings. First, observe that a contraction mapping is (uniformly) continuous.

Proposition 37.54. *If (E, d) is a nonempty complete metric space, every contraction mapping, $f: E \rightarrow E$, has a unique fixed point. Furthermore, for every $x_0 \in E$, defining the sequence, (x_n) , such that $x_{n+1} = f(x_n)$, the sequence, (x_n) , converges to the unique fixed point of f .*

Proof. First we prove that f has at most one fixed point. Indeed, if $f(a) = a$ and $f(b) = b$, since

$$d(a, b) = d(f(a), f(b)) \leq kd(a, b)$$

and $0 \leq k < 1$, we must have $d(a, b) = 0$, that is, $a = b$.

Next, we prove that (x_n) is a Cauchy sequence. Observe that

$$\begin{aligned} d(x_2, x_1) &\leq kd(x_1, x_0), \\ d(x_3, x_2) &\leq kd(x_2, x_1) \leq k^2d(x_1, x_0), \\ &\vdots && \vdots \\ d(x_{n+1}, x_n) &\leq kd(x_n, x_{n-1}) \leq \cdots \leq k^n d(x_1, x_0). \end{aligned}$$

Thus, we have

$$\begin{aligned} d(x_{n+p}, x_n) &\leq d(x_{n+p}, x_{n+p-1}) + d(x_{n+p-1}, x_{n+p-2}) + \cdots + d(x_{n+1}, x_n) \\ &\leq (k^{p-1} + k^{p-2} + \cdots + k + 1)k^n d(x_1, x_0) \\ &\leq \frac{k^n}{1-k} d(x_1, x_0). \end{aligned}$$

We conclude that $d(x_{n+p}, x_n)$ converges to 0 when n goes to infinity, which shows that (x_n) is a Cauchy sequence. Since E is complete, the sequence (x_n) has a limit, a . Since f is continuous, the sequence $(f(x_n))$ converges to $f(a)$. But $x_{n+1} = f(x_n)$ converges to a and so $f(a) = a$, the unique fixed point of f . \square

Note that no matter how the starting point x_0 of the sequence (x_n) is chosen, (x_n) converges to the unique fixed point of f . Also, the convergence is fast, since

$$d(x_n, a) \leq \frac{k^n}{1-k} d(x_1, x_0).$$

The Hausdorff distance between compact subsets of a metric space provides a very nice illustration of some of the theorems on complete and compact metric spaces just presented.

Definition 37.40. Given a metric space, (X, d) , for any subset, $A \subseteq X$, for any, $\epsilon \geq 0$, define the ϵ -hull of A as the set

$$V_\epsilon(A) = \{x \in X, \exists a \in A \mid d(a, x) \leq \epsilon\}.$$

See Figure 37.46. Given any two nonempty bounded subsets, A, B of X , define $D(A, B)$, the Hausdorff distance between A and B , by

$$D(A, B) = \inf\{\epsilon \geq 0 \mid A \subseteq V_\epsilon(B) \text{ and } B \subseteq V_\epsilon(A)\}.$$

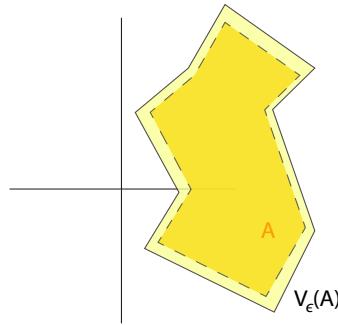

Figure 37.46: The ϵ -hull of a polygonal region A of \mathbb{R}^2

Note that since we are considering nonempty bounded subsets, $D(A, B)$ is well defined (i.e., not infinite). However, D is not necessarily a distance function. It is a distance function if we restrict our attention to nonempty compact subsets of X (actually, it is also a metric on closed and bounded subsets). We let $\mathcal{K}(X)$ denote the set of all nonempty compact subsets of X . The remarkable fact is that D is a distance on $\mathcal{K}(X)$ and that if X is complete or compact, then so is $\mathcal{K}(X)$. The following theorem is taken from Edgar [55].

Theorem 37.55. If (X, d) is a metric space, then the Hausdorff distance, D , on the set, $\mathcal{K}(X)$, of nonempty compact subsets of X is a distance. If (X, d) is complete, then $(\mathcal{K}(X), D)$ is complete and if (X, d) is compact, then $(\mathcal{K}(X), D)$ is compact.

Proof. Since (nonempty) compact sets are bounded, $D(A, B)$ is well defined. Clearly D is symmetric. Assume that $D(A, B) = 0$. Then for every $\epsilon > 0$, $A \subseteq V_\epsilon(B)$, which means that for every $a \in A$, there is some $b \in B$ such that $d(a, b) \leq \epsilon$, and thus, that $A \subseteq \overline{B}$. Since Proposition 37.26 implies that B is closed, $\overline{B} = B$, and we have $A \subseteq B$. Similarly, $B \subseteq A$, and thus, $A = B$. Clearly, if $A = B$, we have $D(A, B) = 0$. It remains to prove the triangle inequality. Assume that $D(A, B) \leq \epsilon_1$ and that $D(B, C) \leq \epsilon_2$. We must show that $D(A, C) \leq \epsilon_1 + \epsilon_2$. This will be accomplished if we can show that $C \subseteq V_{\epsilon_1 + \epsilon_2}(A)$ and $A \subseteq V_{\epsilon_1 + \epsilon_2}(C)$. By assumption and definition of D , $B \subseteq V_{\epsilon_1}(A)$ and $C \subseteq V_{\epsilon_2}(B)$. Then

$$V_{\epsilon_2}(B) \subseteq V_{\epsilon_2}(V_{\epsilon_1}(A)),$$

and since a basic application of the triangle inequality implies that

$$V_{\epsilon_2}(V_{\epsilon_1}(A)) \subseteq V_{\epsilon_1 + \epsilon_2}(A),$$

we get

$$C \subseteq V_{\epsilon_2}(B) \subseteq V_{\epsilon_1 + \epsilon_2}(A).$$

See Figure 37.47.

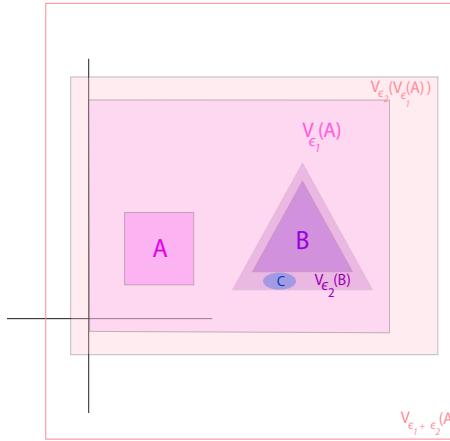

Figure 37.47: Let A be the small pink square and B be the small purple triangle in \mathbb{R}^2 . The periwinkle oval C is contained in $V_{\epsilon_1 + \epsilon_2}(A)$.

Similarly, the conditions $(A, B) \leq \epsilon_1$ and $D(B, C) \leq \epsilon_2$ imply that

$$A \subseteq V_{\epsilon_1}(B), \quad B \subseteq V_{\epsilon_2}(C).$$

Hence

$$A \subseteq V_{\epsilon_1}(B) \subseteq V_{\epsilon_1}(V_{\epsilon_2}(C)) \subseteq V_{\epsilon_1+\epsilon_2}(C),$$

and thus the triangle inequality follows.

Next we need to prove that if (X, d) is complete, then $(\mathcal{K}(X), D)$ is also complete. First we show that if (A_n) is a sequence of nonempty compact sets converging to a nonempty compact set A in the Hausdorff metric, then

$$A = \{x \in X \mid \text{there is a sequence, } (x_n), \text{ with } x_n \in A_n \text{ converging to } x\}.$$

Indeed, if (x_n) is a sequence with $x_n \in A_n$ converging to x and (A_n) converges to A then, for every $\epsilon > 0$, there is some x_n such that $d(x_n, x) \leq \epsilon/2$ and there is some $a_n \in A$ such that $d(a_n, x_n) \leq \epsilon/2$ and thus, $d(a_n, x) \leq \epsilon$, which shows that $x \in \overline{A}$. Since A is compact, it is closed, and $x \in A$. See Figure 37.48.

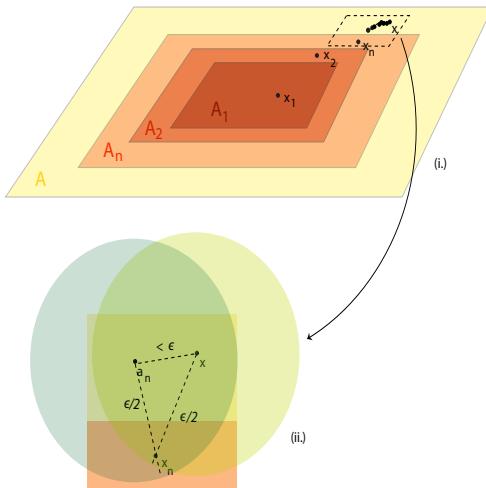

Figure 37.48: Let (A_n) be the sequence of parallelograms converging to A , the large pale yellow parallelogram. Figure (ii.) expands the dashed region and shows why $d(a_n, x) < \epsilon$.

Conversely, since (A_n) converges to A , for every $x \in A$, for every $n \geq 1$, there is some $x_n \in A_n$ such that $d(x_n, x) \leq 1/n$ and the sequence (x_n) converges to x .

Now let (A_n) be a Cauchy sequence in $\mathcal{K}(X)$. It can be proven that (A_n) converges to the set

$$A = \{x \in X \mid \text{there is a sequence, } (x_n), \text{ with } x_n \in A_n \text{ converging to } x\},$$

and that A is nonempty and compact. To prove that A is compact, one proves that it is totally bounded and complete. Details are given in Edgar [55].

Finally we need to prove that if (X, d) is compact, then $(\mathcal{K}(X), D)$ is compact. Since we already know that $(\mathcal{K}(X), D)$ is complete if (X, d) is, it is enough to prove that $(\mathcal{K}(X), D)$ is totally bounded if (X, d) is, which is not hard. \square

In view of Theorem 37.55 and Theorem 37.54, it is possible to define some nonempty compact subsets of X in terms of fixed points of contraction maps. This can be done in terms of iterated function systems, yielding a large class of fractals. However, we will omit this topic and instead refer the reader to Edgar [55].

In Chapter 38 we show how certain fractals can be defined by iterated function systems, using Theorem 37.55 and Theorem 37.54.

Before considering differentials, we need to look at the continuity of linear maps.

37.11 Continuous Linear and Multilinear Maps

If E and F are normed vector spaces, we first characterize when a linear map $f: E \rightarrow F$ is continuous.

Proposition 37.56. *Given two normed vector spaces E and F , for any linear map $f: E \rightarrow F$, the following conditions are equivalent:*

(1) *The function f is continuous at 0.*

(2) *There is a constant $k \geq 0$ such that,*

$$\|f(u)\| \leq k, \text{ for every } u \in E \text{ such that } \|u\| \leq 1.$$

(3) *There is a constant $k \geq 0$ such that,*

$$\|f(u)\| \leq k\|u\|, \text{ for every } u \in E.$$

(4) *The function f is continuous at every point of E .*

Proof. Assume (1). Then for every $\epsilon > 0$, there is some $\eta > 0$ such that, for every $u \in E$, if $\|u\| \leq \eta$, then $\|f(u)\| \leq \epsilon$. Pick $\epsilon = 1$, so that there is some $\eta > 0$ such that, if $\|u\| \leq \eta$, then $\|f(u)\| \leq 1$. If $\|u\| \leq 1$, then $\|\eta u\| \leq \eta\|u\| \leq \eta$, and so, $\|f(\eta u)\| \leq 1$, that is, $\eta\|f(u)\| \leq 1$, which implies $\|f(u)\| \leq \eta^{-1}$. Thus, (2) holds with $k = \eta^{-1}$.

Assume that (2) holds. If $u = 0$, then by linearity, $f(0) = 0$, and thus $\|f(0)\| \leq k\|0\|$ holds trivially for all $k \geq 0$. If $u \neq 0$, then $\|u\| > 0$, and since

$$\left\| \frac{u}{\|u\|} \right\| = 1,$$

we have

$$\left\| f\left(\frac{u}{\|u\|}\right) \right\| \leq k,$$

which implies that

$$\|f(u)\| \leq k\|u\|.$$

Thus, (3) holds.

If (3) holds, then for all $u, v \in E$, we have

$$\|f(v) - f(u)\| = \|f(v - u)\| \leq k\|v - u\|.$$

If $k = 0$, then f is the zero function, and continuity is obvious. Otherwise, if $k > 0$, for every $\epsilon > 0$, if $\|v - u\| \leq \frac{\epsilon}{k}$, then $\|f(v - u)\| \leq \epsilon$, which shows continuity at every $u \in E$. Finally, it is obvious that (4) implies (1). \square

Among other things, Proposition 37.56 shows that a linear map is continuous iff the image of the unit (closed) ball is bounded. Since a continuous linear map satisfies the condition $\|f(u)\| \leq k\|u\|$ (for some $k \geq 0$), it is also uniformly continuous.

If E and F are normed vector spaces, the set of all continuous linear maps $f: E \rightarrow F$ is denoted by $\mathcal{L}(E; F)$.

Using Proposition 37.56, we can define a norm on $\mathcal{L}(E; F)$ which makes it into a normed vector space. This definition has already been given in Chapter 9 (Definition 9.7) but for the reader's convenience, we repeat it here.

Definition 37.41. Given two normed vector spaces E and F , for every continuous linear map $f: E \rightarrow F$, we define the *operator norm* $\|f\|$ of f as

$$\|f\| = \inf \{k \geq 0 \mid \|f(x)\| \leq k\|x\|, \text{ for all } x \in E\} = \sup \{\|f(x)\| \mid \|x\| \leq 1\}.$$

From Definition 37.41, for every continuous linear map $f \in \mathcal{L}(E; F)$, we have

$$\|f(x)\| \leq \|f\|\|x\|,$$

for every $x \in E$. It is easy to verify that $\mathcal{L}(E; F)$ is a normed vector space under the norm of Definition 37.41. Furthermore, if E, F, G , are normed vector spaces, and $f: E \rightarrow F$ and $g: F \rightarrow G$ are continuous linear maps, we have

$$\|g \circ f\| \leq \|g\|\|f\|.$$

We can now show that when $E = \mathbb{R}^n$ or $E = \mathbb{C}^n$, with any of the norms $\|\cdot\|_1$, $\|\cdot\|_2$, or $\|\cdot\|_\infty$, then every linear map $f: E \rightarrow F$ is continuous.

Proposition 37.57. *If $E = \mathbb{R}^n$ or $E = \mathbb{C}^n$, with any of the norms $\|\cdot\|_1$, $\|\cdot\|_2$, or $\|\cdot\|_\infty$, and F is any normed vector space, then every linear map $f: E \rightarrow F$ is continuous.*

Proof. Let (e_1, \dots, e_n) be the standard basis of \mathbb{R}^n (a similar proof applies to \mathbb{C}^n). In view of Proposition 9.3, it is enough to prove the proposition for the norm

$$\|x\|_\infty = \max\{|x_i| \mid 1 \leq i \leq n\}.$$

We have,

$$\|f(v) - f(u)\| = \|f(v - u)\| = \left\| f\left(\sum_{1 \leq i \leq n} (v_i - u_i)e_i\right) \right\| = \left\| \sum_{1 \leq i \leq n} (v_i - u_i)f(e_i) \right\|,$$

and so,

$$\|f(v) - f(u)\| \leq \left(\sum_{1 \leq i \leq n} \|f(e_i)\| \right) \max_{1 \leq i \leq n} |v_i - u_i| = \left(\sum_{1 \leq i \leq n} \|f(e_i)\| \right) \|v - u\|_\infty.$$

By the argument used in Proposition 37.56 to prove that (3) implies (4), f is continuous. \square

Actually, we proved in Theorem 9.5 that if E is a vector space of finite dimension, then any two norms are equivalent, so that they define the same topology. This fact together with Proposition 37.57 prove the following:

Theorem 37.58. *If E is a vector space of finite dimension (over \mathbb{R} or \mathbb{C}), then all norms are equivalent (define the same topology). Furthermore, for any normed vector space F , every linear map $f: E \rightarrow F$ is continuous.*

 If E is a normed vector space of infinite dimension, a linear map $f: E \rightarrow F$ may not be continuous. As an example, let E be the infinite vector space of all polynomials over \mathbb{R} .

Let

$$\|P(X)\| = \max_{0 \leq x \leq 1} |P(x)|.$$

We leave as an exercise to show that this is indeed a norm. Let $F = \mathbb{R}$, and let $f: E \rightarrow F$ be the map defined such that, $f(P(X)) = P(3)$. It is clear that f is linear. Consider the sequence of polynomials

$$P_n(X) = \left(\frac{X}{2}\right)^n.$$

It is clear that $\|P_n\| = \left(\frac{1}{2}\right)^n$, and thus, the sequence P_n has the null polynomial as a limit. However, we have

$$f(P_n(X)) = P_n(3) = \left(\frac{3}{2}\right)^n,$$

and the sequence $f(P_n(X))$ diverges to $+\infty$. Consequently, in view of Proposition 37.15 (1), f is not continuous.

We now consider the continuity of multilinear maps. We treat explicitly bilinear maps, the general case being a straightforward extension.

Proposition 37.59. *Given normed vector spaces E , F and G , for any bilinear map $f: E \times F \rightarrow G$, the following conditions are equivalent:*

(1) *The function f is continuous at $\langle 0, 0 \rangle$.*

2) *There is a constant $k \geq 0$ such that,*

$$\|f(u, v)\| \leq k, \text{ for all } u \in E, v \in F \text{ such that } \|u\|, \|v\| \leq 1.$$

3) *There is a constant $k \geq 0$ such that,*

$$\|f(u, v)\| \leq k\|u\|\|v\|, \text{ for all } u \in E, v \in F.$$

4) *The function f is continuous at every point of $E \times F$.*

Proof. It is similar to that of Proposition 37.56, with a small subtlety in proving that (3) implies (4), namely that two different η 's that are not independent are needed. \square

In contrast to continuous linear maps, which must be uniformly continuous, nonzero continuous bilinear maps are **not** uniformly continuous. Let $f: E \times F \rightarrow G$ be a continuous bilinear map such that $f(a, b) \neq 0$ for some $a \in E$ and some $b \in F$. Consider the sequences (u_n) and (v_n) (with $n \geq 1$) given by

$$\begin{aligned} u_n &= (x_n, y_n) = (na, nb) \\ v_n &= (x'_n, y'_n) = \left(\left(n + \frac{1}{n} \right) a, \left(n + \frac{1}{n} \right) b \right). \end{aligned}$$

Obviously

$$\|v_n - u_n\| \leq \frac{1}{n}(\|a\| + \|b\|),$$

so $\lim_{n \rightarrow \infty} \|v_n - u_n\| = 0$. On the other hand

$$f(x'_n, y'_n) - f(x_n, y_n) = \left(2 + \frac{1}{n^2} \right) f(a, b),$$

and thus $\lim_{n \rightarrow \infty} \|f(x'_n, y'_n) - f(x_n, y_n)\| = 2\|f(a, b)\| \neq 0$, which shows that f is not uniformly continuous, because if this was the case, this limit would be zero.

If E , F , and G , are normed vector spaces, we denote the set of all continuous bilinear maps $f: E \times F \rightarrow G$ by $\mathcal{L}_2(E, F; G)$. Using Proposition 37.59, we can define a norm on $\mathcal{L}_2(E, F; G)$ which makes it into a normed vector space.

Definition 37.42. Given normed vector spaces E , F , and G , for every continuous bilinear map $f: E \times F \rightarrow G$, we define the *norm* $\|f\|$ of f as

$$\begin{aligned}\|f\| &= \inf \{k \geq 0 \mid \|f(x, y)\| \leq k\|x\|\|y\|, \text{ for all } x \in E, y \in F\} \\ &= \sup \{\|f(x, y)\| \mid \|x\|, \|y\| \leq 1\}.\end{aligned}$$

From Definition 37.41, for every continuous bilinear map $f \in \mathcal{L}_2(E, F; G)$, we have

$$\|f(x, y)\| \leq \|f\|\|x\|\|y\|,$$

for all $x, y \in E$. It is easy to verify that $\mathcal{L}_2(E, F; G)$ is a normed vector space under the norm of Definition 37.42.

Given a bilinear map $f: E \times F \rightarrow G$, for every $u \in E$, we obtain a linear map denoted $fu: F \rightarrow G$, defined such that, $fu(v) = f(u, v)$. Furthermore, since

$$\|f(x, y)\| \leq \|f\|\|x\|\|y\|,$$

it is clear that fu is continuous. We can then consider the map $\varphi: E \rightarrow \mathcal{L}(F; G)$, defined such that, $\varphi(u) = fu$, for any $u \in E$, or equivalently, such that,

$$\varphi(u)(v) = f(u, v).$$

Actually, it is easy to show that φ is linear and continuous, and that $\|\varphi\| = \|f\|$. Thus, $f \mapsto \varphi$ defines a map from $\mathcal{L}_2(E, F; G)$ to $\mathcal{L}(E; \mathcal{L}(F; G))$. We can also go back from $\mathcal{L}(E; \mathcal{L}(F; G))$ to $\mathcal{L}_2(E, F; G)$. We summarize all this in the following proposition.

Proposition 37.60. Let E, F, G be three normed vector spaces. The map $f \mapsto \varphi$, from $\mathcal{L}_2(E, F; G)$ to $\mathcal{L}(E; \mathcal{L}(F; G))$, defined such that, for every $f \in \mathcal{L}_2(E, F; G)$,

$$\varphi(u)(v) = f(u, v),$$

is an isomorphism of vector spaces, and furthermore, $\|\varphi\| = \|f\|$.

As a corollary of Proposition 37.60, we get the following proposition which will be useful when we define second-order derivatives.

Proposition 37.61. Let E, F be normed vector spaces. The map app from $\mathcal{L}(E; F) \times E$ to F , defined such that, for every $f \in \mathcal{L}(E; F)$, for every $u \in E$,

$$app(f, u) = f(u),$$

is a continuous bilinear map.

Remark: If E and F are nontrivial, it can be shown that $\|\text{app}\| = 1$. It can also be shown that composition

$$\circ: \mathcal{L}(E; F) \times \mathcal{L}(F; G) \rightarrow \mathcal{L}(E; G),$$

is bilinear and continuous.

The above propositions and definition generalize to arbitrary n -multilinear maps, with $n \geq 2$. Proposition 37.59 extends in the obvious way to any n -multilinear map $f: E_1 \times \cdots \times E_n \rightarrow F$, but condition (3) becomes:

There is a constant $k \geq 0$ such that,

$$\|f(u_1, \dots, u_n)\| \leq k\|u_1\| \cdots \|u_n\|, \text{ for all } u_1 \in E_1, \dots, u_n \in E_n.$$

Definition 37.42 also extends easily to

$$\begin{aligned} \|f\| &= \inf \{k \geq 0 \mid \|f(x_1, \dots, x_n)\| \leq k\|x_1\| \cdots \|x_n\|, \text{ for all } x_i \in E_i, 1 \leq i \leq n\} \\ &= \sup \{\|f(x_1, \dots, x_n)\| \mid \|x_1\|, \dots, \|x_n\| \leq 1\}. \end{aligned}$$

Proposition 37.60 is also easily extended, and we get an isomorphism between continuous n -multilinear maps in $\mathcal{L}_n(E_1, \dots, E_n; F)$, and continuous linear maps in

$$\mathcal{L}(E_1; \mathcal{L}(E_2; \dots; \mathcal{L}(E_n; F)))$$

An obvious extension of Proposition 37.61 also holds.

Definition 37.43. A normed vector space $(E, \|\cdot\|)$ over \mathbb{R} (or \mathbb{C}) which is a complete metric space for the distance $d(u, v) = \|v - u\|$, is called a *Banach space*.

The following theorem is a key result of the theory of Banach spaces worth proving.

Theorem 37.62. *If E and F are normed vector spaces, and if F is a Banach space, then $\mathcal{L}(E; F)$ is a Banach space (with the operator norm).*

Proof. Let $(f)_{n \geq 1}$ be a Cauchy sequence of continuous linear maps $f_n: E \rightarrow F$. We proceed in several steps.

Step 1. Define the pointwise limit $f: E \rightarrow F$ of the sequence $(f_n)_{n \geq 1}$.

Since $(f)_{n \geq 1}$ is a Cauchy sequence, for every $\epsilon > 0$, there is some $N > 0$ such that $\|f_m - f_n\| < \epsilon$ for all $m, n \geq N$. Since $\|\cdot\|$ is the operator norm, we deduce that for any $u \in E$, we have

$$\|f_m(u) - f_n(u)\| = \|(f_m - f_n)(u)\| \leq \|f_m - f_n\| \|u\| \leq \epsilon \|u\| \quad \text{for all } m, n \geq N,$$

that is,

$$\|f_m(u) - f_n(u)\| \leq \epsilon \|u\| \quad \text{for all } m, n \geq N. \tag{*1}$$

If $u = 0$, then $f_m(0) = f_n(0) = 0$ for all m, n , so the sequence $(f_n(0))$ is a Cauchy sequence in F converging to 0. If $u \neq 0$, by replacing ϵ by $\epsilon/\|u\|$, we see that the sequence $(f_n(u))$ is a Cauchy sequence in F . Since F is complete, the sequence $(f_n(u))$ has a limit which we denote by $f(u)$. This defines our candidate limit function f by

$$f(u) = \lim_{n \rightarrow \infty} f_n(u).$$

It remains to prove that

1. f is linear.
2. f is continuous.
3. f is the limit of (f_n) for the operator norm.

Step 2. The function f is linear.

Recall that in a normed vector space, addition and multiplication by a fixed scalar are continuous (since $\|u + v\| \leq \|u\| + \|v\|$ and $\|\lambda u\| \leq |\lambda| \|u\|$). Thus by definition of f and since the f_n are linear we have

$$\begin{aligned} f(u + v) &= \lim_{n \rightarrow \infty} f_n(u + v) && \text{by definition of } f \\ &= \lim_{n \rightarrow \infty} (f_n(u) + f_n(v)) && \text{by linearity of } f_n \\ &= \lim_{n \rightarrow \infty} f_n(u) + \lim_{n \rightarrow \infty} f_n(v) && \text{since } + \text{ is continuous} \\ &= f(u) + f(v) && \text{by definition of } f. \end{aligned}$$

Similarly,

$$\begin{aligned} f(\lambda u) &= \lim_{n \rightarrow \infty} f_n(\lambda u) && \text{by definition of } f \\ &= \lim_{n \rightarrow \infty} \lambda f_n(u) && \text{by linearity of } f_n \\ &= \lambda \lim_{n \rightarrow \infty} f_n(u) && \text{by continuity of scalar multiplication} \\ &= \lambda f(u) && \text{by definition of } f. \end{aligned}$$

Therefore, f is linear.

Step 3. The function f is continuous.

Since $(f_n)_{n \geq 1}$ is a Cauchy sequence, for every $\epsilon > 0$, there is some $N > 0$ such that $\|f_m - f_n\| < \epsilon$ for all $m, n \geq N$. Since $f_m = f_n + f_m - f_n$, we get $\|f_m\| \leq \|f_n\| + \|f_m - f_n\|$, which implies that

$$\|f_m\| \leq \|f_n\| + \epsilon \quad \text{for all } m, n \geq N. \tag{*_2}$$

Using $(*_2)$, we also have

$$\|f_m(u)\| \leq \|f_m\| \|u\| \leq (\|f_n\| + \epsilon) \|u\| \quad \text{for all } m, n \geq N,$$

that is,

$$\|f_m(u)\| \leq (\|f_n\| + \epsilon) \|u\| \quad \text{for all } m, n \geq N. \quad (*_3)$$

Hold $n \geq N$ fixed and let m tend to $+\infty$ in $(*_3)$. Since the norm is continuous, we get

$$\|f(u)\| \leq (\|f_n\| + \epsilon) \|u\|,$$

which shows that f is continuous.

Step 4. The function f is the limit of (f_n) for the operator norm.

Recall $(*_1)$:

$$\|f_m(u) - f_n(u)\| \leq \epsilon \|u\| \quad \text{for all } m, n \geq N. \quad (*_1)$$

Hold $n \geq N$ fixed but this time let m tend to $+\infty$ in $(*_1)$. By continuity of the norm we get

$$\|f(u) - f_n(u)\| = \|(f - f_n)(u)\| \leq \epsilon \|u\|.$$

By definition of the operator norm,

$$\|f - f_n\| = \sup\{\|(f - f_n)(u)\| \mid \|u\| = 1\} \leq \epsilon \quad \text{for all } n \geq N,$$

which proves that f_n converges to f for the operator norm. \square

As a special case of Theorem 37.62, if we let $F = \mathbb{R}$ (or $F = \mathbb{C}$ in the case of complex vector spaces) we see that $E' = \mathcal{L}(E; \mathbb{R})$ (or $E' = \mathcal{L}(E; \mathbb{C})$) is complete (since \mathbb{R} and \mathbb{C} are complete). The space E' of continuous linear forms on E is called the *dual* of E . It is a subspace of the *algebraic dual* E^* of E which consists of *all* linear forms on E , not necessarily continuous.

It can also be shown that if E, F and G are normed vector spaces, and if G is a Banach space, then $\mathcal{L}_2(E, F; G)$ is a Banach space. The proof is essentially identical.

37.12 Completion of a Normed Vector Space

An easy corollary of Theorem 37.53 and Theorem 37.52 is that every normed vector space can be embedded in a complete normed vector space, that is, a Banach space.

Theorem 37.63. *If $(E, \|\cdot\|)$ is a normed vector space, then its completion $(\widehat{E}, \widehat{d})$ as a metric space (where E is given the metric $d(x, y) = \|x - y\|$) can be given a unique vector space structure extending the vector space structure on E , and a norm $\|\cdot\|_{\widehat{E}}$, so that $(\widehat{E}, \|\cdot\|_{\widehat{E}})$ is a Banach space, and the metric \widehat{d} is associated with the norm $\|\cdot\|_{\widehat{E}}$. Furthermore, the isometry $\varphi: E \rightarrow \widehat{E}$ is a linear isometry.*

Proof. The addition operation $+: E \times E \rightarrow E$ is uniformly continuous because

$$\|(u' + v') - (u'' + v'')\| \leq \|u' - u''\| + \|v' - v''\|.$$

It is not hard to show that $\widehat{E} \times \widehat{E}$ is a complete metric space and that $E \times E$ is dense in $\widehat{E} \times \widehat{E}$. Then, by Theorem 37.52, the uniformly continuous function $+$ has a unique continuous extension $+: \widehat{E} \times \widehat{E} \rightarrow \widehat{E}$.

The map $\cdot: \mathbb{R} \times E \rightarrow E$ is not uniformly continuous, but for any fixed $\lambda \in \mathbb{R}$, the map $L_\lambda: E \rightarrow E$ given by $L_\lambda(u) = \lambda \cdot u$ is uniformly continuous, so by Theorem 37.52 the function L_λ has a unique continuous extension $L_\lambda: \widehat{E} \rightarrow \widehat{E}$, which we use to define the scalar multiplication $\cdot: \mathbb{R} \times \widehat{E} \rightarrow \widehat{E}$. It is easily checked that with the above addition and scalar multiplication, \widehat{E} is a vector space.

Since the norm $\|\cdot\|$ on E is uniformly continuous, it has a unique continuous extension $\|\cdot\|_{\widehat{E}}: \widehat{E} \rightarrow \mathbb{R}_+$. The identities $\|u + v\| \leq \|u\| + \|v\|$ and $\|\lambda u\| \leq |\lambda| \|u\|$ extend to \widehat{E} by continuity. The equation

$$d(u, v) = \|u - v\|$$

also extends to \widehat{E} by continuity and yields

$$\widehat{d}(\alpha, \beta) = \|\alpha - \beta\|_{\widehat{E}},$$

which shows that $\|\cdot\|_{\widehat{E}}$ is indeed a norm, and that the metric \widehat{d} is associated to it. Finally, it is easy to verify that the map φ is linear. The uniqueness of the structure of normed vector space follows from the uniqueness of continuous extensions in Theorem 37.52. \square

Theorem 37.63 and Theorem 37.52 will be used to show that every Hermitian space can be embedded in a Hilbert space.

The following version of Theorem 37.52 for normed vector spaces is needed in the theory of integration.

Theorem 37.64. *Let E and F be two normed vector spaces, let E_0 be a dense subspace of E , and let $f_0: E_0 \rightarrow F$ be a continuous function. If f_0 is uniformly continuous and if F is complete, then there is a unique uniformly continuous function $f: E \rightarrow F$ extending f_0 . Furthermore, if f_0 is a continuous linear map, then f is also a linear continuous map, and $\|f\| = \|f_0\|$.*

Proof. We only need to prove the second statement. Given any two vectors $x, y \in E$, since E_0 is dense on E we can pick sequences (x_n) and (y_n) of vectors $x_n, y_n \in E_0$ such that $x = \lim_{n \rightarrow \infty} x_n$ and $y = \lim_{n \rightarrow \infty} y_n$. Since addition and scalar multiplication are continuous, we get

$$\begin{aligned} x + y &= \lim_{n \rightarrow \infty} (x_n + y_n) \\ \lambda x &= \lim_{n \rightarrow \infty} (\lambda x_n) \end{aligned}$$

for any $\lambda \in \mathbb{R}$ (or $\lambda \in \mathbb{C}$). Since $f(x)$ is defined by

$$f(x) = \lim_{n \rightarrow \infty} f_0(x_n)$$

independently of the sequence (x_n) converging to x , and similarly for $f(y)$ and $f(x + y)$, since f_0 is linear, we have

$$\begin{aligned} f(x + y) &= \lim_{n \rightarrow \infty} f_0(x_n + y_n) \\ &= \lim_{n \rightarrow \infty} (f_0(x_n) + f_0(y_n)) \\ &= \lim_{n \rightarrow \infty} f_0(x_n) + \lim_{n \rightarrow \infty} f_0(y_n) \\ &= f(x) + f(y). \end{aligned}$$

Similarly,

$$\begin{aligned} f(\lambda x) &= \lim_{n \rightarrow \infty} f_0(\lambda x_n) \\ &= \lim_{n \rightarrow \infty} \lambda f_0(x_n) \\ &= \lambda \lim_{n \rightarrow \infty} f_0(x_n) \\ &= \lambda f(x). \end{aligned}$$

Therefore, f is linear. Since the norm is continuous, we have

$$\|f(x)\| = \left\| \lim_{n \rightarrow \infty} f_0(x_n) \right\| = \lim_{n \rightarrow \infty} \|f_0(x_n)\|,$$

and since f_0 is continuous

$$\|f_0(x_n)\| \leq \|f_0\| \|x_n\| \quad \text{for all } n \geq 1,$$

so we get

$$\lim_{n \rightarrow \infty} \|f_0(x_n)\| \leq \lim_{n \rightarrow \infty} \|f_0\| \|x_n\| \quad \text{for all } n \geq 1,$$

that is,

$$\|f(x)\| \leq \|f_0\| \|x\|.$$

Since

$$\|f\| = \sup_{\|x\|=1, x \in E} \|f(x)\|,$$

we deduce that $\|f\| \leq \|f_0\|$. But since $E_0 \subseteq E$ and f agrees with f_0 on E_0 , we also have

$$\|f_0\| = \sup_{\|x\|=1, x \in E_0} \|f_0(x)\| = \sup_{\|x\|=1, x \in E_0} \|f(x)\| \leq \sup_{\|x\|=1, x \in E} \|f(x)\| = \|f\|,$$

and thus $\|f\| = \|f_0\|$. □

Finally, we consider normed affine spaces.

37.13 Normed Affine Spaces

For geometric applications, we will need to consider affine spaces (E, \overrightarrow{E}) where the associated space of translations \overrightarrow{E} is a vector space equipped with a norm.

Definition 37.44. Given an affine space (E, \overrightarrow{E}) , where the space of translations \overrightarrow{E} is a vector space over \mathbb{R} or \mathbb{C} , we say that (E, \overrightarrow{E}) is a *normed affine space* if \overrightarrow{E} is a normed vector space with norm $\| \cdot \|$.

Given a normed affine space, there is a natural metric on E itself, defined such that

$$d(a, b) = \|\overrightarrow{ab}\|.$$

Observe that this metric is invariant under translation, that is,

$$d(a + u, b + u) = d(a, b).$$

Also, for every fixed $a \in E$ and $\lambda > 0$, if we consider the map $h: E \rightarrow E$, defined such that,

$$h(x) = a + \lambda \overrightarrow{ax},$$

then $d(h(x), h(y)) = \lambda d(x, y)$.

Note that the map $(a, b) \mapsto \overrightarrow{ab}$ from $E \times E$ to \overrightarrow{E} is continuous, and similarly for the map $a \mapsto a + u$ from $E \times \overrightarrow{E}$ to E . In fact, the map $u \mapsto a + u$ is a homeomorphism from \overrightarrow{E} to E_a .

Of course, \mathbb{R}^n is a normed affine space under the Euclidean metric, and it is also complete.

If an affine space E is a finite direct sum $(E_1, a_1) \oplus \cdots \oplus (E_m, a_m)$, and each E_i is also a normed affine space with norm $\| \cdot \|_i$, we make $(E_1, a_1) \oplus \cdots \oplus (E_m, a_m)$ into a normed affine space, by giving it the norm

$$\|(x_1, \dots, x_n)\| = \max(\|x_1\|_1, \dots, \|x_n\|_n).$$

Similarly, the finite product $E_1 \times \cdots \times E_m$ is made into a normed affine space, under the same norm.

We are now ready to define the derivative (or differential) of a map between two normed affine spaces. This will lead to tangent spaces to curves and surfaces (in normed affine spaces).

37.14 Futher Readings

A thorough treatment of general topology can be found in Munkres [131, 130], Dixmier [51], Lang [111, 112], Schwartz [150, 149], Bredon [30], and the classic, Seifert and Threlfall [155].

Chapter 38

A Detour On Fractals

38.1 Iterated Function Systems and Fractals

A pleasant application of the Hausdorff distance and of the fixed point theorem for contracting mappings is a method for defining a class of “self-similar” fractals. For this, we can use iterated function systems.

Definition 38.1. Given a metric space, (X, d) , an *iterated function system*, for short, an *ifs*, is a finite sequence of functions, (f_1, \dots, f_n) , where each $f_i: X \rightarrow X$ is a contracting mapping. A nonempty compact subset, K , of X is an *invariant set (or attractor)* for the ifs, (f_1, \dots, f_n) , if

$$K = f_1(K) \cup \dots \cup f_n(K).$$

The major result about ifs's is the following:

Theorem 38.1. *If (X, d) is a nonempty complete metric space, then every iterated function system, (f_1, \dots, f_n) , has a unique invariant set, A , which is a nonempty compact subset of X . Furthermore, for every nonempty compact subset, A_0 , of X , this invariant set, A , if the limit of the sequence, (A_m) , where $A_{m+1} = f_1(A_m) \cup \dots \cup f_n(A_m)$.*

Proof. Since X is complete, by Theorem 37.55, the space $(\mathcal{K}(X), D)$ is a complete metric space. The theorem will follow from Theorem 37.54 if we can show that the map, $F: \mathcal{K}(X) \rightarrow \mathcal{K}(X)$, defined such that

$$F(K) = f_1(K) \cup \dots \cup f_n(K),$$

for every nonempty compact set, K , is a contracting mapping. Let A, B be any two nonempty compact subsets of X and consider any $\eta \geq D(A, B)$. Since each $f_i: X \rightarrow X$ is a contracting mapping, there is some λ_i , with $0 \leq \lambda_i < 1$, such that

$$d(f_i(a), f_i(b)) \leq \lambda_i d(a, b),$$

for all $a, b \in X$. Let $\lambda = \max\{\lambda_1, \dots, \lambda_n\}$. We claim that

$$D(F(A), F(B)) \leq \lambda D(A, B).$$

For any $x \in F(A) = f_1(A) \cup \dots \cup f_n(A)$, there is some $a_i \in A_i$ such that $x = f_i(a_i)$ and since $\eta \geq D(A, B)$, there is some $b_i \in B$ such that

$$d(a_i, b_i) \leq \eta,$$

and thus,

$$d(x, f_i(b_i)) = d(f_i(a_i), f_i(b_i)) \leq \lambda_i d(a_i, b_i) \leq \lambda \eta.$$

This shows that

$$F(A) \subseteq V_{\lambda \eta}(F(B)).$$

Similarly, we can prove that

$$F(B) \subseteq V_{\lambda \eta}(F(A)),$$

and since this holds for all $\eta \geq D(A, B)$, we proved that

$$D(F(A), F(B)) \leq \lambda D(A, B)$$

where $\lambda = \max\{\lambda_1, \dots, \lambda_n\}$. Since $0 \leq \lambda_i < 1$, we have $0 \leq \lambda < 1$ and F is indeed a contracting mapping. \square

Theorem 38.1 justifies the existence of many familiar “self-similar” fractals. One of the best known fractals is the *Sierpinski gasket*.

Example 38.1. Consider an equilateral triangle with vertices a, b, c , and let f_1, f_2, f_3 be the dilations of centers a, b, c and ratio $1/2$. The Sierpinski gasket is the invariant set of the ifs (f_1, f_2, f_3) . The dilations f_1, f_2, f_3 can be defined explicitly as follows, assuming that $a = (-1/2, 0)$, $b = (1/2, 0)$, and $c = (0, \sqrt{3}/2)$. The contractions f_1, f_2, f_3 are specified by

$$\begin{aligned} x' &= \frac{1}{2}x - \frac{1}{4}, \\ y' &= \frac{1}{2}y, \end{aligned}$$

$$\begin{aligned} x' &= \frac{1}{2}x + \frac{1}{4}, \\ y' &= \frac{1}{2}y, \end{aligned}$$

and

$$\begin{aligned} x' &= \frac{1}{2}x, \\ y' &= \frac{1}{2}y + \frac{\sqrt{3}}{4}. \end{aligned}$$

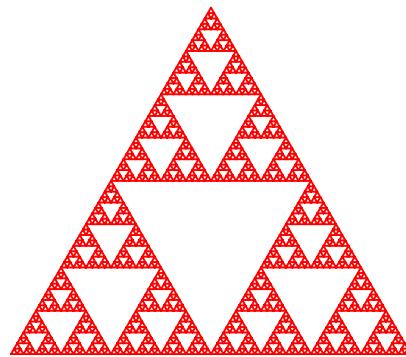

Figure 38.1: The Sierpinski gasket

We wrote a *Mathematica* program that iterates any finite number of affine maps on any input figure consisting of combinations of points, line segments, and polygons (with their interior points). Starting with the edges of the triangle a, b, c , after 6 iterations, we get the picture shown in Figure 38.1.

It is amusing that the same fractal is obtained no matter what the initial nonempty compact figure is. It is interesting to see what happens if we start with a solid triangle (with its interior points). The result after 6 iterations is shown in Figure 38.2. The convergence towards the Sierpinski gasket is very fast. Incidentally, there are many other ways of defining the Sierpinski gasket.

A nice variation on the theme of the Sierpinski gasket is the *Sierpinski dragon*.

Example 38.2. The Sierpinski dragon is specified by the following three contractions:

$$\begin{aligned}x' &= -\frac{1}{4}x - \frac{\sqrt{3}}{4}y + \frac{3}{4}, \\y' &= \frac{\sqrt{3}}{4}x - \frac{1}{4}y + \frac{\sqrt{3}}{4}, \\x' &= -\frac{1}{4}x + \frac{\sqrt{3}}{4}y - \frac{3}{4}, \\y' &= -\frac{\sqrt{3}}{4}x - \frac{1}{4}y + \frac{\sqrt{3}}{4}, \\x' &= \frac{1}{2}x, \\y' &= \frac{1}{2}y + \frac{\sqrt{3}}{2}.\end{aligned}$$

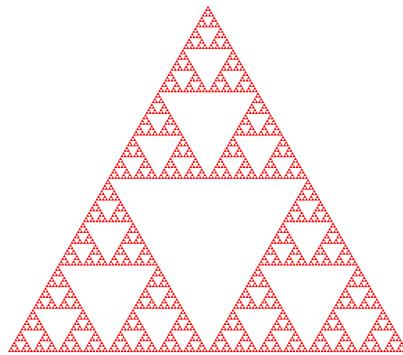

Figure 38.2: The Sierpinski gasket, version 2

The result of 7 iterations starting from the line segment $(-1, 0), (1, 0)$, is shown in Figure 38.3. This curve converges to the boundary of the Sierpinski gasket.

A different kind of fractal is the *Heighway dragon*.

Example 38.3. The Heighway dragon is specified by the following two contractions:

$$\begin{aligned}x' &= \frac{1}{2}x - \frac{1}{2}y, \\y' &= \frac{1}{2}x + \frac{1}{2}y,\end{aligned}$$

$$\begin{aligned}x' &= -\frac{1}{2}x - \frac{1}{2}y, \\y' &= \frac{1}{2}x - \frac{1}{2}y + 1.\end{aligned}$$

It can be shown that for any number of iterations, the polygon does not cross itself. This means that no edge is traversed twice and that if a point is traversed twice, then this point is the endpoint of some edge. The result of 13 iterations, starting with the line segment $((0, 0), (0, 1))$, is shown in Figure 38.4.

The Heighway dragon turns out to fill a closed and bounded set. It can also be shown that the plane can be tiled with copies of the Heighway dragon.

Another well known example is the *Koch curve*.

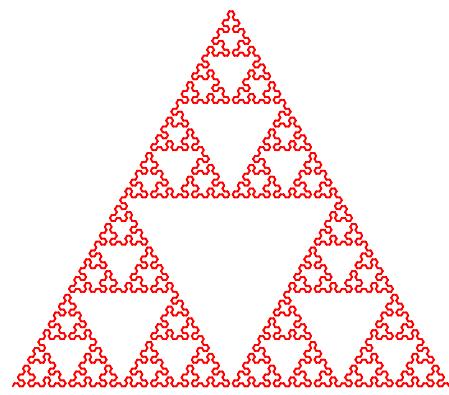

Figure 38.3: The Sierpinski dragon

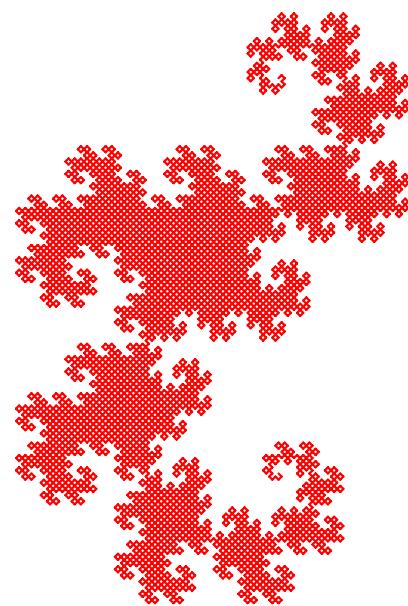

Figure 38.4: The Heighway dragon

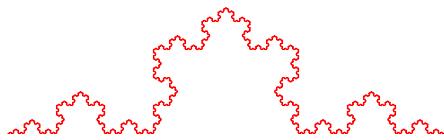

Figure 38.5: The Koch curve

Example 38.4. The Koch curve is specified by the following four contractions:

$$\begin{aligned}x' &= \frac{1}{3}x - \frac{2}{3}, \\y' &= \frac{1}{3}y,\end{aligned}$$

$$\begin{aligned}x' &= \frac{1}{6}x - \frac{\sqrt{3}}{6}y - \frac{1}{6}, \\y' &= \frac{\sqrt{3}}{6}x + \frac{1}{6}y + \frac{\sqrt{3}}{6},\end{aligned}$$

$$\begin{aligned}x' &= \frac{1}{6}x + \frac{\sqrt{3}}{6}y + \frac{1}{6}, \\y' &= -\frac{\sqrt{3}}{6}x + \frac{1}{6}y + \frac{\sqrt{3}}{6},\end{aligned}$$

$$\begin{aligned}x' &= \frac{1}{3}x + \frac{2}{3}, \\y' &= \frac{1}{3}y.\end{aligned}$$

The Koch curve is an example of a continuous curve which is nowhere differentiable (because it “wiggles” too much). It is a curve of infinite length. The result of 6 iterations, starting with the line segment $((-1, 0), (1, 0))$, is shown in Figure 38.5.

The curve obtained by putting three Koch curves together on the sides of an equilateral triangle is known as the *snowflake curve* (for obvious reasons, see below!).

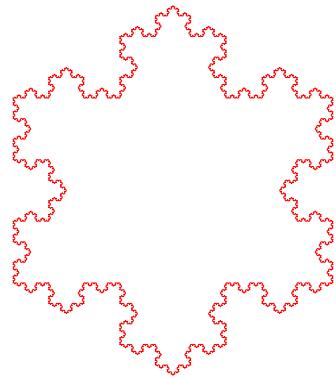

Figure 38.6: The snowflake curve

Example 38.5. The snowflake curve obtained after 5 iterations is shown in Figure 38.6.

The snowflake curve is an example of a closed curve of infinite length bounding a finite area.

We conclude with another famous example, a variant of the *Hilbert curve*.

Example 38.6. This version of the Hilbert curve is defined by the following four contractions:

$$\begin{aligned}x' &= \frac{1}{2}x - \frac{1}{2}, \\y' &= \frac{1}{2}y + 1,\end{aligned}$$

$$\begin{aligned}x' &= \frac{1}{2}x + \frac{1}{2}, \\y' &= \frac{1}{2}y + 1,\end{aligned}$$

$$\begin{aligned}x' &= -\frac{1}{2}y + 1, \\y' &= \frac{1}{2}x + \frac{1}{2},\end{aligned}$$

$$\begin{aligned}x' &= \frac{1}{2}y - 1, \\y' &= -\frac{1}{2}x + \frac{1}{2}.\end{aligned}$$

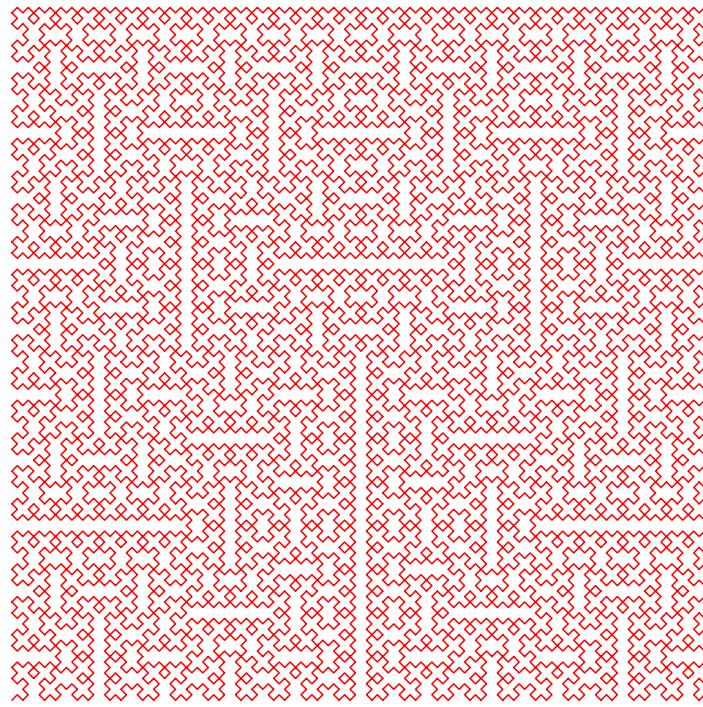

Figure 38.7: A Hilbert curve

This continuous curve is a space-filling curve, in the sense that its image is the entire unit square. The result of 6 iterations, starting with the two line segments $((-1, 0), (0, 1))$ and $((0, 1), (1, 0))$, is shown in Figure 38.7.

For more on iterated function systems and fractals, we recommend Edgar [55].

Chapter 39

Differential Calculus

39.1 Directional Derivatives, Total Derivatives

This chapter contains a review of basic notions of differential calculus. First, we review the definition of the derivative of a function $f: \mathbb{R} \rightarrow \mathbb{R}$. Next, we define directional derivatives and the total derivative of a function $f: E \rightarrow F$ between normed affine spaces. Basic properties of derivatives are shown, including the chain rule. We show how derivatives are represented by Jacobian matrices. The mean value theorem is stated, as well as the implicit function theorem and the inverse function theorem. Diffeomorphisms and local diffeomorphisms are defined. Tangent spaces are defined. Higher-order derivatives are defined, as well as the Hessian. Schwarz's lemma (about the commutativity of partials) is stated. Several versions of Taylor's formula are stated, and a famous formula due to Faà di Bruno's is given.

We first review the notion of the derivative of a real-valued function whose domain is an open subset of \mathbb{R} .

Let $f: A \rightarrow \mathbb{R}$, where A is a nonempty open subset of \mathbb{R} , and consider any $a \in A$. The main idea behind the concept of the derivative of f at a , denoted by $f'(a)$, is that locally around a (that is, in some small open set $U \subseteq A$ containing a), the function f is approximated linearly¹ by the map

$$x \mapsto f(a) + f'(a)(x - a).$$

As pointed out by Dieudonné in the early 1960s, it is an “unfortunate accident” that if V is vector space of dimension one, then there is a bijection between the space V^* of linear forms defined on V and the field of scalars. As a consequence, the derivative of a real-valued function f defined on an open subset A of the reals can be defined as the scalar $f'(a)$ (for any $a \in A$). But as soon as f is a function of several arguments, the scalar interpretation of the derivative breaks down.

¹Actually, the approximation is affine, but everybody commits this abuse of language.

Part of the difficulty in extending the idea of derivative to more complex spaces is to give an adequate notion of linear approximation. The key idea is to use linear maps. This could be carried out in terms of matrices but it turns out that this neither shortens nor simplifies proofs. In fact, this is often the opposite.

We admit that the more intrinsic definition of the notion of derivative f'_a at a point a of a function $f: E \rightarrow F$ between two normed (affine) spaces E and F as a linear map requires a greater effort to be grasped, but we feel that the advantages of this definition outweigh its degree of abstraction. In particular, it yields a clear notion of the derivative of a function $f: M_m(\mathbb{R}) \rightarrow M_n(\mathbb{R})$ defined from $m \times m$ matrices to $n \times n$ matrices (many definitions make use of partial derivatives with respect to matrices that do make any sense). But more importantly, the definition of the derivative as a linear map makes it clear that whether the space E or the space F is infinite dimensional does not matter. This is important in optimization theory where the natural space of solutions of the problem is often an infinite dimensional function space. Of course, to carry out computations one need to pick finite bases and to use Jacobian matrices, but this is a different matter.

Let us now review the formal definition of the derivative of a real-valued function.

Definition 39.1. Let A be any nonempty open subset of \mathbb{R} , and let $a \in A$. For any function $f: A \rightarrow \mathbb{R}$, the *derivative of f at $a \in A$* is the limit (if it exists)

$$\lim_{h \rightarrow 0, h \in U} \frac{f(a + h) - f(a)}{h},$$

where $U = \{h \in \mathbb{R} \mid a + h \in A, h \neq 0\}$. This limit is denoted by $f'(a)$, or $Df(a)$, or $\frac{df}{dx}(a)$. If $f'(a)$ exists for every $a \in A$, we say that f is *differentiable on A* . In this case, the map $a \mapsto f'(a)$ is denoted by f' , or Df , or $\frac{df}{dx}$.

Note that since A is assumed to be open, $A - \{a\}$ is also open, and since the function $h \mapsto a + h$ is continuous and U is the inverse image of $A - \{a\}$ under this function, U is indeed open and the definition makes sense.

We can also define $f'(a)$ as follows: there is some function ϵ , such that,

$$f(a + h) = f(a) + f'(a) \cdot h + \epsilon(h)h,$$

whenever $a + h \in A$, where $\epsilon(h)$ is defined for all h such that $a + h \in A$, and

$$\lim_{h \rightarrow 0, h \in U} \epsilon(h) = 0.$$

Remark: We can also define the notion of *derivative of f at a on the left*, and *derivative of f at a on the right*. For example, we say that the *derivative of f at a on the left* is the limit $f'(a_-)$ (if it exists)

$$\lim_{h \rightarrow 0, h \in U} \frac{f(a + h) - f(a)}{h},$$

where $U = \{h \in \mathbb{R} \mid a + h \in A, h < 0\}$.

If a function f as in Definition 39.1 has a derivative $f'(a)$ at a , then it is continuous at a . If f is differentiable on A , then f is continuous on A . The composition of differentiable functions is differentiable.

Remark: A function f has a derivative $f'(a)$ at a iff the derivative of f on the left at a and the derivative of f on the right at a exist, and if they are equal. Also, if the derivative of f on the left at a exists, then f is continuous on the left at a (and similarly on the right).

We would like to extend the notion of derivative to functions $f: A \rightarrow F$, where E and F are normed affine spaces, and A is some nonempty open subset of E . The first difficulty is to make sense of the quotient

$$\frac{f(a+h) - f(a)}{h}.$$

If E and F are normed affine spaces, it will be notationally convenient to assume that the vector space associated with E is denoted by \vec{E} , and that the vector space associated with F is denoted as \vec{F} .

Since F is a normed affine space, making sense of $f(a+h) - f(a)$ is easy: we can define this as $\overrightarrow{f(a)f(a+h)}$, the unique vector translating $f(a)$ to $f(a+h)$. We should note however, that this quantity is a vector and not a point. Nevertheless, in defining derivatives, it is notationally more pleasant to denote $\overrightarrow{f(a)f(a+h)}$ by $f(a+h) - f(a)$. Thus, in the rest of this chapter, the vector \vec{ab} will be denoted by $b - a$. But now, how do we define the quotient by a vector? Well, we don't!

A first possibility is to consider the *directional derivative* with respect to a vector $u \neq 0$ in \vec{E} . We can consider the vector $f(a+tu) - f(a)$, where $t \in \mathbb{R}$ (or $t \in \mathbb{C}$). Now,

$$\frac{f(a+tu) - f(a)}{t}$$

makes sense. The idea is that in E , the points of the form $a+tu$ for t in some small interval $[-\epsilon, +\epsilon]$ in \mathbb{R} (or \mathbb{C}) form a line segment $[r, s]$ in A containing a , and that the image of this line segment defines a small curve segment on $f(A)$. This curve segment is defined by the map $t \mapsto f(a+tu)$, from $[r, s]$ to F , and the directional derivative $D_u f(a)$ defines the direction of the tangent line at a to this curve; see Figure 39.1. This leads us to the following definition.

Definition 39.2. Let E and F be two normed affine spaces, let A be a nonempty open subset of E , and let $f: A \rightarrow F$ be any function. For any $a \in A$, for any $u \neq 0$ in \vec{E} , the *directional derivative of f at a w.r.t. the vector u* , denoted by $D_u f(a)$, is the limit (if it exists)

$$\lim_{t \rightarrow 0, t \in U} \frac{f(a+tu) - f(a)}{t},$$

where $U = \{t \in \mathbb{R} \mid a+tu \in A, t \neq 0\}$ (or $U = \{t \in \mathbb{C} \mid a+tu \in A, t \neq 0\}$).

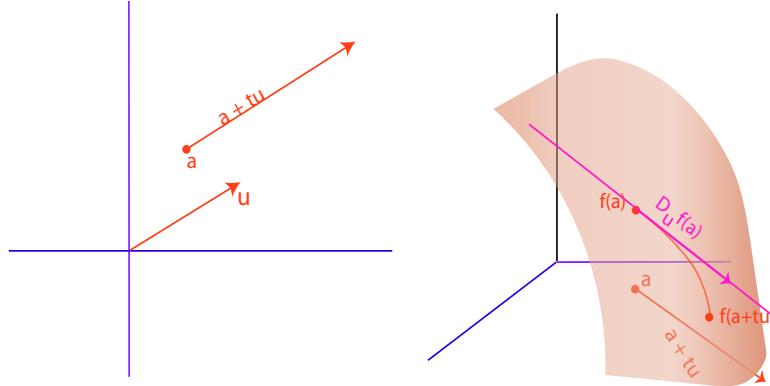

Figure 39.1: Let $f: \mathbb{R}^2 \rightarrow \mathbb{R}$. The graph of f is the peach surface in \mathbb{R}^3 , and $t \mapsto f(a + tu)$ is the embedded orange curve connecting $f(a)$ to $f(a + tu)$. Then $D_u f(a)$ is the slope of the pink tangent line in the direction of u .

Since the map $t \mapsto a + tu$ is continuous, and since $A - \{a\}$ is open, the inverse image U of $A - \{a\}$ under the above map is open, and the definition of the limit in Definition 39.2 makes sense.

Remark: Since the notion of limit is purely topological, the existence and value of a directional derivative is independent of the choice of norms in E and F , as long as they are equivalent norms.

The directional derivative is sometimes called the *Gâteaux derivative*.

In the special case where $E = \mathbb{R}$ and $F = \mathbb{R}$, and we let $u = 1$ (i.e., the real number 1, viewed as a vector), it is immediately verified that $D_1 f(a) = f'(a)$, in the sense of Definition 39.1. When $E = \mathbb{R}$ (or $E = \mathbb{C}$) and F is any normed vector space, the derivative $D_1 f(a)$, also denoted by $f'(a)$, provides a suitable generalization of the notion of derivative.

However, when E has dimension ≥ 2 , directional derivatives present a serious problem, which is that their definition is not sufficiently uniform. Indeed, there is no reason to believe that the directional derivatives w.r.t. all nonnull vectors u share something in common. As a consequence, a function can have all directional derivatives at a , and yet not be continuous at a . Two functions may have all directional derivatives in some open sets, and yet their composition may not.

Example 39.1. Let $f: \mathbb{R}^2 \rightarrow \mathbb{R}$ be the function given by

$$f(x, y) = \begin{cases} \frac{x^2 y}{x^4 + y^2} & \text{if } (x, y) \neq (0, 0) \\ 0 & \text{if } (x, y) = (0, 0). \end{cases}$$

The graph of $f(x, y)$ is illustrated in Figure 39.2.

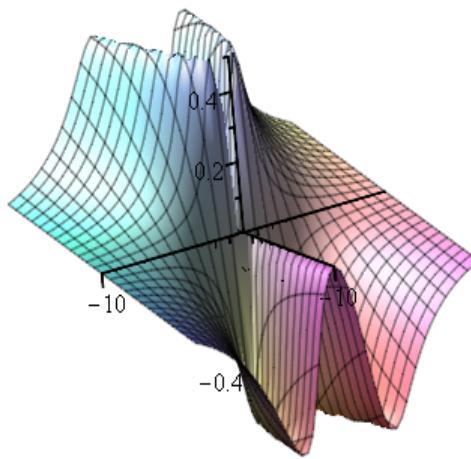

Figure 39.2: The graph of the function from Example 39.1. Note that f is not continuous at $(0, 0)$, despite the existence of $D_u f(0, 0)$ for all $u \neq 0$.

For any $u \neq 0$, letting $u = \begin{pmatrix} h \\ k \end{pmatrix}$, we have

$$\frac{f(0 + tu) - f(0)}{t} = \frac{h^2 k}{t^2 h^4 + k^2},$$

so that

$$D_u f(0, 0) = \begin{cases} \frac{h^2}{k} & \text{if } k \neq 0 \\ 0 & \text{if } k = 0. \end{cases}$$

Thus, $D_u f(0, 0)$ exists for all $u \neq 0$.

On the other hand, if $Df(0, 0)$ existed, it would be a linear map $Df(0, 0): \mathbb{R}^2 \rightarrow \mathbb{R}$ represented by a row matrix $(\alpha \ \beta)$, and we would have $D_u f(0, 0) = Df(0, 0)(u) = \alpha h + \beta k$, but the explicit formula for $D_u f(0, 0)$ is not linear. As a matter of fact, the function f is not continuous at $(0, 0)$. For example, on the parabola $y = x^2$, $f(x, y) = \frac{1}{2}$, and when we approach the origin on this parabola, the limit is $\frac{1}{2}$, but $f(0, 0) = 0$.

To avoid the problems arising with directional derivatives we introduce a more uniform notion.

Given two normed spaces E and F , recall that a linear map $f: E \rightarrow F$ is *continuous* iff there is some constant $C \geq 0$ such that

$$\|f(u)\| \leq C \|u\| \quad \text{for all } u \in E.$$

Definition 39.3. Let E and F be two normed affine spaces, let A be a nonempty open subset of E , and let $f: A \rightarrow F$ be any function. For any $a \in A$, we say that f is *differentiable at $a \in A$* if there is a linear continuous map $L: \overrightarrow{E} \rightarrow \overrightarrow{F}$ and a function ϵ , such that

$$f(a + h) = f(a) + L(h) + \epsilon(h)\|h\|$$

for every $a + h \in A$, where $\epsilon(h)$ is defined for every h such that $a + h \in A$ and

$$\lim_{h \rightarrow 0, h \in U} \epsilon(h) = 0,$$

where $U = \{h \in \overrightarrow{E} \mid a + h \in A, h \neq 0\}$. The linear map L is denoted by $Df(a)$, or Df_a , or $df(a)$, or df_a , or $f'(a)$, and it is called the *Fréchet derivative*, or *derivative*, or *total derivative*, or *total differential*, or *differential*, of f at a ; see Figure 39.3.

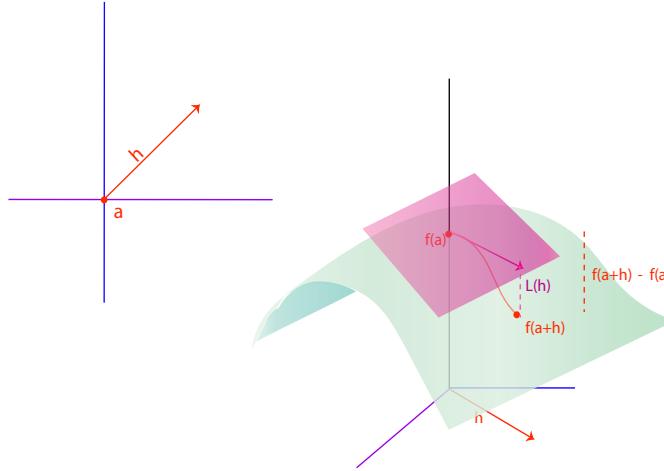

Figure 39.3: Let $f: \mathbb{R}^2 \rightarrow \mathbb{R}$. The graph of f is the green surface in \mathbb{R}^3 . The linear map $L = Df(a)$ is the pink tangent plane. For any vector $h \in \mathbb{R}^2$, $L(h)$ is approximately equal to $f(a + h) - f(a)$. Note that $L(h)$ is also the direction tangent to the curve $t \mapsto f(a + tu)$.

Since the map $h \mapsto a + h$ from \overrightarrow{E} to E is continuous, and since A is open in E , the inverse image U of $A - \{a\}$ under the above map is open in \overrightarrow{E} , and it makes sense to say that

$$\lim_{h \rightarrow 0, h \in U} \epsilon(h) = 0.$$

Note that for every $h \in U$, since $h \neq 0$, $\epsilon(h)$ is uniquely determined since

$$\epsilon(h) = \frac{f(a + h) - f(a) - L(h)}{\|h\|},$$

and that the value $\epsilon(0)$ plays absolutely no role in this definition. The condition for f to be differentiable at a amounts to the fact that

$$\lim_{h \rightarrow 0} \frac{\|f(a + h) - f(a) - L(h)\|}{\|h\|} = 0$$

as $h \neq 0$ approaches 0, when $a + h \in A$. However, it does no harm to assume that $\epsilon(0) = 0$, and we will assume this from now on.

Again, we note that the derivative $Df(a)$ of f at a provides an affine approximation of f , locally around a .

Remarks:

- (1) Since the notion of limit is purely topological, the existence and value of a derivative is independent of the choice of norms in E and F , as long as they are equivalent norms.
- (2) If $h: (-a, a) \rightarrow \mathbb{R}$ is a real-valued function defined on some open interval containing 0, we say that h is $o(t)$ for $t \rightarrow 0$, and we write $h(t) = o(t)$, if

$$\lim_{t \rightarrow 0, t \neq 0} \frac{h(t)}{t} = 0.$$

With this notation (the *little o notation*), the function f is differentiable at a iff

$$f(a + h) - f(a) - L(h) = o(\|h\|),$$

which is also written as

$$f(a + h) = f(a) + L(h) + o(\|h\|).$$

The following proposition shows that our new definition is consistent with the definition of the directional derivative and that *the continuous linear map L is unique*, if it exists.

Proposition 39.1. *Let E and F be two normed affine spaces, let A be a nonempty open subset of E , and let $f: A \rightarrow F$ be any function. For any $a \in A$, if $Df(a)$ is defined, then f is continuous at a and f has a directional derivative $D_u f(a)$ for every $u \neq 0$ in \overrightarrow{E} , and furthermore,*

$$D_u f(a) = Df(a)(u).$$

Proof. If $L = Df(a)$ exists, then for any nonzero vector $u \in \overrightarrow{E}$, because A is open, for any $t \in \mathbb{R} - \{0\}$ (or $t \in \mathbb{C} - \{0\}$) small enough, $a + tu \in A$, so

$$\begin{aligned} f(a + tu) &= f(a) + L(tu) + \epsilon(tu)\|tu\| \\ &= f(a) + tL(u) + |t|\epsilon(tu)\|u\| \end{aligned}$$

which implies that

$$L(u) = \frac{f(a + tu) - f(a)}{t} - \frac{|t|}{t} \epsilon(tu) \|u\|,$$

and since $\lim_{t \rightarrow 0} \epsilon(tu) = 0$, we deduce that

$$L(u) = Df(a)(u) = D_u f(a).$$

Because

$$f(a + h) = f(a) + L(h) + \epsilon(h) \|h\|$$

for all h such that $\|h\|$ is small enough, L is continuous, and $\lim_{h \rightarrow 0} \epsilon(h) \|h\| = 0$, we have $\lim_{h \rightarrow 0} f(a + h) = f(a)$, that is, f is continuous at a . \square

When E is of finite dimension, every linear map is continuous (see Proposition 9.8 or Theorem 37.58), and this assumption is then redundant.

It is important to note that the derivative $Df(a)$ of f at a is a continuous linear map from the *vector space* \vec{E} to the *vector space* \vec{F} , and not a function from the affine space E to the affine space F .

Although this may not be immediately obvious, the reason for requiring the linear map Df_a to be continuous is to ensure that if a function f is differentiable at a , then it is continuous at a . This is certainly a desirable property of a differentiable function. In finite dimension this holds, but in infinite dimension this is not the case. The following proposition shows that if Df_a exists at a and if f is continuous at a , then Df_a must be a continuous map. So if a function is differentiable at a , then it is continuous iff the linear map Df_a is continuous. We chose to include the second condition rather than the first in the definition of a differentiable function.

Proposition 39.2. *Let E and F be two normed affine spaces, let A be a nonempty open subset of E , and let $f: A \rightarrow F$ be any function. For any $a \in A$, if Df_a is defined, then f is continuous at a iff Df_a is a continuous linear map.*

Proof. Proposition 39.1 shows that if Df_a is defined and continuous then f is continuous at a . Conversely, assume that Df_a exists and that f is continuous at a . Since f is continuous at a and since Df_a exists, for any $\eta > 0$ there is some ρ with $0 < \rho < 1$ such that if $\|h\| \leq \rho$ then

$$\|f(a + h) - f(a)\| \leq \frac{\eta}{2},$$

and

$$\|f(a + h) - f(a) - D_a(h)\| \leq \frac{\eta}{2} \|h\| \leq \frac{\eta}{2},$$

so we have

$$\begin{aligned} \|D_a(h)\| &= \|D_a(h) - (f(a + h) - f(a)) + f(a + h) - f(a)\| \\ &\leq \|f(a + h) - f(a) - D_a(h)\| + \|f(a + h) - f(a)\| \\ &\leq \frac{\eta}{2} + \frac{\eta}{2} = \eta, \end{aligned}$$

which proves that Df_a is continuous at 0. By Proposition 37.56, Df_a is a continuous linear map. \square

Example 39.2. Consider the map, $f: M_n(\mathbb{R}) \rightarrow M_n(\mathbb{R})$, given by

$$f(A) = A^\top A - I,$$

where $M_n(\mathbb{R})$ is equipped with any matrix norm, since they are all equivalent; for example, pick the Frobenius norm, $\|A\|_F = \sqrt{\text{tr}(A^\top A)}$. We claim that

$$Df(A)(H) = A^\top H + H^\top A, \quad \text{for all } A \text{ and } H \text{ in } M_n(\mathbb{R}).$$

We have

$$\begin{aligned} f(A + H) - f(A) - (A^\top H + H^\top A) &= (A + H)^\top (A + H) - I - (A^\top A - I) - A^\top H - H^\top A \\ &= A^\top A + A^\top H + H^\top A + H^\top H - A^\top A - A^\top H - H^\top A \\ &= H^\top H. \end{aligned}$$

It follows that

$$\epsilon(H) = \frac{f(A + H) - f(A) - (A^\top H + H^\top A)}{\|H\|} = \frac{H^\top H}{\|H\|},$$

and since our norm is the Frobenius norm,

$$\|\epsilon(H)\| = \left\| \frac{H^\top H}{\|H\|} \right\| \leq \frac{\|H^\top\| \|H\|}{\|H\|} = \|H^\top\| = \|H\|,$$

so

$$\lim_{H \rightarrow 0} \epsilon(H) = 0,$$

and we conclude that

$$Df(A)(H) = A^\top H + H^\top A.$$

If $Df(a)$ exists for every $a \in A$, we get a map

$$Df: A \rightarrow \mathcal{L}(\overrightarrow{E}; \overrightarrow{F}),$$

called the *derivative of f on A* , and also denoted by df . Recall that $\mathcal{L}(\overrightarrow{E}; \overrightarrow{F})$ denotes the vector space of all continuous maps from \overrightarrow{E} to \overrightarrow{F} .

We now consider a number of standard results about derivatives.

39.2 Properties of Derivatives

Proposition 39.3. *Given two normed affine spaces E and F , if $f: E \rightarrow F$ is a constant function, then $Df(a) = 0$, for every $a \in E$. If $f: E \rightarrow F$ is a continuous affine map, then $Df(a) = \overrightarrow{f}$, for every $a \in E$, the linear map associated with f .*

Proof. Straightforward. \square

Proposition 39.4. *Given a normed affine space E and a normed vector space F , for any two functions $f, g: E \rightarrow F$, for every $a \in E$, if $Df(a)$ and $Dg(a)$ exist, then $D(f+g)(a)$ and $D(\lambda f)(a)$ exist, and*

$$\begin{aligned} D(f+g)(a) &= Df(a) + Dg(a), \\ D(\lambda f)(a) &= \lambda Df(a). \end{aligned}$$

Proof. Straightforward. \square

Given two normed vector spaces $(E_1, \| \cdot \|_1)$ and $(E_2, \| \cdot \|_2)$, there are three natural and equivalent norms that can be used to make $E_1 \times E_2$ into a normed vector space:

1. $\|(u_1, u_2)\|_1 = \|u_1\|_1 + \|u_2\|_2$.
2. $\|(u_1, u_2)\|_2 = (\|u_1\|_1^2 + \|u_2\|_2^2)^{1/2}$.
3. $\|(u_1, u_2)\|_\infty = \max(\|u_1\|_1, \|u_2\|_2)$.

We usually pick the first norm. If E_1 , E_2 , and F are three normed vector spaces, recall that a bilinear map $f: E_1 \times E_2 \rightarrow F$ is *continuous* iff there is some constant $C \geq 0$ such that

$$\|f(u_1, u_2)\| \leq C \|u_1\|_1 \|u_2\|_2 \quad \text{for all } u_1 \in E_1 \text{ and all } u_2 \in E_2.$$

Proposition 39.5. *Given three normed vector spaces E_1 , E_2 , and F , for any continuous bilinear map $f: E_1 \times E_2 \rightarrow F$, for every $(a, b) \in E_1 \times E_2$, $Df(a, b)$ exists, and for every $u \in E_1$ and $v \in E_2$,*

$$Df(a, b)(u, v) = f(u, b) + f(a, v).$$

Proof. Since f is bilinear, a simple computation implies that

$$\begin{aligned} f((a, b) + (u, v)) - f(a, b) - (f(u, b) + f(a, v)) &= f(a + u, b + v) - f(a, b) - f(u, b) - f(a, v) \\ &= f(a + u, b) + f(a + u, v) - f(a, b) - f(u, b) - f(a, v) \\ &= f(a, b) + f(u, b) + f(a, v) + f(u, v) - f(a, b) - f(u, b) - f(a, v) \\ &= f(u, v). \end{aligned}$$

We define

$$\epsilon(u, v) = \frac{f((a, b) + (u, v)) - f(a, b) - (f(u, b) + f(a, v))}{\|(u, v)\|_1},$$

and observe that the continuity of f implies

$$\begin{aligned} \|f((a, b) + (u, v)) - f(a, b) - (f(u, b) + f(a, v))\| &= \|f(u, v)\| \\ &\leq C \|u\|_1 \|v\|_2 \leq C (\|u\|_1 + \|v\|_2)^2. \end{aligned}$$

Hence

$$\|\epsilon(u, v)\| = \left\| \frac{f(u, v)}{\|(u, v)\|_1} \right\| = \frac{\|f(u, v)\|}{\|(u, v)\|_1} \leq \frac{C (\|u\|_1 + \|v\|_2)^2}{\|u\|_1 + \|v\|_2} = C (\|u\|_1 + \|v\|_2) = C \|(u, v)\|_1,$$

which in turn implies

$$\lim_{(u,v) \rightarrow (0,0)} \epsilon(u, v) = 0.$$

□

We now state the very useful *chain rule*.

Theorem 39.6. *Given three normed affine spaces E , F , and G , let A be an open set in E , and let B an open set in F . For any functions $f: A \rightarrow F$ and $g: B \rightarrow G$, such that $f(A) \subseteq B$, for any $a \in A$, if $Df(a)$ exists and $Dg(f(a))$ exists, then $D(g \circ f)(a)$ exists, and*

$$D(g \circ f)(a) = Dg(f(a)) \circ Df(a).$$

Proof. Since f is differentiable at a and g is differentiable at $b = f(a)$ for every η such that $0 < \eta < 1$ there is some $\rho > 0$ such that for all s, t , if $\|s\| \leq \rho$ and $\|t\| \leq \rho$ then

$$\begin{aligned} f(a + s) &= f(a) + Df_a(s) + \epsilon_1(s) \\ g(b + t) &= g(b) + Dg_b(t) + \epsilon_2(t), \end{aligned}$$

with $\|\epsilon_1(s)\| \leq \eta \|s\|$ and $\|\epsilon_2(t)\| \leq \eta \|t\|$. Since Df_a and Dg_b are continuous, we have

$$\|Df_a(s)\| \leq \|Df_a\| \|s\| \quad \text{and} \quad \|Dg_b(t)\| \leq \|Dg_b\| \|t\|,$$

which, since $\|\epsilon_1(s)\| \leq \eta \|s\|$ and $\eta < 1$, implies that

$$\|Df_a(s) + \epsilon_1(s)\| \leq \|Df_a\| \|s\| + \|\epsilon_1(s)\| \leq \|Df_a\| \|s\| + \eta \|s\| \leq (\|Df_a\| + 1) \|s\|.$$

Consequently, if $\|s\| < \rho/(\|Df_a\| + 1)$, we have

$$\|\epsilon_2(Df_a(s) + \epsilon_1(s))\| \leq \eta (\|Df_a\| + 1) \|s\| \tag{*}_1$$

and

$$\|Dg_b(\epsilon_1(s))\| \leq \|Dg_b\| \|\epsilon_1(s)\| \leq \eta \|Dg_b\| \|s\|. \tag{*}_2$$

Then since $b = f(a)$, using the above we have

$$\begin{aligned}(g \circ f)(a + s) &= g(f(a + s)) = g(b + Df_a(s) + \epsilon_1(s)) \\ &= g(b) + Dg_b(Df_a(s) + \epsilon_1(s)) + \epsilon_2(Df_a(s) + \epsilon_1(s)) \\ &= g(b) + (Dg_b \circ Df_a)(s) + Dg_b(\epsilon_1(s)) + \epsilon_2(Df_a(s) + \epsilon_1(s)).\end{aligned}$$

Now by $(*_1)$ and $(*_2)$ we have

$$\begin{aligned}\|Dg_b(\epsilon_1(s)) + \epsilon_2(Df_a(s) + \epsilon_1(s))\| &\leq \|Dg_b(\epsilon_1(s))\| + \|\epsilon_2(Df_a(s) + \epsilon_1(s))\| \\ &\leq \eta \|Dg_b\| \|s\| + \eta (\|Df_a\| + 1) \|s\| \\ &= \eta (\|Df_a\| + \|Dg_b\| + 1) \|s\|,\end{aligned}$$

so if we write $\epsilon_3(s) = Dg_b(\epsilon_1(s)) + \epsilon_2(Df_a(s) + \epsilon_1(s))$ we proved that

$$(g \circ f)(a + s) = g(b) + (Dg_b \circ Df_a)(s) + \epsilon_3(s)$$

with $\epsilon_3(s) \leq \eta (\|Df_a\| + \|Dg_b\| + 1) \|s\|$, which proves that $Dg_b \circ Df_a$ is the derivative of $g \circ f$ at a . Since Df_a and Dg_b are continuous, so is $Dg_b \circ Df_a$, which proves our proposition. \square

Theorem 39.6 has many interesting consequences. We mention two corollaries.

Proposition 39.7. *Given three normed affine spaces E , F , and G , for any open subset A in E , for any $a \in A$, let $f: A \rightarrow F$ such that $Df(a)$ exists, and let $g: F \rightarrow G$ be a continuous affine map. Then, $D(g \circ f)(a)$ exists, and*

$$D(g \circ f)(a) = \overrightarrow{g} \circ Df(a),$$

where \overrightarrow{g} is the linear map associated with the affine map g .

Proposition 39.8. *Given two normed affine spaces E and F , let A be some open subset in E , let B be some open subset in F , let $f: A \rightarrow B$ be a bijection from A to B , and assume that Df exists on A and that Df^{-1} exists on B . Then, for every $a \in A$,*

$$Df^{-1}(f(a)) = (Df(a))^{-1}.$$

Proposition 39.8 has the remarkable consequence that the two vector spaces \vec{E} and \vec{F} have the same dimension. In other words, a local property, the existence of a bijection f between an open set A of E and an open set B of F , such that f is differentiable on A and f^{-1} is differentiable on B , implies a global property, that the two vector spaces \vec{E} and \vec{F} have the same dimension.

Let us mention two more rules about derivatives that are used all the time.

Let $\iota: \mathbf{GL}(n, \mathbb{C}) \rightarrow M_n(\mathbb{C})$ be the function (inversion) defined on invertible $n \times n$ matrices by

$$\iota(A) = A^{-1}.$$

Observe that $\mathbf{GL}(n, \mathbb{C})$ is indeed an open subset of the normed vector space $M_n(\mathbb{C})$ of complex $n \times n$ matrices, since its complement is the closed set of matrices $A \in M_n(\mathbb{C})$ satisfying $\det(A) = 0$. Then we have

$$d\iota_A(H) = -A^{-1}HA^{-1},$$

for all $A \in \mathbf{GL}(n, \mathbb{C})$ and for all $H \in M_n(\mathbb{C})$.

To prove the preceding line observe that for H with sufficiently small norm, we have

$$\begin{aligned} \iota(A + H) - \iota(A) + A^{-1}HA^{-1} &= (A + H)^{-1} - A^{-1} + A^{-1}HA^{-1} \\ &= (A + H)^{-1}[I - (A + H)A^{-1} + (A + H)A^{-1}HA^{-1}] \\ &= (A + H)^{-1}[I - I - HA^{-1} + HA^{-1} + HA^{-1}HA^{-1}] \\ &= (A + H)^{-1}HA^{-1}HA^{-1}. \end{aligned}$$

Consequently, we get

$$\epsilon(H) = \frac{\iota(A + H) - \iota(A) + A^{-1}HA^{-1}}{\|H\|} = \frac{(A + H)^{-1}HA^{-1}HA^{-1}}{\|H\|},$$

and since

$$\|(A + H)^{-1}HA^{-1}HA^{-1}\| \leq \|H\|^2 \|A^{-1}\|^2 \|(A + H)^{-1}\|,$$

it is clear that $\lim_{H \rightarrow 0} \epsilon(H) = 0$, which proves that

$$d\iota_A(H) = -A^{-1}HA^{-1}.$$

In particular, if $A = I$, then $d\iota_I(H) = -H$.

Next, if $f: M_n(\mathbb{C}) \rightarrow M_n(\mathbb{C})$ and $g: M_n(\mathbb{C}) \rightarrow M_n(\mathbb{C})$ are differentiable matrix functions, then

$$d(fg)_A(B) = df_A(B)g(A) + f(A)dg_A(B),$$

for all $A, B \in M_n(\mathbb{C})$. This is known as the *product rule*.

When E is of finite dimension n , for any frame $(a_0, (u_1, \dots, u_n))$ of E , where (u_1, \dots, u_n) is a basis of \overrightarrow{E} , we can define the directional derivatives with respect to the vectors in the basis (u_1, \dots, u_n) (actually, we can also do it for an infinite frame). This way, we obtain the definition of partial derivatives, as follows.

Definition 39.4. For any two normed affine spaces E and F , if E is of finite dimension n , for every frame $(a_0, (u_1, \dots, u_n))$ for E , for every $a \in E$, for every function $f: E \rightarrow F$, the directional derivatives $D_{u_j}f(a)$ (if they exist) are called the *partial derivatives of f with respect to the frame $(a_0, (u_1, \dots, u_n))$* . The partial derivative $D_{u_j}f(a)$ is also denoted by $\partial_j f(a)$, or $\frac{\partial f}{\partial x_j}(a)$.

The notation $\frac{\partial f}{\partial x_j}(a)$ for a partial derivative, although customary and going back to Leibniz, is a “logical obscenity.” Indeed, the variable x_j really has nothing to do with the formal definition. This is just another of these situations where tradition is just too hard to overthrow!

We now consider the situation where the normed affine space F is a finite direct sum $F = (F_1, b_1) \oplus \cdots \oplus (F_m, b_m)$.

Proposition 39.9. *Given normed affine spaces E and $F = (F_1, b_1) \oplus \cdots \oplus (F_m, b_m)$, given any open subset A of E , for any $a \in A$, for any function $f: A \rightarrow F$, letting $f = (f_1, \dots, f_m)$, $Df(a)$ exists iff every $Df_i(a)$ exists, and*

$$Df(a) = i n_1 \circ Df_1(a) + \cdots + i n_m \circ Df_m(a).$$

Proof. Observe that $f(a + h) - f(a) = (f(a + h) - b) - (f(a) - b)$, where $b = (b_1, \dots, b_m)$, and thus, as far as dealing with derivatives, $Df(a)$ is equal to $Df_b(a)$, where $f_b: E \rightarrow \vec{F}$ is defined such that $f_b(x) = f(x) - b$, for every $x \in E$. Thus, we can work with the vector space \vec{F} instead of the affine space F . The proposition is then a simple application of Theorem 39.6. \square

In the special case where F is a normed affine space of finite dimension m , for any frame $(b_0, (v_1, \dots, v_m))$ of F , where (v_1, \dots, v_m) is a basis of \vec{F} , every point $x \in F$ can be expressed uniquely as

$$x = b_0 + x_1 v_1 + \cdots + x_m v_m,$$

where $(x_1, \dots, x_m) \in K^m$, the coordinates of x in the frame $(b_0, (v_1, \dots, v_m))$ (where $K = \mathbb{R}$ or $K = \mathbb{C}$). Thus, letting F_i be the standard normed affine space K with its natural structure, we note that F is isomorphic to the direct sum $F = (K, 0) \oplus \cdots \oplus (K, 0)$. Then, every function $f: E \rightarrow F$ is represented by m functions (f_1, \dots, f_m) , where $f_i: E \rightarrow K$ (where $K = \mathbb{R}$ or $K = \mathbb{C}$), and

$$f(x) = b_0 + f_1(x)v_1 + \cdots + f_m(x)v_m,$$

for every $x \in E$. The following proposition is an immediate corollary of Proposition 39.9.

Proposition 39.10. *For any two normed affine spaces E and F , if F is of finite dimension m , for any frame $(b_0, (v_1, \dots, v_m))$ of F , where (v_1, \dots, v_m) is a basis of \vec{F} , for every $a \in E$, a function $f: E \rightarrow F$ is differentiable at a iff each f_i is differentiable at a , and*

$$Df(a)(u) = Df_1(a)(u)v_1 + \cdots + Df_m(a)(u)v_m,$$

for every $u \in \vec{E}$.

We now consider the situation where E is a finite direct sum. Given a normed affine space $E = (E_1, a_1) \oplus \cdots \oplus (E_n, a_n)$ and a normed affine space F , given any open subset A of E , for any $c = (c_1, \dots, c_n) \in A$, we define the continuous functions $i_j^c: E_j \rightarrow E$, such that

$$i_j^c(x) = (c_1, \dots, c_{j-1}, x, c_{j+1}, \dots, c_n).$$

For any function $f: A \rightarrow F$, we have functions $f \circ i_j^c: E_j \rightarrow F$, defined on $(i_j^c)^{-1}(A)$, which contains c_j . If $D(f \circ i_j^c)(c_j)$ exists, we call it the *partial derivative of f w.r.t. its j th argument, at c* . We also denote this derivative by $D_j f(c)$. Note that $D_j f(c) \in \mathcal{L}(\overrightarrow{E_j}; \overrightarrow{F})$.

This notion is a generalization of the notion defined in Definition 39.4. In fact, when E is of dimension n , and a frame $(a_0, (u_1, \dots, u_n))$ has been chosen, we can write $E = (E_1, a_1) \oplus \cdots \oplus (E_n, a_n)$, for some obvious (E_j, a_j) (as explained just after Proposition 39.9), and then

$$D_j f(c)(\lambda u_j) = \lambda \partial_j f(c),$$

and the two notions are consistent.

The definition of i_j^c and of $D_j f(c)$ also makes sense for a finite product $E_1 \times \cdots \times E_n$ of affine spaces E_i . We will use freely the notation $\partial_j f(c)$ instead of $D_j f(c)$.

The notion $\partial_j f(c)$ introduced in Definition 39.4 is really that of the vector derivative, whereas $D_j f(c)$ is the corresponding linear map. Although perhaps confusing, we identify the two notions. The following proposition holds.

Proposition 39.11. *Given a normed affine space $E = (E_1, a_1) \oplus \cdots \oplus (E_n, a_n)$, and a normed affine space F , given any open subset A of E , for any function $f: A \rightarrow F$, for every $c \in A$, if $Df(c)$ exists, then each $D_j f(c)$ exists, and*

$$Df(c)(u_1, \dots, u_n) = D_1 f(c)(u_1) + \cdots + D_n f(c)(u_n),$$

for every $u_i \in E_i$, $1 \leq i \leq n$. The same result holds for the finite product $E_1 \times \cdots \times E_n$.

Proof. Since every $c \in E$ can be written as $c = a + c - a$, where $a = (a_1, \dots, a_n)$, defining $f_a: \overrightarrow{E} \rightarrow F$ such that, $f_a(u) = f(a + u)$, for every $u \in \overrightarrow{E}$, clearly, $Df(c) = Df_a(c - a)$, and thus, we can work with the function f_a whose domain is the vector space \overrightarrow{E} . The proposition is then a simple application of Theorem 39.6. \square

39.3 Jacobian Matrices

If both E and F are of finite dimension, for any frame $(a_0, (u_1, \dots, u_n))$ of E and any frame $(b_0, (v_1, \dots, v_m))$ of F , every function $f: E \rightarrow F$ is determined by m functions $f_i: E \rightarrow \mathbb{R}$ (or $f_i: E \rightarrow \mathbb{C}$), where

$$f(x) = b_0 + f_1(x)v_1 + \cdots + f_m(x)v_m,$$

for every $x \in E$. From Proposition 39.1, we have

$$Df(a)(u_j) = D_{u_j}f(a) = \partial_j f(a),$$

and from Proposition 39.10, we have

$$Df(a)(u_j) = Df_1(a)(u_j)v_1 + \cdots + Df_i(a)(u_j)v_i + \cdots + Df_m(a)(u_j)v_m,$$

that is,

$$Df(a)(u_j) = \partial_j f_1(a)v_1 + \cdots + \partial_j f_i(a)v_i + \cdots + \partial_j f_m(a)v_m.$$

Since the j -th column of the $m \times n$ -matrix representing $Df(a)$ w.r.t. the bases (u_1, \dots, u_n) and (v_1, \dots, v_m) is equal to the components of the vector $Df(a)(u_j)$ over the basis (v_1, \dots, v_m) , the linear map $Df(a)$ is determined by the $m \times n$ -matrix $J(f)(a) = (\partial_j f_i(a))$, (or $J(f)(a) = (\frac{\partial f_i}{\partial x_j}(a))$):

$$J(f)(a) = \begin{pmatrix} \partial_1 f_1(a) & \partial_2 f_1(a) & \dots & \partial_n f_1(a) \\ \partial_1 f_2(a) & \partial_2 f_2(a) & \dots & \partial_n f_2(a) \\ \vdots & \vdots & \ddots & \vdots \\ \partial_1 f_m(a) & \partial_2 f_m(a) & \dots & \partial_n f_m(a) \end{pmatrix}$$

or

$$J(f)(a) = \begin{pmatrix} \frac{\partial f_1}{\partial x_1}(a) & \frac{\partial f_1}{\partial x_2}(a) & \dots & \frac{\partial f_1}{\partial x_n}(a) \\ \frac{\partial f_2}{\partial x_1}(a) & \frac{\partial f_2}{\partial x_2}(a) & \dots & \frac{\partial f_2}{\partial x_n}(a) \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial f_m}{\partial x_1}(a) & \frac{\partial f_m}{\partial x_2}(a) & \dots & \frac{\partial f_m}{\partial x_n}(a) \end{pmatrix}$$

Definition 39.5. The matrix $J(f)(a)$ is called the *Jacobian matrix* of Df at a . When $m = n$, the determinant, $\det(J(f)(a))$, of $J(f)(a)$ is called the *Jacobian* of $Df(a)$.

From a previous result, we know that this determinant in fact only depends on $Df(a)$, and not on specific bases. However, partial derivatives give a means for computing it.

When $E = \mathbb{R}^n$ and $F = \mathbb{R}^m$, for any function $f: \mathbb{R}^n \rightarrow \mathbb{R}^m$, it is easy to compute the partial derivatives $\frac{\partial f_i}{\partial x_j}(a)$. We simply treat the function $f_i: \mathbb{R}^n \rightarrow \mathbb{R}$ as a function of its j -th argument, leaving the others fixed, and compute the derivative as in Definition 39.1, that is, the usual derivative.

Example 39.3. For example, consider the function $f: \mathbb{R}^2 \rightarrow \mathbb{R}^2$, defined such that

$$f(r, \theta) = (r \cos(\theta), r \sin(\theta)).$$

Then, we have

$$J(f)(r, \theta) = \begin{pmatrix} \cos(\theta) & -r \sin(\theta) \\ \sin(\theta) & r \cos(\theta) \end{pmatrix}$$

and the Jacobian (determinant) has value $\det(J(f)(r, \theta)) = r$.

In the case where $E = \mathbb{R}$ (or $E = \mathbb{C}$), for any function $f: \mathbb{R} \rightarrow F$ (or $f: \mathbb{C} \rightarrow F$), the Jacobian matrix of $Df(a)$ is a column vector. In fact, this column vector is just $D_1 f(a)$. Then, for every $\lambda \in \mathbb{R}$ (or $\lambda \in \mathbb{C}$),

$$Df(a)(\lambda) = \lambda D_1 f(a).$$

This case is sufficiently important to warrant a definition.

Definition 39.6. Given a function $f: \mathbb{R} \rightarrow F$ (or $f: \mathbb{C} \rightarrow F$), where F is a normed affine space, the vector

$$Df(a)(1) = D_1 f(a)$$

is called the *vector derivative or velocity vector (in the real case)* at a . We usually identify $Df(a)$ with its Jacobian matrix $D_1 f(a)$, which is the column vector corresponding to $D_1 f(a)$. By abuse of notation, we also let $Df(a)$ denote the vector $Df(a)(1) = D_1 f(a)$.

When $E = \mathbb{R}$, the physical interpretation is that f defines a (parametric) curve that is the trajectory of some particle moving in \mathbb{R}^m as a function of time, and the vector $D_1 f(a)$ is the *velocity* of the moving particle $f(t)$ at $t = a$.

It is often useful to consider functions $f: [a, b] \rightarrow F$ from a closed interval $[a, b] \subseteq \mathbb{R}$ to a normed affine space F , and its derivative $Df(a)$ on $[a, b]$, even though $[a, b]$ is not open. In this case, as in the case of a real-valued function, we define the right derivative $D_1 f(a_+)$ at a , and the left derivative $D_1 f(b_-)$ at b , and we assume their existence.

Example 39.4.

- When $A = (0, 1)$ and $F = \mathbb{R}^3$, a function

$f: (0, 1) \rightarrow \mathbb{R}^3$ defines a (parametric) curve in \mathbb{R}^3 . If $f = (f_1, f_2, f_3)$, its Jacobian matrix at $a \in \mathbb{R}$ is

$$J(f)(a) = \begin{pmatrix} \frac{\partial f_1}{\partial t}(a) \\ \frac{\partial f_2}{\partial t}(a) \\ \frac{\partial f_3}{\partial t}(a) \end{pmatrix}.$$

See Figure 39.4.

The velocity vectors $J(f)(a) = \begin{pmatrix} -\sin(t) \\ \cos(t) \\ 1 \end{pmatrix}$ are represented by the blue arrows.

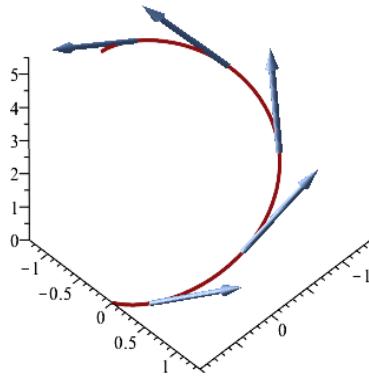

Figure 39.4: The red space curve $f(t) = (\cos(t), \sin(t), t)$.

2. When $E = \mathbb{R}^2$ and $F = \mathbb{R}^3$, a function $\varphi: \mathbb{R}^2 \rightarrow \mathbb{R}^3$ defines a parametric surface. Letting $\varphi = (f, g, h)$, its Jacobian matrix at $a \in \mathbb{R}^2$ is

$$J(\varphi)(a) = \begin{pmatrix} \frac{\partial f}{\partial u}(a) & \frac{\partial f}{\partial v}(a) \\ \frac{\partial g}{\partial u}(a) & \frac{\partial g}{\partial v}(a) \\ \frac{\partial h}{\partial u}(a) & \frac{\partial h}{\partial v}(a) \end{pmatrix}.$$

See Figure 39.5. The Jacobian matrix is $J(f)(a) = \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 2u & 2v \end{pmatrix}$. The first column is the vector tangent to the pink u -direction curve, while the second column is the vector tangent to the blue v -direction curve.

3. When $E = \mathbb{R}^3$ and $F = \mathbb{R}$, for a function $f: \mathbb{R}^3 \rightarrow \mathbb{R}$, the Jacobian matrix at $a \in \mathbb{R}^3$ is

$$J(f)(a) = \left(\frac{\partial f}{\partial x}(a) \quad \frac{\partial f}{\partial y}(a) \quad \frac{\partial f}{\partial z}(a) \right).$$

More generally, when $f: \mathbb{R}^n \rightarrow \mathbb{R}$, the Jacobian matrix at $a \in \mathbb{R}^n$ is the row vector

$$J(f)(a) = \left(\frac{\partial f}{\partial x_1}(a) \cdots \frac{\partial f}{\partial x_n}(a) \right).$$

Its transpose is a column vector called the *gradient* of f at a , denoted by $\text{grad}f(a)$ or $\nabla f(a)$. Then, given any $v \in \mathbb{R}^n$, note that

$$Df(a)(v) = \frac{\partial f}{\partial x_1}(a) v_1 + \cdots + \frac{\partial f}{\partial x_n}(a) v_n = \text{grad}f(a) \cdot v,$$

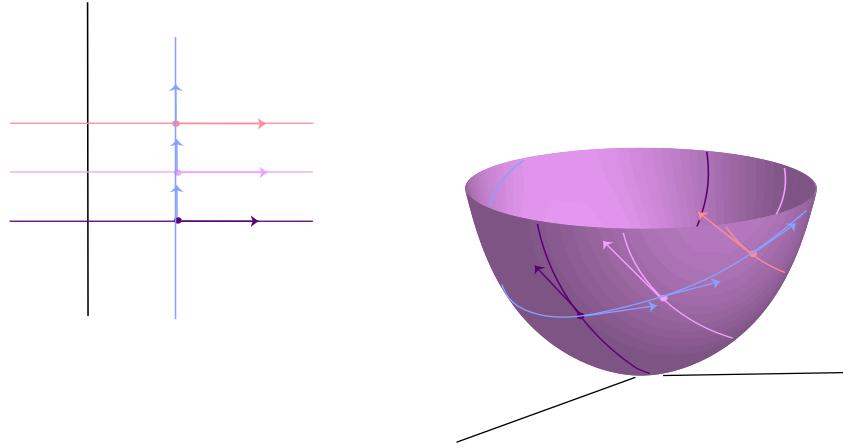

Figure 39.5: The parametric surface $x = u, y = v, z = u^2 + v^2$.

the scalar product of $\text{grad}f(a)$ and v .

Example 39.5. Consider the quadratic function $f: \mathbb{R}^n \rightarrow \mathbb{R}$ given by

$$f(x) = x^\top Ax, \quad x \in \mathbb{R}^n,$$

where A is a real $n \times n$ symmetric matrix. We claim that

$$df_u(h) = 2u^\top Ah \quad \text{for all } u, h \in \mathbb{R}^n.$$

Since A is symmetric, we have

$$\begin{aligned} f(u+h) &= (u^\top + h^\top)A(u+h) \\ &= u^\top Au + u^\top Ah + h^\top Au + h^\top Ah \\ &= u^\top Au + 2u^\top Ah + h^\top Ah, \end{aligned}$$

so we have

$$f(u+h) - f(u) - 2u^\top Ah = h^\top Ah.$$

If we write

$$\epsilon(h) = \frac{h^\top Ah}{\|h\|}$$

for $h \neq 0$ where $\|\cdot\|$ is the 2-norm, by Cauchy–Schwarz we have

$$|\epsilon(h)| \leq \frac{\|h\| \|Ah\|}{\|h\|} \leq \frac{\|h\|^2 \|A\|}{\|h\|} = \|h\| \|A\|,$$

which shows that $\lim_{h \rightarrow 0} \epsilon(h) = 0$. Therefore,

$$df_u(h) = 2u^\top Ah \quad \text{for all } u, h \in \mathbb{R}^n,$$

as claimed. This formula shows that the gradient ∇f_u of f at u is given by

$$\nabla f_u = 2Au.$$

As a first corollary we obtain the gradient of a function of the form

$$f(x) = \frac{1}{2}x^\top Ax - b^\top x,$$

where A is a symmetric $n \times n$ matrix and b is some vector $b \in \mathbb{R}^n$. Since the derivative of a linear function is itself, we obtain

$$df_u(h) = u^\top Ah - b^\top h,$$

and the gradient of f is given by

$$\nabla f_u = Au - b.$$

As a second corollary we obtain the gradient of the function

$$f(x) = \|Ax - b\|_2^2 = (Ax - b)^\top (Ax - b) = (x^\top A^\top - b^\top)(Ax - b)$$

which is the function to minimize in a least squares problem, where A is an $m \times n$ matrix. We have

$$f(x) = x^\top A^\top Ax - x^\top A^\top b - b^\top Ax + b^\top b = x^\top A^\top Ax - 2b^\top Ax + b^\top b,$$

and since the derivative of a constant function is 0 and the derivative of a linear function is itself, we get

$$df_u(h) = 2u^\top A^\top Ah - 2b^\top Ah.$$

Consequently, the gradient of f is given by

$$\nabla f_u = 2A^\top Au - 2A^\top b.$$

When E , F , and G have finite dimensions, and $(a_0, (u_1, \dots, u_p))$ is an affine frame for E , $(b_0, (v_1, \dots, v_n))$ is an affine frame for F , and $(c_0, (w_1, \dots, w_m))$ is an affine frame for G , if A is an open subset of E , B is an open subset of F , for any functions $f: A \rightarrow F$ and $g: B \rightarrow G$, such that $f(A) \subseteq B$, for any $a \in A$, letting $b = f(a)$, and $h = g \circ f$, if $Df(a)$ exists and $Dg(b)$ exists, by Theorem 39.6, the Jacobian matrix $J(h)(a) = J(g \circ f)(a)$ w.r.t. the bases (u_1, \dots, u_p) and (w_1, \dots, w_m) is the product of the Jacobian matrices $J(g)(b)$ w.r.t. the bases (v_1, \dots, v_n) and (w_1, \dots, w_m) , and $J(f)(a)$ w.r.t. the bases (u_1, \dots, u_p) and (v_1, \dots, v_n) :

$$J(h)(a) = \begin{pmatrix} \partial_1 g_1(b) & \partial_2 g_1(b) & \dots & \partial_n g_1(b) \\ \partial_1 g_2(b) & \partial_2 g_2(b) & \dots & \partial_n g_2(b) \\ \vdots & \vdots & \ddots & \vdots \\ \partial_1 g_m(b) & \partial_2 g_m(b) & \dots & \partial_n g_m(b) \end{pmatrix} \begin{pmatrix} \partial_1 f_1(a) & \partial_2 f_1(a) & \dots & \partial_p f_1(a) \\ \partial_1 f_2(a) & \partial_2 f_2(a) & \dots & \partial_p f_2(a) \\ \vdots & \vdots & \ddots & \vdots \\ \partial_1 f_n(a) & \partial_2 f_n(a) & \dots & \partial_p f_n(a) \end{pmatrix}$$

or

$$J(h)(a) = \begin{pmatrix} \frac{\partial g_1}{\partial y_1}(b) & \frac{\partial g_1}{\partial y_2}(b) & \dots & \frac{\partial g_1}{\partial y_n}(b) \\ \frac{\partial g_2}{\partial y_1}(b) & \frac{\partial g_2}{\partial y_2}(b) & \dots & \frac{\partial g_2}{\partial y_n}(b) \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial g_m}{\partial y_1}(b) & \frac{\partial g_m}{\partial y_2}(b) & \dots & \frac{\partial g_m}{\partial y_n}(b) \end{pmatrix} \begin{pmatrix} \frac{\partial f_1}{\partial x_1}(a) & \frac{\partial f_1}{\partial x_2}(a) & \dots & \frac{\partial f_1}{\partial x_p}(a) \\ \frac{\partial f_2}{\partial x_1}(a) & \frac{\partial f_2}{\partial x_2}(a) & \dots & \frac{\partial f_2}{\partial x_p}(a) \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial f_n}{\partial x_1}(a) & \frac{\partial f_n}{\partial x_2}(a) & \dots & \frac{\partial f_n}{\partial x_p}(a) \end{pmatrix}.$$

Thus, we have the familiar formula

$$\frac{\partial h_i}{\partial x_j}(a) = \sum_{k=1}^{k=n} \frac{\partial g_i}{\partial y_k}(b) \frac{\partial f_k}{\partial x_j}(a).$$

Given two normed affine spaces E and F of finite dimension, given an open subset A of E , if a function $f: A \rightarrow F$ is differentiable at $a \in A$, then its Jacobian matrix is well defined.

One should be warned that the converse is false. There are functions such that all the partial derivatives exist at some $a \in A$, but yet, the function is not differentiable at a , and not even continuous at a . For example, consider the function $f: \mathbb{R}^2 \rightarrow \mathbb{R}$, defined such that $f(0, 0) = 0$, and

$$f(x, y) = \frac{x^2 y}{x^4 + y^2} \quad \text{if } (x, y) \neq (0, 0).$$

For any $u \neq 0$, letting $u = \begin{pmatrix} h \\ k \end{pmatrix}$, we have

$$\frac{f(0 + tu) - f(0)}{t} = \frac{h^2 k}{t^2 h^4 + k^2},$$

so that

$$D_u f(0, 0) = \begin{cases} \frac{h^2}{k} & \text{if } k \neq 0 \\ 0 & \text{if } k = 0. \end{cases}$$

Thus, $D_u f(0, 0)$ exists for all $u \neq 0$. On the other hand, if $Df(0, 0)$ existed, it would be a linear map $Df(0, 0): \mathbb{R}^2 \rightarrow \mathbb{R}$ represented by a row matrix $(\alpha \ \beta)$, and we would have $D_u f(0, 0) = Df(0, 0)(u) = \alpha h + \beta k$, but the explicit formula for $D_u f(0, 0)$ is not linear. As a matter of fact, the function f is not continuous at $(0, 0)$. For example, on the parabola $y = x^2$, $f(x, y) = \frac{1}{2}$, and when we approach the origin on this parabola, the limit is $\frac{1}{2}$, when in fact, $f(0, 0) = 0$.

However, there are sufficient conditions on the partial derivatives for $Df(a)$ to exist, namely, continuity of the partial derivatives.

If f is differentiable on A , then f defines a function $Df: A \rightarrow \mathcal{L}(\overrightarrow{E}; \overrightarrow{F})$. It turns out that the continuity of the partial derivatives on A is a necessary and sufficient condition for Df to exist and to be continuous on A .

If $f: [a, b] \rightarrow \mathbb{R}$ is a function which is continuous on $[a, b]$ and differentiable on (a, b) , then there is some c with $a < c < b$ such that

$$f(b) - f(a) = (b - a)f'(c).$$

This result is known as the *mean value theorem* and is a generalization of *Rolle's theorem*, which corresponds to the case where $f(a) = f(b)$.

Unfortunately, the mean value theorem fails for vector-valued functions. For example, the function $f: [0, 2\pi] \rightarrow \mathbb{R}^2$ given by

$$f(t) = (\cos t, \sin t)$$

is such that $f(2\pi) - f(0) = (0, 0)$, yet its derivative $f'(t) = (-\sin t, \cos t)$ does not vanish in $(0, 2\pi)$.

A suitable generalization of the mean value theorem to vector-valued functions is possible if we consider an inequality (an upper bound) instead of an equality. This generalized version of the mean value theorem plays an important role in the proof of several major results of differential calculus.

If E is an affine space (over \mathbb{R} or \mathbb{C}), given any two points $a, b \in E$, the *closed segment* $[a, b]$ is the set of all points $a + \lambda(b - a)$, where $0 \leq \lambda \leq 1$, $\lambda \in \mathbb{R}$, and the *open segment* (a, b) is the set of all points $a + \lambda(b - a)$, where $0 < \lambda < 1$, $\lambda \in \mathbb{R}$.

Proposition 39.12. *Let E and F be two normed affine spaces, let A be an open subset of E , and let $f: A \rightarrow F$ be a continuous function on A . Given any $a \in A$ and any $h \neq 0$ in \overrightarrow{E} , if the closed segment $[a, a + h]$ is contained in A , if $f: A \rightarrow F$ is differentiable at every point of the open segment $(a, a + h)$, and*

$$\sup_{x \in (a, a+h)} \|Df(x)\| \leq M,$$

for some $M \geq 0$, then

$$\|f(a + h) - f(a)\| \leq M\|h\|.$$

As a corollary, if $L: \overrightarrow{E} \rightarrow \overrightarrow{F}$ is a continuous linear map, then

$$\|f(a + h) - f(a) - L(h)\| \leq M\|h\|,$$

where $M = \sup_{x \in (a, a+h)} \|Df(x) - L\|$.

The above proposition is sometimes called the “mean value theorem.” Proposition 39.12 can be used to show the following important result.

Theorem 39.13. *Given two normed affine spaces E and F , where E is of finite dimension n , and where $(a_0, (u_1, \dots, u_n))$ is a frame of E , given any open subset A of E , given any function $f: A \rightarrow F$, the derivative $Df: A \rightarrow \mathcal{L}(\overrightarrow{E}; \overrightarrow{F})$ is defined and continuous on A iff every partial derivative $\partial_j f$ (or $\frac{\partial f}{\partial x_j}$) is defined and continuous on A , for all j , $1 \leq j \leq n$. As a corollary, if F is of finite dimension m , and $(b_0, (v_1, \dots, v_m))$ is a frame of F , the derivative $Df: A \rightarrow \mathcal{L}(\overrightarrow{E}; \overrightarrow{F})$ is defined and continuous on A iff every partial derivative $\partial_j f_i$ (or $\frac{\partial f_i}{\partial x_j}$) is defined and continuous on A , for all i, j , $1 \leq i \leq m$, $1 \leq j \leq n$.*

Theorem 39.13 gives a necessary and sufficient condition for the existence and continuity of the derivative of a function on an open set. It should be noted that a more general version of Theorem 39.13 holds, assuming that $E = (E_1, a_1) \oplus \dots \oplus (E_n, a_n)$, or $E = E_1 \times \dots \times E_n$, and using the more general partial derivatives $D_j f$ introduced before Proposition 39.11.

Definition 39.7. Given two normed affine spaces E and F , and an open subset A of E , we say that a function $f: A \rightarrow F$ is *of class C^0 on A or a C^0 -function on A* if f is continuous on A . We say that $f: A \rightarrow F$ is *of class C^1 on A or a C^1 -function on A* if Df exists and is continuous on A .

Since the existence of the derivative on an open set implies continuity, a C^1 -function is of course a C^0 -function. Theorem 39.13 gives a necessary and sufficient condition for a function f to be a C^1 -function (when E is of finite dimension). It is easy to show that the composition of C^1 -functions (on appropriate open sets) is a C^1 -function.

39.4 The Implicit and The Inverse Function Theorems

Given three normed affine spaces E , F , and G , given a function $f: E \times F \rightarrow G$, given any $c \in G$, it may happen that the equation

$$f(x, y) = c$$

has the property that, for some open sets $A \subseteq E$, and $B \subseteq F$, there is a function $g: A \rightarrow B$, such that

$$f(x, g(x)) = c,$$

for all $x \in A$. Such a situation is usually very rare, but if some solution $(a, b) \in E \times F$ such that $f(a, b) = c$ is known, under certain conditions, for some small open sets $A \subseteq E$ containing a and $B \subseteq F$ containing b , the existence of a unique $g: A \rightarrow B$, such that

$$f(x, g(x)) = c,$$

for all $x \in A$, can be shown. Under certain conditions, it can also be shown that g is continuous, and differentiable. Such a theorem, known as the *implicit function theorem*, can be proven.

Example 39.6. Let $E = \mathbb{R}^2$, $F = G = \mathbb{R}$, $\Omega = \mathbb{R}^2 \times \mathbb{R} \cong \mathbb{R}^3$, $f: \mathbb{R}^2 \times \mathbb{R} \rightarrow \mathbb{R}$ given by

$$f((x_1, x_2), x_3) = x_1^2 + x_2^2 + x_3^2 - 1,$$

$a = (\sqrt{3}/(2\sqrt{2}), \sqrt{3}/(2\sqrt{2}))$, $b = 1/2$, and $c = 0$. The set of vectors $(x_1, x_2, x_3) \in \mathbb{R}^3$ such that

$$f((x_1, x_2), x_3) = x_1^2 + x_2^2 + x_3^2 - 1 = 0$$

is the unit sphere in \mathbb{R}^3 . The vector (a, b) belongs to the unit sphere since $\|a\|_2^2 + b^2 - 1 = 0$. The function $g: \mathbb{R}^2 \rightarrow \mathbb{R}$ given by

$$g(x_1, x_2) = \sqrt{1 - x_1^2 - x_2^2}$$

satisfies the equation

$$f(x_1, x_2, g(x_1, x_2)) = 0$$

all for (x_1, x_2) in the open disk $\{(x_1, x_2) \in \mathbb{R}^2 \mid x_1^2 + x_2^2 < 1\}$, and $g(a) = b$. Observe that if we had picked $b = -1/2$, then we would need to consider the function

$$g(x_1, x_2) = -\sqrt{1 - x_1^2 - x_2^2}.$$

We now state a very general version of the implicit function theorem. The proof of this theorem is fairly involved and uses a fixed-point theorem for contracting mappings in complete metric spaces; it is given in Schwartz [151]. Other proofs can be found in Lang [111] and Cartan [34].

Theorem 39.14. *Let E, F , and G , be normed affine spaces, let Ω be an open subset of $E \times F$, let $f: \Omega \rightarrow G$ be a function defined on Ω , let $(a, b) \in \Omega$, let $c \in G$, and assume that $f(a, b) = c$. If the following assumptions hold*

(1) *The function $f: \Omega \rightarrow G$ is continuous on Ω ;*

(2) *F is a complete normed affine space (and so is G);*

(3) *$\frac{\partial f}{\partial y}(x, y)$ exists for every $(x, y) \in \Omega$, and $\frac{\partial f}{\partial y}: \Omega \rightarrow \mathcal{L}(\vec{F}; \vec{G})$ is continuous;*

(4) *$\frac{\partial f}{\partial y}(a, b)$ is a bijection of $\mathcal{L}(\vec{F}; \vec{G})$, and $\left(\frac{\partial f}{\partial y}(a, b)\right)^{-1} \in \mathcal{L}(\vec{G}; \vec{F})$;*

then the following properties hold:

(a) *There exist some open subset $A \subseteq E$ containing a and some open subset $B \subseteq F$ containing b , such that $A \times B \subseteq \Omega$, and for every $x \in A$, the equation $f(x, y) = c$ has a single solution $y = g(x)$, and thus, there is a unique function $g: A \rightarrow B$ such that $f(x, g(x)) = c$, for all $x \in A$;*

(b) *The function $g: A \rightarrow B$ is continuous.*

If we also assume that

(5) *The derivative $Df(a, b)$ exists;*

then

(c) *The derivative $Dg(a)$ exists, and*

$$Dg(a) = -\left(\frac{\partial f}{\partial y}(a, b)\right)^{-1} \circ \frac{\partial f}{\partial x}(a, b);$$

and if in addition

(6) $\frac{\partial f}{\partial x}: \Omega \rightarrow \mathcal{L}(\vec{E}; \vec{G})$ *is also continuous (and thus, in view of (3), f is C^1 on Ω);*

then

(d) *The derivative $Dg: A \rightarrow \mathcal{L}(\vec{E}; \vec{F})$ is continuous, and*

$$Dg(x) = -\left(\frac{\partial f}{\partial y}(x, g(x))\right)^{-1} \circ \frac{\partial f}{\partial x}(x, g(x)),$$

for all $x \in A$.

Example 39.7. Going back to Example 39.6, write $x = (x_1, x_2)$ and $y = x_3$, so that the partial derivatives $\partial f/\partial x$ and $\partial f/\partial y$ are given in terms of their Jacobian matrices by

$$\begin{aligned}\frac{\partial f}{\partial x}(x, y) &= (2x_1 \quad 2x_2) \\ \frac{\partial f}{\partial y}(x, y) &= 2x_3.\end{aligned}$$

If $0 < |b| \leq 1$ and $\|a\|_2^2 + b^2 - 1 = 0$, then Conditions (3) and (4) are satisfied. Conditions (1) and (2) obviously hold. Since $Df_{(a,b)}$ is given by its Jacobian matrix as

$$Df_{(a,b)} = (2a_1 \quad 2a_2 \quad 2b),$$

Condition (5) holds, and clearly, Condition (6) also holds.

Theorem 39.14 implies that there is some open subset A of \mathbb{R}^2 containing a , some open subset B of \mathbb{R} containing b , and a unique function $g: A \rightarrow B$ such that

$$f(x, g(x)) = 0$$

for all $x \in A$. In fact, we can pick A to be the open unit disk in \mathbb{R}^2 , $B = (0, 2)$, and if $0 < b \leq 1$, then

$$g(x_1, x_2) = \sqrt{1 - x_1^2 - x_2^2},$$

else if $-1 \leq b < 0$, then

$$g(x_1, x_2) = -\sqrt{1 - x_1^2 - x_2^2}.$$

Assuming $0 < b \leq 1$, We have

$$\frac{\partial f}{\partial x}(x, g(x)) = (2x_1 \ 2x_2),$$

and

$$\left(\frac{\partial f}{\partial y}(x, g(x)) \right)^{-1} = \frac{1}{2\sqrt{1 - x_1^2 - x_2^2}},$$

so according to the theorem,

$$dg_x = -\frac{1}{\sqrt{1 - x_1^2 - x_2^2}}(x_1 \ x_2),$$

which matches the derivative of g computed directly.

Observe that the functions $(x_1, x_2) \mapsto \sqrt{1 - x_1^2 - x_2^2}$ and $(x_1, x_2) \mapsto -\sqrt{1 - x_1^2 - x_2^2}$ are two differentiable parametrizations of the sphere, but the union of their ranges does not cover the entire sphere. Since $b \neq 0$, none of the points on the unit circle in the (x_1, x_2) -plane are covered. Our function f views b as lying on the x_3 -axis. In order to cover the entire sphere using this method, we need four more maps, which correspond to b lying on the x_1 -axis or on the x_2 axis. Then we get the additional (implicit) maps $(x_2, x_3) \mapsto \pm\sqrt{1 - x_2^2 - x_3^2}$ and $(x_1, x_3) \mapsto \pm\sqrt{1 - x_1^2 - x_3^2}$.

The implicit function theorem plays an important role in the calculus of variations.

We now consider another very important notion, that of a (local) diffeomorphism.

Definition 39.8. Given two topological spaces E and F , and an open subset A of E , we say that a function $f: A \rightarrow F$ is a *local homeomorphism from A to F* if for every $a \in A$, there is an open set $U \subseteq A$ containing a and an open set V containing $f(a)$ such that f is a homeomorphism from U to $V = f(U)$. If B is an open subset of F , we say that $f: A \rightarrow F$ is a *(global) homeomorphism from A to B* if f is a homeomorphism from A to $B = f(A)$. If E and F are normed affine spaces, we say that $f: A \rightarrow F$ is a *local diffeomorphism from A to F* if for every $a \in A$, there is an open set $U \subseteq A$ containing a and an open set V containing $f(a)$ such that f is a bijection from U to V , f is a C^1 -function on U , and f^{-1} is a C^1 -function on $V = f(U)$. We say that $f: A \rightarrow F$ is a *(global) diffeomorphism from A to B* if f is a homeomorphism from A to $B = f(A)$, f is a C^1 -function on A , and f^{-1} is a C^1 -function on B .

Note that a local diffeomorphism is a local homeomorphism. Also, as a consequence of Proposition 39.8, if f is a diffeomorphism on A , then $Df(a)$ is a linear isomorphism for every $a \in A$. The following theorem can be shown. In fact, there is a fairly simple proof using Theorem 39.14.

Theorem 39.15. (*Inverse Function Theorem*) Let E and F be complete normed affine spaces, let A be an open subset of E , and let $f: A \rightarrow F$ be a C^1 -function on A . The following properties hold:

- (1) For every $a \in A$, if $Df(a)$ is a linear isomorphism (which means that both $Df(a)$ and $(Df(a))^{-1}$ are linear and continuous),² then there exist some open subset $U \subseteq A$ containing a , and some open subset V of F containing $f(a)$, such that f is a diffeomorphism from U to $V = f(U)$. Furthermore,

$$Df^{-1}(f(a)) = (Df(a))^{-1}.$$

For every neighborhood N of a , its image $f(N)$ is a neighborhood of $f(a)$, and for every open ball $U \subseteq A$ of center a , its image $f(U)$ contains some open ball of center $f(a)$.

- (2) If $Df(a)$ is invertible for every $a \in A$, then $B = f(A)$ is an open subset of F , and f is a local diffeomorphism from A to B . Furthermore, if f is injective, then f is a diffeomorphism from A to B .

Proofs of the inverse function theorem can be found in Schwartz [151], Lang [111], Abraham and Marsden [1], and Cartan [34].

The idea of Schwartz's proof is that if we define the function $f_1: F \times \Omega \rightarrow F$ by

$$f_1(y, z) = f(z) - y,$$

then an inverse $g = f^{-1}$ of f is an implicit solution of the equation $f_1(y, z) = 0$, since $f_1(y, g(y)) = f(g(y)) - y = 0$. Observe that the roles of E and F are switched, but this is not a problem since F is complete. The proof consists in checking that the conditions of Theorem 39.14 apply.

Part (1) of Theorem 39.15 is often referred to as the “(local) inverse function theorem.” It plays an important role in the study of manifolds and (ordinary) differential equations.

If E and F are both of finite dimension, and some frames have been chosen, the invertibility of $Df(a)$ is equivalent to the fact that the Jacobian determinant $\det(J(f)(a))$ is nonnull. The case where $Df(a)$ is just injective or just surjective is also important for defining manifolds, using implicit definitions.

Definition 39.9. Let E and F be normed affine spaces, where E and F are of finite dimension (or both E and F are complete), and let A be an open subset of E . For any $a \in A$, a C^1 -function $f: A \rightarrow F$ is an *immersion at a* if $Df(a)$ is injective. A C^1 -function $f: A \rightarrow F$ is a *submersion at a* if $Df(a)$ is surjective. A C^1 -function $f: A \rightarrow F$ is an *immersion on A* (resp. *a submersion on A*) if $Df(a)$ is injective (resp. surjective) for every $a \in A$.

²Actually, since E and F are Banach spaces, by the Open Mapping Theorem, it is sufficient to assume that $Df(a)$ is continuous and bijective; see Lang [111].

When E and F are finite dimensional with $\dim(E) = n$ and $\dim(F) = m$, if $m \geq n$, then f is an immersion iff the Jacobian matrix, $J(f)(a)$, has full rank n for all $a \in E$ and if $n \geq m$, then f is a submersion iff the Jacobian matrix, $J(f)(a)$, has full rank m for all $a \in E$.

Example 39.8. For example, $f: \mathbb{R} \rightarrow \mathbb{R}^2$ defined by $f(t) = (\cos(t), \sin(t))$ is an immersion since $J(f)(t) = \begin{pmatrix} -\sin(t) \\ \cos(t) \end{pmatrix}$ has rank 1 for all t . On the other hand, $f: \mathbb{R} \rightarrow \mathbb{R}^2$ defined by $f(t) = (t^2, t^2)$ is not an immersion since $J(f)(t) = \begin{pmatrix} 2t \\ 2t \end{pmatrix}$ vanishes at $t = 0$. See Figure 39.6. An example of a submersion is given by the projection map $f: \mathbb{R}^2 \rightarrow \mathbb{R}$, where $f(x, y) = x$, since $J(f)(x, y) = (1 \ 0)$.

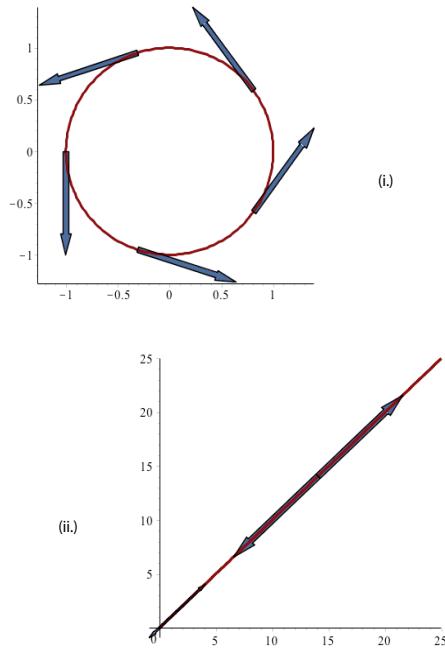

Figure 39.6: Figure (i.) is the immersion of \mathbb{R} into \mathbb{R}^2 given by $f(t) = (\cos(t), \sin(t))$. Figure (ii.), the parametric curve $f(t) = (t^2, t^2)$, is not an immersion since the tangent vanishes at the origin.

The following results can be shown.

Proposition 39.16. *Let A be an open subset of \mathbb{R}^n , and let $f: A \rightarrow \mathbb{R}^m$ be a function. For every $a \in A$, $f: A \rightarrow \mathbb{R}^m$ is a submersion at a iff there exists an open subset U of A containing a , an open subset $W \subseteq \mathbb{R}^{n-m}$, and a diffeomorphism $\varphi: U \rightarrow f(U) \times W$, such that,*

$$f = \pi_1 \circ \varphi,$$

where $\pi_1: f(U) \times W \rightarrow f(U)$ is the first projection. Equivalently,

$$(f \circ \varphi^{-1})(y_1, \dots, y_m, \dots, y_n) = (y_1, \dots, y_m).$$

$$\begin{array}{ccc} U \subseteq A & \xrightarrow{\varphi} & f(U) \times W \\ & \searrow f & \downarrow \pi_1 \\ & & f(U) \subseteq \mathbb{R}^m \end{array}$$

Furthermore, the image of every open subset of A under f is an open subset of F . (The same result holds for \mathbb{C}^n and \mathbb{C}^m). See Figure 39.7.

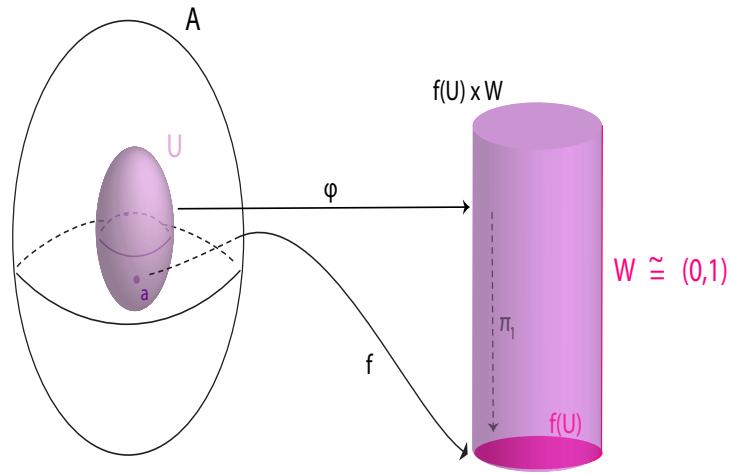

Figure 39.7: Let $n = 3$ and $m = 2$. The submersion maps the solid lavender egg in \mathbb{R}^3 onto the bottom pink circular face of the solid cylinder $f(U) \times W$.

Proposition 39.17. Let A be an open subset of \mathbb{R}^n , and let $f: A \rightarrow \mathbb{R}^m$ be a function. For every $a \in A$, $f: A \rightarrow \mathbb{R}^m$ is an immersion at a iff there exists an open subset U of A containing a , an open subset V containing $f(a)$ such that $f(U) \subseteq V$, an open subset W containing 0 such that $W \subseteq \mathbb{R}^{m-n}$, and a diffeomorphism $\varphi: V \rightarrow U \times W$, such that,

$$\varphi \circ f = in_1,$$

where $in_1: U \rightarrow U \times W$ is the injection map such that $in_1(u) = (u, 0)$, or equivalently,

$$(\varphi \circ f)(x_1, \dots, x_n) = (x_1, \dots, x_n, 0, \dots, 0).$$

$$\begin{array}{ccc} U \subseteq A & \xrightarrow{f} & f(U) \subseteq V \\ & \searrow in_1 & \downarrow \varphi \\ & & U \times W \end{array}$$

(The same result holds for \mathbb{C}^n and \mathbb{C}^m). See Figure 39.8.

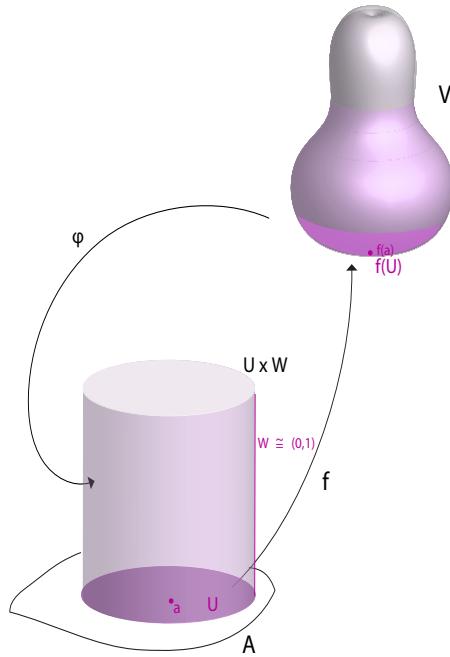

Figure 39.8: Let $n = 2$ and $m = 3$. The immersion maps the purple circular base of the cylinder $U \times W$ to circular cup on the surface of the solid purple gourd.

39.5 Tangent Spaces and Differentials

In this section, we discuss briefly a geometric interpretation of the notion of derivative. We consider sets of points defined by a differentiable function. This is a special case of the notion of a (differential) manifold.

Given two normed affine spaces E and F , let A be an open subset of E , and let $f: A \rightarrow F$ be a function.

Definition 39.10. Given $f: A \rightarrow F$ as above, its *graph* $\Gamma(f)$ is the set of all points

$$\Gamma(f) = \{(x, y) \in E \times F \mid x \in A, y = f(x)\}.$$

If Df is defined on A , we say that $\Gamma(f)$ is a *differential submanifold of $E \times F$ of equation $y = f(x)$* .

It should be noted that this is a very particular kind of differential manifold.

Example 39.9. If $E = \mathbb{R}$ and $F = \mathbb{R}^2$, letting $f = (g, h)$, where $g: \mathbb{R} \rightarrow \mathbb{R}$ and $h: \mathbb{R} \rightarrow \mathbb{R}$, $\Gamma(f)$ is a curve in \mathbb{R}^3 , of equations $y = g(x)$, $z = h(x)$. When $E = \mathbb{R}^2$ and $F = \mathbb{R}$, $\Gamma(f)$ is a surface in \mathbb{R}^3 , of equation $z = f(x, y)$.

We now define the notion of affine tangent space in a very general way. Next, we will see what it means for manifolds $\Gamma(f)$, as in Definition 39.10.

Definition 39.11. Given a normed affine space E , given any nonempty subset M of E , given any point $a \in M$, we say that a vector $u \in \vec{E}$ is *tangent at a to M* if there exist a sequence $(a_n)_{n \in \mathbb{N}}$ of points in M converging to a , and a sequence $(\lambda_n)_{n \in \mathbb{N}}$, with $\lambda_i \in \mathbb{R}$ and $\lambda_n \geq 0$, such that the sequence $(\lambda_n(a_n - a))_{n \in \mathbb{N}}$ converges to u .

The set of all vectors tangent at a to M is called the *family of tangent vectors at a to M* and the set of all points of E of the form $a + u$ where u belongs to the family of tangent vectors at a to M is called the *affine tangent family at a to M* .

Clearly, 0 is always tangent, and if u is tangent, then so is every λu , for $\lambda \in \mathbb{R}$, $\lambda \geq 0$. If $u \neq 0$, then the sequence $(\lambda_n)_{n \in \mathbb{N}}$ must tend towards $+\infty$. We have the following proposition.

Proposition 39.18. *Let E and F be two normed affine spaces, let A be an open subset of E , let $a \in A$, and let $f: A \rightarrow F$ be a function. If $Df(a)$ exists, then the family of tangent vectors at $(a, f(a))$ to Γ is a subspace $T_a(\Gamma)$ of $\vec{E} \times \vec{F}$, defined by the condition (equation)*

$$(u, v) \in T_a(\Gamma) \quad \text{iff} \quad v = Df(a)(u),$$

and the affine tangent family at $(a, f(a))$ to Γ is an affine variety $T_a(\Gamma)$ of $E \times F$, defined by the condition (equation)

$$(x, y) \in T_a(\Gamma) \quad \text{iff} \quad y = f(a) + Df(a)(x - a),$$

where Γ is the graph of f .

The proof is actually rather simple. We have $T_a(\Gamma) = a + T_a(\Gamma)$, and since $T_a(\Gamma)$ is a subspace of $\vec{E} \times \vec{F}$, the set $T_a(\Gamma)$ is an affine variety. Thus, the affine tangent space at a point $(a, f(a))$ is a familiar object, a line, a plane, etc.

As an illustration, when $E = \mathbb{R}^2$ and $F = \mathbb{R}$, the affine tangent plane at the point (a, b, c) to the surface of equation $z = f(x, y)$, is defined by the equation

$$z = c + \frac{\partial f}{\partial x}(a, b)(x - a) + \frac{\partial f}{\partial y}(a, b)(y - b).$$

If $E = \mathbb{R}$ and $F = \mathbb{R}^2$, the tangent line at (a, b, c) , to the curve of equations $y = g(x)$, $z = h(x)$, is defined by the equations

$$\begin{aligned} y &= b + Dg(a)(x - a), \\ z &= c + Dh(a)(x - a). \end{aligned}$$

Thus, derivatives and partial derivatives have the desired intended geometric interpretation as tangent spaces. Of course, in order to deal with this topic properly, we really would have to go deeper into the study of (differential) manifolds.

We now briefly consider second-order and higher-order derivatives.

39.6 Second-Order and Higher-Order Derivatives

Given two normed affine spaces E and F , and some open subset A of E , if $Df(a)$ is defined for every $a \in A$, then we have a mapping $Df: A \rightarrow \mathcal{L}(\vec{E}; \vec{F})$. Since $\mathcal{L}(\vec{E}; \vec{F})$ is a normed vector space, if Df exists on an open subset U of A containing a , we can consider taking the derivative of Df at some $a \in A$.

Definition 39.12. Given a function $f: A \rightarrow F$ defined on some open subset A of E such that $Df(a)$ is defined for every $a \in A$, If $D(Df)(a)$ exists for every $a \in A$, we get a mapping $D^2f: A \rightarrow \mathcal{L}(\vec{E}; \mathcal{L}(\vec{E}; \vec{F}))$ called the *second derivative of f on A* , where $D^2f(a) = D(Df)(a)$, for every $a \in A$.

As in the case of the first derivative Df_a where $Df_a(u) = D_u f(a)$, where $D_u f(a)$ is the directional derivative of f at a in the direction u , it would be useful to express $D^2f(a)(u)(v)$ in terms of two directional derivatives. This can indeed be done. If $D^2f(a)$ exists, then for every $u \in \vec{E}$,

$$D^2f(a)(u) = D(Df)(a)(u) = D_u(Df)(a) \in \mathcal{L}(\vec{E}; \vec{F}).$$

We have the following result.

Proposition 39.19. *If $D^2f(a)$ exists, then $D_u(D_v f)(a)$ exists and*

$$D^2f(a)(u)(v) = D_u(D_v f)(a), \quad \text{for all } u, v \in \vec{E}.$$

Proof. Recall from Proposition 37.61, that the map app from $\mathcal{L}(\vec{E}; \vec{F}) \times \vec{E}$ to \vec{F} , defined such that for every $L \in \mathcal{L}(\vec{E}; \vec{F})$, for every $v \in \vec{E}$,

$$\text{app}(L, v) = L(v),$$

is a continuous bilinear map. Thus, in particular, given a fixed $v \in \vec{E}$, the linear map $\text{app}_v: \mathcal{L}(\vec{E}; \vec{F}) \rightarrow \vec{F}$, defined such that $\text{app}_v(L) = L(v)$, is a continuous map.

Also recall from Proposition 39.7, that if $h: A \rightarrow G$ is a function such that $Dh(a)$ exists, and $k: G \rightarrow H$ is a continuous linear map, then, $D(k \circ h)(a)$ exists, and

$$k(Dh(a)(u)) = D(k \circ h)(a)(u),$$

that is,

$$k(D_u h(a)) = D_u(k \circ h)(a),$$

Applying these two facts to $h = Df$, and to $k = \text{app}_v$, we have

$$D_u(Df)(a)(v) = D_u(\text{app}_v \circ Df)(a).$$

But $(\text{app}_v \circ Df)(x) = Df(x)(v) = D_v f(x)$, for every $x \in A$, that is, $\text{app}_v \circ Df = D_v f$ on A . So, we have

$$D_u(Df)(a)(v) = D_u(D_v f)(a),$$

and since $D^2f(a)(u) = D_u(Df)(a)$, we get

$$D^2f(a)(u)(v) = D_u(D_v f)(a).$$

Thus, when $D^2f(a)$ exists, $D_u(D_v f)(a)$ exists, and

$$D^2f(a)(u)(v) = D_u(D_v f)(a),$$

for all $u, v \in \vec{E}$. □

Definition 39.13. We denote $D_u(D_v f)(a)$ by $D_{u,v}^2 f(a)$ (or $D_u D_v f(a)$).

Recall from Proposition 37.60, that the map from $\mathcal{L}_2(\vec{E}, \vec{E}; \vec{F})$ to $\mathcal{L}(\vec{E}; \mathcal{L}(\vec{E}; \vec{F}))$ defined such that $g \mapsto \varphi$ iff for every $g \in \mathcal{L}_2(\vec{E}, \vec{E}; \vec{F})$,

$$\varphi(u)(v) = g(u, v),$$

is an isomorphism of vector spaces. Thus, we will consider $D^2f(a) \in \mathcal{L}(\vec{E}; \mathcal{L}(\vec{E}; \vec{F}))$ as a continuous bilinear map in $\mathcal{L}_2(\vec{E}, \vec{E}; \vec{F})$, and we will write $D^2f(a)(u, v)$, instead of $D^2f(a)(u)(v)$.

Then, the above discussion can be summarized by saying that when $D^2f(a)$ is defined, we have

$$D^2f(a)(u, v) = D_u D_v f(a).$$

Definition 39.14. When E has finite dimension and $(a_0, (e_1, \dots, e_n))$ is a frame for E , we denote $D_{e_j} D_{e_i} f(a)$ by $\frac{\partial^2 f}{\partial x_i \partial x_j}(a)$, when $i \neq j$, and we denote $D_{e_i} D_{e_i} f(a)$ by $\frac{\partial^2 f}{\partial x_i^2}(a)$.

The following important lemma attributed to Schwarz can be shown, using Proposition 39.12. Given a bilinear map $f: \vec{E} \times \vec{E} \rightarrow \vec{F}$, recall that f is *symmetric*, if

$$f(u, v) = f(v, u),$$

for all $u, v \in \vec{E}$.

Proposition 39.20. (Schwarz's lemma) Given two normed affine spaces E and F , given any open subset A of E , given any $f: A \rightarrow F$, for every $a \in A$, if $D^2f(a)$ exists, then $D^2f(a) \in \mathcal{L}_2(\vec{E}, \vec{E}; \vec{F})$ is a continuous symmetric bilinear map. As a corollary, if E is of finite dimension n , and $(a_0, (e_1, \dots, e_n))$ is a frame for E , we have

$$\frac{\partial^2 f}{\partial x_i \partial x_j}(a) = \frac{\partial^2 f}{\partial x_j \partial x_i}(a).$$

Remark: There is a variation of the above result which does not assume the existence of $D^2f(a)$, but instead assumes that $D_u D_v f$ and $D_v D_u f$ exist on an open subset containing a and are continuous at a , and concludes that $D_u D_v f(a) = D_v D_u f(a)$. This is just a different result which does not imply Proposition 39.20, and is not a consequence of Proposition 39.20.

When $E = \mathbb{R}^2$, the only existence of $\frac{\partial^2 f}{\partial x \partial y}(a)$ and $\frac{\partial^2 f}{\partial y \partial x}(a)$ is not sufficient to insure the existence of $D^2 f(a)$.

When E if of finite dimension n and $(a_0, (e_1, \dots, e_n))$ is a frame for E , if $D^2 f(a)$ exists, for every $u = u_1 e_1 + \dots + u_n e_n$ and $v = v_1 e_1 + \dots + v_n e_n$ in \vec{E} , since $D^2 f(a)$ is a symmetric bilinear form, we have

$$D^2 f(a)(u, v) = \sum_{i=1, j=1}^n u_i v_j \frac{\partial^2 f}{\partial x_i \partial x_j}(a),$$

which can be written in matrix form as:

$$D^2 f(a)(u, v) = U^\top \begin{pmatrix} \frac{\partial^2 f}{\partial x_1^2}(a) & \frac{\partial^2 f}{\partial x_1 \partial x_2}(a) & \dots & \frac{\partial^2 f}{\partial x_1 \partial x_n}(a) \\ \frac{\partial^2 f}{\partial x_1 \partial x_2}(a) & \frac{\partial^2 f}{\partial x_2^2}(a) & \dots & \frac{\partial^2 f}{\partial x_2 \partial x_n}(a) \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial^2 f}{\partial x_1 \partial x_n}(a) & \frac{\partial^2 f}{\partial x_2 \partial x_n}(a) & \dots & \frac{\partial^2 f}{\partial x_n^2}(a) \end{pmatrix} V$$

where U is the column matrix representing u , and V is the column matrix representing v , over the frame $(a_0, (e_1, \dots, e_n))$.

Definition 39.15. The above symmetric matrix is called the *Hessian of f at a* .

Example 39.10. Consider the function f defined on real invertible 2×2 matrices such that $ad - bc > 0$ given by

$$f(a, b, c, d) = \log(ad - bc).$$

We immediately verify that the Jacobian matrix of f is given by

$$df_{a,b,c,d} = \frac{1}{ad - bc} \begin{pmatrix} d & -c & -b & a \end{pmatrix}.$$

It is easily checked that if

$$A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}, \quad X = \begin{pmatrix} x_1 & x_2 \\ x_3 & x_4 \end{pmatrix},$$

then

$$df_A(X) = \text{tr}(A^{-1}X) = \frac{1}{ad - bc} \text{tr} \left(\begin{pmatrix} d & -b \\ -c & a \end{pmatrix} \begin{pmatrix} x_1 & x_2 \\ x_3 & x_4 \end{pmatrix} \right).$$

Computing second-order derivatives, we find that the Hessian matrix of f is given by

$$Hf(A) = \frac{1}{(ad - bc)^2} \begin{pmatrix} -d^2 & cd & bd & -bc \\ cd & -c^2 & -ad & ac \\ bd & -ad & -b^2 & ab \\ -bc & ac & ab & -a^2 \end{pmatrix}.$$

Using the formula for the derivative of the inversion map and the chain rule we can show that

$$D^2 f(A)(X_1, X_2) = -\text{tr}(A^{-1} X_1 A^{-1} X_2),$$

and so

$$Hf(A)(X_1, X_2) = -\text{tr}(A^{-1} X_1 A^{-1} X_2),$$

a formula which is far from obvious.

The function f can be generalized to matrices $A \in \mathbf{GL}^+(n, \mathbb{R})$, that is, $n \times n$ real invertible matrices of positive determinants, as

$$f(A) = \log \det(A).$$

It can be shown that the formulae

$$\begin{aligned} df_A(X) &= \text{tr}(A^{-1} X) \\ D^2 f(A)(X_1, X_2) &= -\text{tr}(A^{-1} X_1 A^{-1} X_2) \end{aligned}$$

also hold.

Example 39.11. If we restrict the function of Example 39.10 to symmetric positive definite matrices we obtain the function g defined by

$$g(a, b, c) = \log(ac - b^2).$$

We immediately verify that the Jacobian matrix of g is given by

$$dg_{a,b,c} = \frac{1}{ac - b^2} \begin{pmatrix} c & -2b & a \end{pmatrix}.$$

Computing second-order derivatives, we find that the Hessian matrix of g is given by

$$Hg(a, b, c) = \frac{1}{(ac - b^2)^2} \begin{pmatrix} -c^2 & 2bc & -b^2 \\ 2bc & -2(b^2 + ac) & 2ab \\ -b^2 & 2ab & -a^2 \end{pmatrix}.$$

Although this is not obvious, it can be shown that if $ac - b^2 > 0$ and $a, c > 0$, then the matrix $-Hg(a, b, c)$ is symmetric positive definite.

If F itself is of finite dimension, and $(b_0, (v_1, \dots, v_m))$ is a frame for F , then $f = (f_1, \dots, f_m)$, and each component $D^2 f(a)_i(u, v)$ of $D^2 f(a)(u, v)$ ($1 \leq i \leq m$), can be written as

$$D^2 f(a)_i(u, v) = U^\top \begin{pmatrix} \frac{\partial^2 f_i}{\partial x_1^2}(a) & \frac{\partial^2 f_i}{\partial x_1 \partial x_2}(a) & \dots & \frac{\partial^2 f_i}{\partial x_1 \partial x_n}(a) \\ \frac{\partial^2 f_i}{\partial x_1 \partial x_2}(a) & \frac{\partial^2 f_i}{\partial x_2^2}(a) & \dots & \frac{\partial^2 f_i}{\partial x_2 \partial x_n}(a) \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial^2 f_i}{\partial x_1 \partial x_n}(a) & \frac{\partial^2 f_i}{\partial x_2 \partial x_n}(a) & \dots & \frac{\partial^2 f_i}{\partial x_n^2}(a) \end{pmatrix} V$$

Thus, we could describe the vector $D^2 f(a)(u, v)$ in terms of an $mn \times mn$ -matrix consisting of m diagonal blocks, which are the above Hessians, and the row matrix (U^\top, \dots, U^\top) (m times) and the column matrix consisting of m copies of V .

We now indicate briefly how higher-order derivatives are defined. Let $m \geq 2$. Given a function $f: A \rightarrow F$ as before, for any $a \in A$, if the derivatives $D^i f$ exist on A for all i , $1 \leq i \leq m-1$, by induction, $D^{m-1} f$ can be considered to be a continuous function $D^{m-1} f: A \rightarrow \mathcal{L}_{m-1}(\overrightarrow{E^{m-1}}; \overrightarrow{F})$.

Definition 39.16. Define $D^m f(a)$, the m -th derivative of f at a , as

$$D^m f(a) = D(D^{m-1} f)(a).$$

Then $D^m f(a)$ can be identified with a continuous m -multilinear map in $\mathcal{L}_m(\overrightarrow{E^m}; \overrightarrow{F})$. We can then show (as we did before), that if $D^m f(a)$ is defined, then

$$D^m f(a)(u_1, \dots, u_m) = D_{u_1} \dots D_{u_m} f(a).$$

Definition 39.17. When E is of finite dimension n and $(a_0, (e_1, \dots, e_n))$ is a frame for E , if $D^m f(a)$ exists, for every $j_1, \dots, j_m \in \{1, \dots, n\}$, we denote $D_{e_{j_m}} \dots D_{e_{j_1}} f(a)$ by

$$\frac{\partial^m f}{\partial x_{j_1} \dots \partial x_{j_m}}(a).$$

Example 39.12. Going back to the function f of Example 39.10 given by $f(A) = \log \det(A)$, using the formula for the derivative of the inversion map, the chain rule and the product rule, we can show that

$$D^m f(A)(X_1, \dots, X_m) = (-1)^{m-1} \sum_{\sigma \in \mathfrak{S}_{m-1}} \text{tr}(A^{-1} X_1 A^{-1} X_{\sigma(1)+1} A^{-1} X_{\sigma(2)+1} \dots A^{-1} X_{\sigma(m-1)+1})$$

for any $m \geq 1$, where $A \in \mathbf{GL}^+(n, \mathbb{R})$ and X_1, \dots, X_m are any $n \times n$ real matrices.

Given a m -multilinear map $f \in \mathcal{L}_m(\overrightarrow{E^m}; \overrightarrow{F})$, recall that f is *symmetric* if

$$f(u_{\pi(1)}, \dots, u_{\pi(m)}) = f(u_1, \dots, u_m),$$

for all $u_1, \dots, u_m \in \overrightarrow{E}$, and all permutations π on $\{1, \dots, m\}$. Then, the following generalization of Schwarz's lemma holds.

Proposition 39.21. *Given two normed affine spaces E and F , given any open subset A of E , given any $f: A \rightarrow F$, for every $a \in A$, for every $m \geq 1$, if $D^m f(a)$ exists, then $D^m f(a) \in \mathcal{L}_m(\overrightarrow{E^m}; \overrightarrow{F})$ is a continuous symmetric m -multilinear map. As a corollary, if E is of finite dimension n , and $(a_0, (e_1, \dots, e_n))$ is a frame for E , we have*

$$\frac{\partial^m f}{\partial x_{j_1} \dots \partial x_{j_m}}(a) = \frac{\partial^m f}{\partial x_{\pi(j_1)} \dots \partial x_{\pi(j_m)}}(a),$$

for every $j_1, \dots, j_m \in \{1, \dots, n\}$, and for every permutation π on $\{1, \dots, m\}$.

Because the trace function is invariant under permutation of its arguments ($\text{tr}(XY) = \text{tr}(YX)$), we see that the m -th derivatives in Example 39.12 are indeed symmetric multilinear maps.

If E is of finite dimension n , and $(a_0, (e_1, \dots, e_n))$ is a frame for E , $D^m f(a)$ is a symmetric m -multilinear map, and we have

$$D^m f(a)(u_1, \dots, u_m) = \sum_j u_{1,j_1} \cdots u_{m,j_m} \frac{\partial^m f}{\partial x_{j_1} \cdots \partial x_{j_m}}(a),$$

where j ranges over all functions $j: \{1, \dots, m\} \rightarrow \{1, \dots, n\}$, for any m vectors

$$u_j = u_{j,1}e_1 + \cdots + u_{j,n}e_n.$$

The concept of C^1 -function is generalized to the concept of C^m -function, and Theorem 39.13 can also be generalized.

Definition 39.18. Given two normed affine spaces E and F , and an open subset A of E , for any $m \geq 1$, we say that a function $f: A \rightarrow F$ is *of class C^m on A or a C^m -function on A* if $D^k f$ exists and is continuous on A for every k , $1 \leq k \leq m$. We say that $f: A \rightarrow F$ is *of class C^∞ on A or a C^∞ -function on A* if $D^k f$ exists and is continuous on A for every $k \geq 1$. A C^∞ -function (on A) is also called a *smooth function* (on A). A C^m -diffeomorphism $f: A \rightarrow B$ between A and B (where A is an open subset of E and B is an open subset of F) is a bijection between A and $B = f(A)$, such that both $f: A \rightarrow B$ and its inverse $f^{-1}: B \rightarrow A$ are C^m -functions.

Equivalently, f is a C^m -function on A if f is a C^1 -function on A and Df is a C^{m-1} -function on A .

We have the following theorem giving a necessary and sufficient condition for f to a C^m -function on A . A generalization to the case where $E = (E_1, a_1) \oplus \cdots \oplus (E_n, a_n)$ also holds.

Theorem 39.22. *Given two normed affine spaces E and F , where E is of finite dimension n , and where $(a_0, (u_1, \dots, u_n))$ is a frame of E , given any open subset A of E , given any function $f: A \rightarrow F$, for any $m \geq 1$, the derivative $D^m f$ is a C^m -function on A iff every partial derivative $D_{u_{j_k}} \cdots D_{u_{j_1}} f$ (or $\frac{\partial^k f}{\partial x_{j_1} \cdots \partial x_{j_k}}(a)$) is defined and continuous on A , for all k , $1 \leq k \leq m$, and all $j_1, \dots, j_k \in \{1, \dots, n\}$. As a corollary, if F is of finite dimension p , and $(b_0, (v_1, \dots, v_p))$ is a frame of F , the derivative $D^m f$ is defined and continuous on A iff every partial derivative $D_{u_{j_k}} \cdots D_{u_{j_1}} f_i$ (or $\frac{\partial^k f_i}{\partial x_{j_1} \cdots \partial x_{j_k}}(a)$) is defined and continuous on A , for all k , $1 \leq k \leq m$, for all i , $1 \leq i \leq p$, and all $j_1, \dots, j_k \in \{1, \dots, n\}$.*

Definition 39.19. When $E = \mathbb{R}$ (or $E = \mathbb{C}$), for any $a \in E$, $D^m f(a)(1, \dots, 1)$ is a vector in \vec{F} , called the *m th-order vector derivative*. As in the case $m = 1$, we will usually identify the multilinear map $D^m f(a)$ with the vector $D^m f(a)(1, \dots, 1)$.

Some notational conventions can also be introduced to simplify the notation of higher-order derivatives, and we discuss such conventions very briefly.

Recall that when E is of finite dimension n , and $(a_0, (e_1, \dots, e_n))$ is a frame for E , $D^m f(a)$ is a symmetric m -multilinear map, and we have

$$D^m f(a)(u_1, \dots, u_m) = \sum_j u_{1,j_1} \cdots u_{m,j_m} \frac{\partial^m f}{\partial x_{j_1} \cdots \partial x_{j_m}}(a),$$

where j ranges over all functions $j: \{1, \dots, m\} \rightarrow \{1, \dots, n\}$, for any m vectors

$$u_j = u_{j,1}e_1 + \cdots + u_{j,n}e_n.$$

We can then group the various occurrences of ∂x_{j_k} corresponding to the same variable x_{j_k} , and this leads to the notation

$$\left(\frac{\partial}{\partial x_1}\right)^{\alpha_1} \left(\frac{\partial}{\partial x_2}\right)^{\alpha_2} \cdots \left(\frac{\partial}{\partial x_n}\right)^{\alpha_n} f(a),$$

where $\alpha_1 + \alpha_2 + \cdots + \alpha_n = m$.

If we denote $(\alpha_1, \dots, \alpha_n)$ simply by α , then we denote

$$\left(\frac{\partial}{\partial x_1}\right)^{\alpha_1} \left(\frac{\partial}{\partial x_2}\right)^{\alpha_2} \cdots \left(\frac{\partial}{\partial x_n}\right)^{\alpha_n} f$$

by

$$\partial^\alpha f, \quad \text{or} \quad \left(\frac{\partial}{\partial x}\right)^\alpha f.$$

If $\alpha = (\alpha_1, \dots, \alpha_n)$, we let $|\alpha| = \alpha_1 + \alpha_2 + \cdots + \alpha_n$, $\alpha! = \alpha_1! \cdots \alpha_n!$, and if $h = (h_1, \dots, h_n)$, we denote $h_1^{\alpha_1} \cdots h_n^{\alpha_n}$ by h^α .

In the next section, we survey various versions of Taylor's formula.

39.7 Taylor's formula, Faà di Bruno's formula

We discuss, without proofs, several versions of Taylor's formula. The hypotheses required in each version become increasingly stronger. The first version can be viewed as a generalization of the notion of derivative. Given an m -linear map $f: \overrightarrow{E^m} \rightarrow \overrightarrow{F}$, for any vector $h \in \overrightarrow{E}$, we abbreviate

$$f(\underbrace{h, \dots, h}_m)$$

by $f(h^m)$. The version of Taylor's formula given next is sometimes referred to as the *formula of Taylor–Young*.

Theorem 39.23. (*Taylor–Young*) Given two normed affine spaces E and F , for any open subset $A \subseteq E$, for any function $f: A \rightarrow F$, for any $a \in A$, if $D^k f$ exists in A for all k , $1 \leq k \leq m - 1$, and if $D^m f(a)$ exists, then we have:

$$f(a + h) = f(a) + \frac{1}{1!} D^1 f(a)(h) + \cdots + \frac{1}{m!} D^m f(a)(h^m) + \|h\|^m \epsilon(h),$$

for any h such that $a + h \in A$, and where $\lim_{h \rightarrow 0, h \neq 0} \epsilon(h) = 0$.

The above version of Taylor's formula has applications to the study of relative maxima (or minima) of real-valued functions. It is also used to study the local properties of curves and surfaces.

The next version of Taylor's formula can be viewed as a generalization of Proposition 39.12. It is sometimes called the *Taylor formula with Lagrange remainder* or *generalized mean value theorem*.

Theorem 39.24. (*Generalized mean value theorem*) Let E and F be two normed affine spaces, let A be an open subset of E , and let $f: A \rightarrow F$ be a function on A . Given any $a \in A$ and any $h \neq 0$ in \overrightarrow{E} , if the closed segment $[a, a + h]$ is contained in A , $D^k f$ exists in A for all k , $1 \leq k \leq m$, $D^{m+1} f(x)$ exists at every point x of the open segment $]a, a + h[$, and

$$\max_{x \in (a, a+h)} \|D^{m+1} f(x)\| \leq M,$$

for some $M \geq 0$, then

$$\left\| f(a + h) - f(a) - \left(\frac{1}{1!} D^1 f(a)(h) + \cdots + \frac{1}{m!} D^m f(a)(h^m) \right) \right\| \leq M \frac{\|h\|^{m+1}}{(m+1)!}.$$

As a corollary, if $L: \overrightarrow{E^{m+1}} \rightarrow \overrightarrow{F}$ is a continuous $(m+1)$ -linear map, then

$$\left\| f(a + h) - f(a) - \left(\frac{1}{1!} D^1 f(a)(h) + \cdots + \frac{1}{m!} D^m f(a)(h^m) + \frac{L(h^{m+1})}{(m+1)!} \right) \right\| \leq M \frac{\|h\|^{m+1}}{(m+1)!},$$

where $M = \max_{x \in (a, a+h)} \|D^{m+1} f(x) - L\|$.

The above theorem is sometimes stated under the slightly stronger assumption that f is a C^m -function on A . If $f: A \rightarrow \mathbb{R}$ is a real-valued function, Theorem 39.24 can be refined a little bit. This version is often called the *formula of Taylor–MacLaurin*.

Theorem 39.25. (*Taylor–MacLaurin*) Let E be a normed affine space, let A be an open subset of \overrightarrow{E} , and let $f: A \rightarrow \mathbb{R}$ be a real-valued function on A . Given any $a \in A$ and any $h \neq 0$ in \overrightarrow{E} , if the closed segment $[a, a + h]$ is contained in A , if $D^k f$ exists in A for all k , $1 \leq k \leq m$, and $D^{m+1} f(x)$ exists at every point x of the open segment $]a, a + h[$, then there is some $\theta \in \mathbb{R}$, with $0 < \theta < 1$, such that

$$f(a + h) = f(a) + \frac{1}{1!} D^1 f(a)(h) + \cdots + \frac{1}{m!} D^m f(a)(h^m) + \frac{1}{(m+1)!} D^{m+1} f(a + \theta h)(h^{m+1}).$$

Example 39.13. Going back to the function f of Example 39.10 given by $f(A) = \log \det(A)$, we know from Example 39.12 that

$$\mathrm{D}^m f(A)(X_1, \dots, X_m) = (-1)^{m-1} \sum_{\sigma \in \mathfrak{S}_{m-1}} \mathrm{tr}(A^{-1} X_1 A^{-1} X_{\sigma(1)+1} \cdots A^{-1} X_{\sigma(m-1)+1}) \quad (*)$$

for all $m \geq 1$, with $A \in \mathbf{GL}^+(n, \mathbb{R})$. If we make the stronger assumption that A is symmetric positive definite, then for any other symmetric positive definite matrix B , since the symmetric positive definite matrices form a convex set, the matrices $A + \theta(B - A) = (1 - \theta)A + \theta B$ are also symmetric positive definite for $\theta \in [0, 1]$. Theorem 39.25 applies with $H = B - A$ (a symmetric matrix), and using $(*)$, we obtain

$$\begin{aligned} \log \det(A + H) &= \log \det(A) + \mathrm{tr} \left(A^{-1} H - \frac{1}{2}(A^{-1} H)^2 + \cdots + \frac{(-1)^{m-1}}{m}(A^{-1} H)^m \right. \\ &\quad \left. + \frac{(-1)^m}{m+1}((A + \theta H)^{-1} H)^{m+1} \right), \end{aligned}$$

for some θ such that $0 < \theta < 1$. In particular, if $A = I$, for any symmetric matrix H such that $I + H$ is symmetric positive definite, we obtain

$$\begin{aligned} \log \det(I + H) &= \mathrm{tr} \left(H - \frac{1}{2}H^2 + \cdots + \frac{(-1)^{m-1}}{m}H^m \right. \\ &\quad \left. + \frac{(-1)^m}{m+1}((I + \theta H)^{-1} H)^{m+1} \right), \end{aligned}$$

for some θ such that $0 < \theta < 1$. In the special case when $n = 1$, we have $I = 1$, H is a real such that $1 + H > 0$ and the trace function is the identity, so we recognize the partial sum of the series for $x \mapsto \log(1 + x)$,

$$\begin{aligned} \log(1 + H) &= H - \frac{1}{2}H^2 + \cdots + \frac{(-1)^{m-1}}{m}H^m \\ &\quad + \frac{(-1)^m}{m+1}(1 + \theta H)^{-(m+1)}H^{m+1}. \end{aligned}$$

We also mention for “mathematical culture,” a version with integral remainder, in the case of a real-valued function. This is usually called *Taylor’s formula with integral remainder*.

Theorem 39.26. (*Taylor’s formula with integral remainder*) Let E be a normed affine space, let A be an open subset of E , and let $f: A \rightarrow \mathbb{R}$ be a real-valued function on A . Given any $a \in A$ and any $h \neq 0$ in \overrightarrow{E} , if the closed segment $[a, a + h]$ is contained in A , and if f is a C^{m+1} -function on A , then we have

$$\begin{aligned} f(a + h) &= f(a) + \frac{1}{1!}\mathrm{D}^1 f(a)(h) + \cdots + \frac{1}{m!}\mathrm{D}^m f(a)(h^m) \\ &\quad + \int_0^1 \frac{(1-t)^m}{m!} [\mathrm{D}^{m+1} f(a + th)(h^{m+1})] dt. \end{aligned}$$

The advantage of the above formula is that it gives an explicit remainder. We now examine briefly the situation where E is of finite dimension n , and $(a_0, (e_1, \dots, e_n))$ is a frame for E . In this case, we get a more explicit expression for the expression

$$\sum_{i=0}^{k=m} \frac{1}{k!} D^k f(a)(h^k)$$

involved in all versions of Taylor's formula, where by convention, $D^0 f(a)(h^0) = f(a)$. If $h = h_1 e_1 + \dots + h_n e_n$, then we have

$$\sum_{k=0}^{k=m} \frac{1}{k!} D^k f(a)(h^k) = \sum_{k_1+\dots+k_n \leq m} \frac{h_1^{k_1} \dots h_n^{k_n}}{k_1! \dots k_n!} \left(\frac{\partial}{\partial x_1} \right)^{k_1} \dots \left(\frac{\partial}{\partial x_n} \right)^{k_n} f(a),$$

which, using the abbreviated notation introduced at the end of Section 39.6, can also be written as

$$\sum_{k=0}^{k=m} \frac{1}{k!} D^k f(a)(h^k) = \sum_{|\alpha| \leq m} \frac{h^\alpha}{\alpha!} \partial^\alpha f(a).$$

The advantage of the above notation is that it is the same as the notation used when $n = 1$, i.e., when $E = \mathbb{R}$ (or $E = \mathbb{C}$). Indeed, in this case, the Taylor–MacLaurin formula reads as:

$$f(a+h) = f(a) + \frac{h}{1!} D^1 f(a) + \dots + \frac{h^m}{m!} D^m f(a) + \frac{h^{m+1}}{(m+1)!} D^{m+1} f(a + \theta h),$$

for some $\theta \in \mathbb{R}$, with $0 < \theta < 1$, where $D^k f(a)$ is the value of the k -th derivative of f at a (and thus, as we have already said several times, this is the k th-order vector derivative, which is just a scalar, since $F = \mathbb{R}$).

In the above formula, the assumptions are that $f: [a, a+h] \rightarrow \mathbb{R}$ is a C^m -function on $[a, a+h]$, and that $D^{m+1} f(x)$ exists for every $x \in (a, a+h)$.

Taylor's formula is useful to study the local properties of curves and surfaces. In the case of a curve, we consider a function $f: [r, s] \rightarrow F$ from a closed interval $[r, s]$ of \mathbb{R} to some affine space F , the derivatives $D^k f(a)(h^k)$ correspond to vectors $h^k D^k f(a)$, where $D^k f(a)$ is the k th vector derivative of f at a (which is really $D^k f(a)(1, \dots, 1)$), and for any $a \in (r, s)$, Theorem 39.23 yields the following formula:

$$f(a+h) = f(a) + \frac{h}{1!} D^1 f(a) + \dots + \frac{h^m}{m!} D^m f(a) + h^m \epsilon(h),$$

for any h such that $a+h \in (r, s)$, and where $\lim_{h \rightarrow 0, h \neq 0} \epsilon(h) = 0$.

In the case of functions $f: \mathbb{R}^n \rightarrow \mathbb{R}$, it is convenient to have formulae for the Taylor–Young formula and the Taylor–MacLaurin formula in terms of the gradient and the Hessian.

Recall that the *gradient* $\nabla f(a)$ of f at $a \in \mathbb{R}^n$ is the column vector

$$\nabla f(a) = \begin{pmatrix} \frac{\partial f}{\partial x_1}(a) \\ \frac{\partial f}{\partial x_2}(a) \\ \vdots \\ \frac{\partial f}{\partial x_n}(a) \end{pmatrix},$$

and that

$$f'(a)(u) = Df(a)(u) = \nabla f(a) \cdot u,$$

for any $u \in \mathbb{R}^n$ (where \cdot means inner product). The above equation shows that *the direction of the gradient $\nabla f(a)$ is the direction of maximal increase of the function f at a* and that $\|\nabla f(a)\|$ is the rate of change of f in its direction of maximal increase. This is the reason why methods of “gradient descent” pick the direction *opposite* to the gradient (we are trying to minimize f).

The *Hessian matrix* $\nabla^2 f(a)$ of f at $a \in \mathbb{R}^n$ is the $n \times n$ symmetric matrix

$$\nabla^2 f(a) = \begin{pmatrix} \frac{\partial^2 f}{\partial x_1^2}(a) & \frac{\partial^2 f}{\partial x_1 \partial x_2}(a) & \dots & \frac{\partial^2 f}{\partial x_1 \partial x_n}(a) \\ \frac{\partial^2 f}{\partial x_1 \partial x_2}(a) & \frac{\partial^2 f}{\partial x_2^2}(a) & \dots & \frac{\partial^2 f}{\partial x_2 \partial x_n}(a) \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial^2 f}{\partial x_1 \partial x_n}(a) & \frac{\partial^2 f}{\partial x_2 \partial x_n}(a) & \dots & \frac{\partial^2 f}{\partial x_n^2}(a) \end{pmatrix},$$

and we have

$$D^2 f(a)(u, v) = u^\top \nabla^2 f(a) v = u \cdot \nabla^2 f(a)v = \nabla^2 f(a)u \cdot v,$$

for all $u, v \in \mathbb{R}^n$. Then, we have the following three formulations of the formula of Taylor–Young of order 2:

$$\begin{aligned} f(a + h) &= f(a) + Df(a)(h) + \frac{1}{2} D^2 f(a)(h, h) + \|h\|^2 \epsilon(h) \\ f(a + h) &= f(a) + \nabla f(a) \cdot h + \frac{1}{2} (h \cdot \nabla^2 f(a)h) + (h \cdot h) \epsilon(h) \\ f(a + h) &= f(a) + (\nabla f(a))^\top h + \frac{1}{2} (h^\top \nabla^2 f(a) h) + (h^\top h) \epsilon(h). \end{aligned}$$

with $\lim_{h \rightarrow 0} \epsilon(h) = 0$.

One should keep in mind that only the first formula is intrinsic (i.e., does not depend on the choice of a basis), whereas the other two depend on the basis and the inner product chosen

on \mathbb{R}^n . As an exercise, the reader should write similar formulae for the Taylor–MacLaurin formula of order 2.

Another application of Taylor’s formula is the derivation of a formula which gives the m -th derivative of the composition of two functions, usually known as “Faà di Bruno’s formula.” This formula is useful when dealing with geometric continuity of splines curves and surfaces.

Proposition 39.27. *Given any normed affine space E , for any function $f: \mathbb{R} \rightarrow \mathbb{R}$ and any function $g: \mathbb{R} \rightarrow E$, for any $a \in \mathbb{R}$, letting $b = f(a)$, $f^{(i)}(a) = D^i f(a)$, and $g^{(i)}(b) = D^i g(b)$, for any $m \geq 1$, if $f^{(i)}(a)$ and $g^{(i)}(b)$ exist for all i , $1 \leq i \leq m$, then $(g \circ f)^{(m)}(a) = D^m(g \circ f)(a)$ exists and is given by the following formula:*

$$(g \circ f)^{(m)}(a) = \sum_{0 \leq j \leq m} \sum_{\substack{i_1+i_2+\dots+i_m=j \\ i_1+2i_2+\dots+mi_m=m \\ i_1, i_2, \dots, i_m \geq 0}} \frac{m!}{i_1! \dots i_m!} g^{(j)}(b) \left(\frac{f^{(1)}(a)}{1!} \right)^{i_1} \dots \left(\frac{f^{(m)}(a)}{m!} \right)^{i_m}.$$

When $m = 1$, the above simplifies to the familiar formula

$$(g \circ f)'(a) = g'(b)f'(a),$$

and for $m = 2$, we have

$$(g \circ f)^{(2)}(a) = g^{(2)}(b)(f^{(1)}(a))^2 + g^{(1)}(b)f^{(2)}(a).$$

39.8 Vector Fields, Covariant Derivatives, Lie Brackets

In this section, we briefly consider vector fields and covariant derivatives of vector fields. Such derivatives play an important role in continuous mechanics. Given a normed affine space (E, \overrightarrow{E}) , a *vector field over (E, \overrightarrow{E})* is a function $X: E \rightarrow \overrightarrow{E}$. Intuitively, a vector field assigns a vector to every point in E . Such vectors could be forces, velocities, accelerations, etc.

Given two vector fields X, Y defined on some open subset Ω of E , for every point $a \in \Omega$, we would like to define the derivative of X with respect to Y at a . This is a type of directional derivative that gives the variation of X as we move along Y , and we denote it by $D_Y X(a)$. The derivative $D_Y X(a)$ is defined as follows.

Definition 39.20. Let (E, \overrightarrow{E}) be a normed affine space. Given any open subset Ω of E , given any two vector fields X and Y defined over Ω , for any $a \in \Omega$, the *covariant derivative (or Lie derivative) of X w.r.t. the vector field Y at a* , denoted by $D_Y X(a)$, is the limit (if it exists)

$$\lim_{t \rightarrow 0, t \in U} \frac{X(a + tY(a)) - X(a)}{t},$$

where $U = \{t \in \mathbb{R} \mid a + tY(a) \in \Omega, t \neq 0\}$.

If Y is a constant vector field, it is immediately verified that the map

$$X \mapsto D_Y X(a)$$

is a linear map called the *derivative* of the vector field X , and denoted by $D_X(a)$. If $f: E \rightarrow \mathbb{R}$ is a function, we define $D_Y f(a)$ as the limit (if it exists)

$$\lim_{t \rightarrow 0, t \in U} \frac{f(a + tY(a)) - f(a)}{t},$$

where $U = \{t \in \mathbb{R} \mid a + tY(a) \in \Omega, t \neq 0\}$. It is the *directional derivative of f w.r.t. the vector field Y at a* , and it is also often denoted by $Y(f)(a)$, or $Y(f)_a$.

From now on, we assume that all the vector fields and all the functions under consideration are smooth (C^∞). The set $C^\infty(\Omega)$ of smooth C^∞ -functions $f: \Omega \rightarrow \mathbb{R}$ is a ring. Given a smooth vector field X and a smooth function f (both over Ω), the vector field fX is defined such that $(fX)(a) = f(a)X(a)$, and it is immediately verified that it is smooth. Thus, the set $\mathcal{X}(\Omega)$ of smooth vector fields over Ω is a $C^\infty(\Omega)$ -module.

The following proposition is left as an exercise. It shows that $D_Y X(a)$ is a \mathbb{R} -bilinear map on $\mathcal{X}(\Omega)$, is $C^\infty(\Omega)$ -linear in Y , and satisfies the Leibniz derivation rules with respect to X .

Proposition 39.28. *The covariant derivative $D_Y X(a)$ satisfies the following properties:*

$$\begin{aligned} D_{(Y_1+Y_2)} X(a) &= D_{Y_1} X(a) + D_{Y_2} X(a), \\ D_{fY} X(a) &= f(a)D_Y X(a), \\ D_Y(X_1 + X_2)(a) &= D_Y X_1(a) + D_Y X_2(a), \\ D_Y fX(a) &= D_Y f(a)X(a) + f(a)D_Y X(a), \end{aligned}$$

where X, Y, X_1, X_2, Y_1, Y_2 are smooth vector fields over Ω , and $f: E \rightarrow \mathbb{R}$ is a smooth function.

In differential geometry, the above properties are taken as the axioms of *affine connections*, in order to define covariant derivatives of vector fields over manifolds. In many cases, the vector field Y is the tangent field of some smooth curve $\gamma:]-\eta, \eta[\rightarrow E$. If so, the following proposition holds.

Proposition 39.29. *Given a smooth curve $\gamma:]-\eta, \eta[\rightarrow E$, letting Y be the vector field defined on $\gamma([-\eta, \eta])$ such that*

$$Y(\gamma(u)) = \frac{d\gamma}{dt}(u),$$

for any vector field X defined on $\gamma([-\eta, \eta])$, we have

$$D_Y X(a) = \frac{d}{dt} \left[X(\gamma(t)) \right] (0),$$

where $a = \gamma(0)$.

The derivative $D_Y X(a)$ is thus the derivative of the vector field X along the curve γ , and it is called the *covariant derivative of X along γ* .

Given an affine frame $(O, (u_1, \dots, u_n))$ for (E, \overrightarrow{E}) , it is easily seen that the covariant derivative $D_Y X(a)$ is expressed as follows:

$$D_Y X(a) = \sum_{i=1}^n \sum_{j=1}^n \left(Y_j \frac{\partial X_i}{\partial x_j} \right)(a) e_i.$$

Generally, $D_Y X(a) \neq D_X Y(a)$. The quantity

$$[X, Y] = D_X Y - D_Y X$$

is called the *Lie bracket* of the vector fields X and Y . The Lie bracket plays an important role in differential geometry. In terms of coordinates,

$$[X, Y] = \sum_{i=1}^n \sum_{j=1}^n \left(X_j \frac{\partial Y_i}{\partial x_j} - Y_j \frac{\partial X_i}{\partial x_j} \right) e_i.$$

39.9 Futher Readings

A thorough treatment of differential calculus can be found in Munkres [130], Lang [112], Schwartz [151], Cartan [34], and Avez [9]. The techniques of differential calculus have many applications, especially to the geometry of curves and surfaces and to differential geometry in general. For this, we recommend do Carmo [52, 53] (two beautiful classics on the subject), Kreyszig [106], Stoker [166], Gray [81], Berger and Gostiaux [13], Milnor [126], Lang [110], Warner [186] and Choquet-Bruhat [38].

39.10 Summary

The main concepts and results of this chapter are listed below:

- *Directional derivative* ($D_u f(a)$).
- *Total derivative, Fréchet derivative, derivative, total differential, differential* ($df(a)$, df_a).
- *Partial derivatives.*
- *Affine functions.*
- The *chain rule*.
- *Jacobian matrices* ($J(f)(a)$), *Jacobians*.

- Gradient of a function ($\text{grad } f(a)$, $\nabla f(a)$).
- Mean value theorem.
- C^0 -functions, C^1 -functions.
- The implicit function theorem.
- Local homeomorphisms, local diffeomorphisms, diffeomorphisms.
- The inverse function theorem.
- Immersions, submersions.
- Second-order and higher-order derivatives.
- Schwarz's lemma.
- Hessian matrix.
- C^∞ -functions, smooth functions.
- Taylor–Young's formula.
- Generalized mean value theorem.
- Taylor–MacLaurin's formula.
- Taylor's formula with integral remainder.
- Faà di Bruno's formula.

39.11 Problems

Problem 39.1. Let $f: M_n(\mathbb{R}) \rightarrow M_n(\mathbb{R})$ be the function defined on $n \times n$ matrices by

$$f(A) = A^2.$$

Prove that

$$Df_A(H) = AH + HA,$$

for all $A, H \in M_n(\mathbb{R})$.

Problem 39.2. Let $f: M_n(\mathbb{R}) \rightarrow M_n(\mathbb{R})$ be the function defined on $n \times n$ matrices by

$$f(A) = A^3.$$

Prove that

$$Df_A(H) = A^2H + AHA + HA^2,$$

for all $A, H \in M_n(\mathbb{R})$.

Problem 39.3. If $f: M_n(\mathbb{R}) \rightarrow M_n(\mathbb{R})$ and $g: M_n(\mathbb{R}) \rightarrow M_n(\mathbb{R})$ are differentiable matrix functions, prove that

$$d(fg)_A(B) = df_A(B)g(A) + f(A)dg_A(B),$$

for all $A, B \in M_n(\mathbb{R})$.

Problem 39.4. Recall that $\mathfrak{so}(3)$ denotes the vector space of real skew-symmetric $n \times n$ matrices ($B^\top = -B$). Let $C: \mathfrak{so}(n) \rightarrow M_n(\mathbb{R})$ be the function given by

$$C(B) = (I - B)(I + B)^{-1}.$$

(1) Prove that if B is skew-symmetric, then $I - B$ and $I + B$ are invertible, and so C is well-defined. Prove that

(2) Prove that

$$dC(B)(A) = -[I + (I - B)(I + B)^{-1}]A(I + B)^{-1} = -2(I + B)^{-1}A(I + B)^{-1}.$$

(3) Prove that $dC(B)$ is injective for every skew-symmetric matrix B .

Problem 39.5. Prove that

$$\begin{aligned} d^m C_B(H_1, \dots, H_m) \\ = 2(-1)^m \sum_{\pi \in \mathfrak{S}_m} (I + B)^{-1} H_{\pi(1)}(I + B)^{-1} H_{\pi(2)}(I + B)^{-1} \cdots (I + B)^{-1} H_{\pi(m)}(I + B)^{-1}. \end{aligned}$$

Problem 39.6. Consider the function g defined for all $A \in \mathbf{GL}(n, \mathbb{R})$, that is, all $n \times n$ real invertible matrices, given by

$$g(A) = \det(A).$$

(1) Prove that

$$dg_A(X) = \det(A)\text{tr}(A^{-1}X),$$

for all $n \times n$ real matrices X .

(2) Consider the function f defined for all $A \in \mathbf{GL}^+(n, \mathbb{R})$, that is, $n \times n$ real invertible matrices of positive determinants, given by

$$f(A) = \log g(A) = \log \det(A).$$

Prove that

$$\begin{aligned} df_A(X) &= \text{tr}(A^{-1}X) \\ D^2 f(A)(X_1, X_2) &= -\text{tr}(A^{-1}X_1 A^{-1}X_2), \end{aligned}$$

for all $n \times n$ real matrices X, X_1, X_2 .

(3) Prove that

$$D^m f(A)(X_1, \dots, X_m) = (-1)^{m-1} \sum_{\sigma \in \mathfrak{S}_{m-1}} \text{tr}(A^{-1}X_1 A^{-1}X_{\sigma(1)+1} A^{-1}X_{\sigma(2)+1} \cdots A^{-1}X_{\sigma(m-1)+1})$$

for any $m \geq 1$, where X_1, \dots, X_m are any $n \times n$ real matrices.

Part VI

Preliminaries for Optimization Theory

Chapter 40

Extrema of Real-Valued Functions

This chapter deals with extrema of real-valued functions. In most optimization problems, we need to find necessary conditions for a function $J: \Omega \rightarrow \mathbb{R}$ to have a local extremum with respect to a subset U of Ω (where Ω is open). This can be done in two cases:

- (1) The set U is defined by a set of equations,

$$U = \{x \in \Omega \mid \varphi_i(x) = 0, \quad 1 \leq i \leq m\},$$

where the functions $\varphi_i: \Omega \rightarrow \mathbb{R}$ are continuous (and usually differentiable).

- (2) The set U is defined by a set of inequalities,

$$U = \{x \in \Omega \mid \varphi_i(x) \leq 0, \quad 1 \leq i \leq m\},$$

where the functions $\varphi_i: \Omega \rightarrow \mathbb{R}$ are continuous (and usually differentiable).

In (1), the equations $\varphi_i(x) = 0$ are called *equality constraints*, and in (2), the inequalities $\varphi_i(x) \leq 0$ are called *inequality constraints*. The case of equality constraints is much easier to deal with and is treated in this chapter.

If the functions φ_i are convex and Ω is convex, then U is convex. This is a very important case that we discuss later. In particular, if the functions φ_i are affine, then the equality constraints can be written as $Ax = b$, and the inequality constraints as $Ax \leq b$, for some $m \times n$ matrix A and some vector $b \in \mathbb{R}^m$. We will also discuss the case of affine constraints later.

In the case of equality constraints, a necessary condition for a local extremum with respect to U can be given in terms of *Lagrange multipliers*. In the case of inequality constraints, there is also a necessary condition for a local extremum with respect to U in terms of generalized Lagrange multipliers and the *Karush–Kuhn–Tucker* conditions. This will be discussed in Chapter 50.

40.1 Local Extrema, Constrained Local Extrema, and Lagrange Multipliers

Let $J: E \rightarrow \mathbb{R}$ be a real-valued function defined on a normed vector space E (or more generally, any topological space). Ideally we would like to find where the function J reaches a minimum or a maximum value, at least locally. In this chapter we will usually use the notations $dJ(u)$ or $J'(u)$ (or dJ_u or J'_u) for the derivative of J at u , instead of $DJ(u)$. Our presentation follows very closely that of Ciarlet [41] (Chapter 7), which we find to be one of the clearest.

Definition 40.1. If $J: E \rightarrow \mathbb{R}$ is a real-valued function defined on a normed vector space E , we say that J has a *local minimum* (or *relative minimum*) at the point $u \in E$ if there is some open subset $W \subseteq E$ containing u such that

$$J(u) \leq J(w) \quad \text{for all } w \in W.$$

Similarly, we say that J has a *local maximum* (or *relative maximum*) at the point $u \in E$ if there is some open subset $W \subseteq E$ containing u such that

$$J(u) \geq J(w) \quad \text{for all } w \in W.$$

In either case, we say that J has a *local extremum* (or *relative extremum*) at u . We say that J has a *strict local minimum* (resp. *strict local maximum*) at the point $u \in E$ if there is some open subset $W \subseteq E$ containing u such that

$$J(u) < J(w) \quad \text{for all } w \in W - \{u\}$$

(resp.

$$J(u) > J(w) \quad \text{for all } w \in W - \{u\}).$$

By abuse of language, we often say that the point u itself “is a local minimum” or a “local maximum,” even though, strictly speaking, this does not make sense.

We begin with a well-known necessary condition for a local extremum.

Proposition 40.1. *Let E be a normed vector space and let $J: \Omega \rightarrow \mathbb{R}$ be a function, with Ω some open subset of E . If the function J has a local extremum at some point $u \in \Omega$ and if J is differentiable at u , then*

$$dJ_u = J'(u) = 0.$$

Proof. Pick any $v \in E$. Since Ω is open, for t small enough we have $u + tv \in \Omega$, so there is an open interval $I \subseteq \mathbb{R}$ such that the function φ given by

$$\varphi(t) = J(u + tv)$$

for all $t \in I$ is well-defined. By applying the chain rule, we see that φ is differentiable at $t = 0$, and we get

$$\varphi'(0) = dJ_u(v).$$

Without loss of generality, assume that u is a local minimum. Then we have

$$\varphi'(0) = \lim_{t \rightarrow 0^-} \frac{\varphi(t) - \varphi(0)}{t} \leq 0$$

and

$$\varphi'(0) = \lim_{t \rightarrow 0^+} \frac{\varphi(t) - \varphi(0)}{t} \geq 0,$$

which shows that $\varphi'(0) = dJ_u(v) = 0$. As $v \in E$ is arbitrary, we conclude that $dJ_u = 0$. \square

Definition 40.2. A point $u \in \Omega$ such that $J'(u) = 0$ is called a *critical point* of J .

If $E = \mathbb{R}^n$, then the condition $dJ_u = 0$ is equivalent to the system

$$\begin{aligned} \frac{\partial J}{\partial x_1}(u_1, \dots, u_n) &= 0 \\ &\vdots \\ \frac{\partial J}{\partial x_n}(u_1, \dots, u_n) &= 0. \end{aligned}$$

The condition of Proposition 40.1 is only a *necessary* condition for the existence of an extremum, but not a sufficient condition.

Here are some counter-examples. If $f: \mathbb{R} \rightarrow \mathbb{R}$ is the function given by $f(x) = x^3$, since $f'(x) = 3x^2$, we have $f'(0) = 0$, but 0 is neither a minimum nor a maximum of f as evidenced by the graph shown in Figure 40.1.

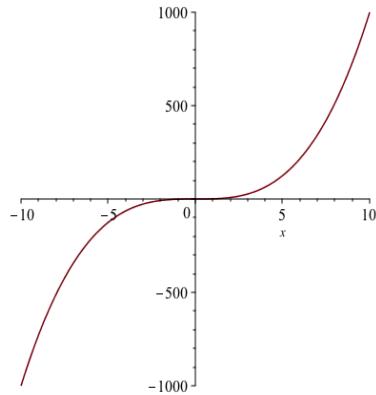

Figure 40.1: The graph of $f(x) = x^3$. Note that $x = 0$ is a saddle point and not a local extremum.

If $g: \mathbb{R}^2 \rightarrow \mathbb{R}$ is the function given by $g(x, y) = x^2 - y^2$, then $g'_{(x,y)} = (2x, -2y)$, so $g'_{(0,0)} = (0, 0)$, yet near $(0, 0)$ the function g takes negative and positive values. See Figure 40.2.

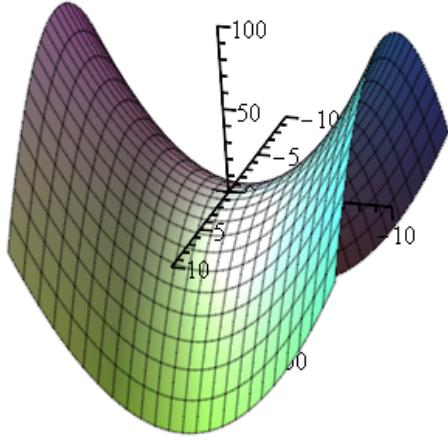

Figure 40.2: The graph of $g(x, y) = x^2 - y^2$. Note that $(0, 0)$ is a saddle point and not a local extremum.

It is very important to note that the hypothesis that Ω is open is crucial for the validity of Proposition 40.1.

For example, if J is the identity function on \mathbb{R} and $U = [0, 1]$, a closed subset, then $J'(x) = 1$ for all $x \in [0, 1]$, even though J has a minimum at $x = 0$ and a maximum at $x = 1$.

In many practical situations, we need to look for local extrema of a function J under additional constraints. This situation can be formalized conveniently as follows. We have a function $J: \Omega \rightarrow \mathbb{R}$ defined on some open subset Ω of a normed vector space, but we also have some subset U of Ω , and we are looking for the local extrema of J with respect to the set U .

The elements $u \in U$ are often called *feasible solutions* of the optimization problem consisting in finding the local extrema of some objective function J with respect to some subset U of Ω defined by a set of constraints. Note that in most cases, U is not open. In fact, U is usually closed.

Definition 40.3. If $J: \Omega \rightarrow \mathbb{R}$ is a real-valued function defined on some open subset Ω of a normed vector space E and if U is some subset of Ω , we say that J has a *local minimum* (or *relative minimum*) at the point $u \in U$ with respect to U if there is some open subset $W \subseteq \Omega$ containing u such that

$$J(u) \leq J(w) \quad \text{for all } w \in U \cap W.$$

Similarly, we say that J has a *local maximum* (or *relative maximum*) at the point $u \in U$ with respect to U if there is some open subset $W \subseteq \Omega$ containing u such that

$$J(u) \geq J(w) \quad \text{for all } w \in U \cap W.$$

In either case, we say that J has a *local extremum* at u with respect to U .

In order to find necessary conditions for a function $J: \Omega \rightarrow \mathbb{R}$ to have a local extremum with respect to a subset U of Ω (where Ω is open), we need to somehow incorporate the definition of U into these conditions. This can be done in two cases:

- (1) The set U is defined by a set of equations,

$$U = \{x \in \Omega \mid \varphi_i(x) = 0, 1 \leq i \leq m\},$$

where the functions $\varphi_i: \Omega \rightarrow \mathbb{R}$ are continuous (and usually differentiable).

- (2) The set U is defined by a set of inequalities,

$$U = \{x \in \Omega \mid \varphi_i(x) \leq 0, 1 \leq i \leq m\},$$

where the functions $\varphi_i: \Omega \rightarrow \mathbb{R}$ are continuous (and usually differentiable).

In (1), the equations $\varphi_i(x) = 0$ are called *equality constraints*, and in (2), the inequalities $\varphi_i(x) \leq 0$ are called *inequality constraints*.

An inequality constraint of the form $\varphi_i(x) \geq 0$ is equivalent to the inequality constraint $-\varphi_i(x) \leq 0$. An equality constraint $\varphi_i(x) = 0$ is equivalent to the conjunction of the two inequality constraints $\varphi_i(x) \leq 0$ and $-\varphi_i(x) \leq 0$, so the case of inequality constraints subsumes the case of equality constraints. However, the case of equality constraints is easier to deal with, and in this chapter we will restrict our attention to this case.

If the functions φ_i are convex and Ω is convex, then U is convex. This is a very important case that we will discuss later. In particular, if the functions φ_i are affine, then the equality constraints can be written as $Ax = b$, and the inequality constraints as $Ax \leq b$, for some $m \times n$ matrix A and some vector $b \in \mathbb{R}^m$. We will also discuss the case of affine constraints later.

In the case of equality constraints, a necessary condition for a local extremum with respect to U can be given in terms of *Lagrange multipliers*. In the case of inequality constraints, there is also a necessary condition for a local extremum with respect to U in terms of generalized Lagrange multipliers and the *Karush–Kuhn–Tucker* conditions. This will be discussed in Chapter 50.

We begin by considering the case where $\Omega \subseteq E_1 \times E_2$ is an open subset of a product of normed vector spaces and where U is the zero locus of some continuous function $\varphi: \Omega \rightarrow E_2$, which means that

$$U = \{(u_1, u_2) \in \Omega \mid \varphi(u_1, u_2) = 0\}.$$

For the sake of brevity, we say that J has a *constrained local extremum* at u instead of saying that J has a *local extremum* at the point $u \in U$ with respect to U .

In most applications, we have $E_1 = \mathbb{R}^{n-m}$ and $E_2 = \mathbb{R}^m$ for some integers m, n such that $1 \leq m < n$, Ω is an open subset of \mathbb{R}^n , $J: \Omega \rightarrow \mathbb{R}$, and we have m functions $\varphi_i: \Omega \rightarrow \mathbb{R}$ defining the subset

$$U = \{v \in \Omega \mid \varphi_i(v) = 0, 1 \leq i \leq m\}.$$

Fortunately, there is a necessary condition for constrained local extrema in terms of *Lagrange multipliers*.

Theorem 40.2. (*Necessary condition for a constrained extremum in terms of Lagrange multipliers*) Let Ω be an open subset of \mathbb{R}^n , consider m C^1 -functions $\varphi_i: \Omega \rightarrow \mathbb{R}$ (with $1 \leq m < n$), let

$$U = \{v \in \Omega \mid \varphi_i(v) = 0, 1 \leq i \leq m\},$$

and let $u \in U$ be a point such that the derivatives $d\varphi_i(u) \in \mathcal{L}(\mathbb{R}^n; \mathbb{R})$ are linearly independent; equivalently, assume that the $m \times n$ matrix $((\partial\varphi_i/\partial x_j)(u))$ has rank m . If $J: \Omega \rightarrow \mathbb{R}$ is a function which is differentiable at $u \in U$ and if J has a local constrained extremum at u , then there exist m numbers $\lambda_i(u) \in \mathbb{R}$, uniquely defined, such that

$$dJ(u) + \lambda_1(u)d\varphi_1(u) + \cdots + \lambda_m(u)d\varphi_m(u) = 0;$$

equivalently,

$$\nabla J(u) + \lambda_1(u)\nabla\varphi_1(u) + \cdots + \lambda_m(u)\nabla\varphi_m(u) = 0.$$

Theorem 40.2 will be proven as a corollary of Theorem 40.4, which gives a more general formulation that applies to the situation where E_1 is an infinite-dimensional Banach space. To simplify the exposition we postpone a discussion of this theorem until we have presented several examples illustrating the method of Lagrange multipliers.

Definition 40.4. The numbers $\lambda_i(u)$ involved in Theorem 40.2 are called the *Lagrange multipliers* associated with the constrained extremum u (again, with some minor abuse of language).

The linear independence of the linear forms $d\varphi_i(u)$ is equivalent to the fact that the Jacobian matrix $((\partial\varphi_i/\partial x_j)(u))$ of $\varphi = (\varphi_1, \dots, \varphi_m)$ at u has rank m . If $m = 1$, the linear independence of the $d\varphi_i(u)$ reduces to the condition $\nabla\varphi_1(u) \neq 0$.

A fruitful way to reformulate the use of Lagrange multipliers is to introduce the notion of the *Lagrangian* associated with our constrained extremum problem.

Definition 40.5. The *Lagrangian* associated with our constrained extremum problem is the function $L: \Omega \times \mathbb{R}^m \rightarrow \mathbb{R}$ given by

$$L(v, \lambda) = J(v) + \lambda_1\varphi_1(v) + \cdots + \lambda_m\varphi_m(v),$$

with $\lambda = (\lambda_1, \dots, \lambda_m)$.

We have the following simple but important proposition.

Proposition 40.3. *There exists some $\mu = (\mu_1, \dots, \mu_m)$ and some $u \in U$ such that*

$$dJ(u) + \mu_1 d\varphi_1(u) + \cdots + \mu_m d\varphi_m(u) = 0$$

if and only if

$$dL(u, \mu) = 0,$$

or equivalently

$$\nabla L(u, \mu) = 0;$$

that is, iff (u, μ) is a critical point of the Lagrangian L .

Proof. Indeed $dL(u, \mu) = 0$ is equivalent to

$$\begin{aligned} \frac{\partial L}{\partial v}(u, \mu) &= 0 \\ \frac{\partial L}{\partial \lambda_1}(u, \mu) &= 0 \\ &\vdots \\ \frac{\partial L}{\partial \lambda_m}(u, \mu) &= 0, \end{aligned}$$

and since

$$\frac{\partial L}{\partial v}(u, \mu) = dJ(u) + \mu_1 d\varphi_1(u) + \cdots + \mu_m d\varphi_m(u)$$

and

$$\frac{\partial L}{\partial \lambda_i}(u, \mu) = \varphi_i(u),$$

we get

$$dJ(u) + \mu_1 d\varphi_1(u) + \cdots + \mu_m d\varphi_m(u) = 0$$

and

$$\varphi_1(u) = \cdots = \varphi_m(u) = 0,$$

that is, $u \in U$. The converse is proven in a similar fashion (essentially by reversing the argument). \square

If we write out explicitly the condition

$$dJ(u) + \mu_1 d\varphi_1(u) + \cdots + \mu_m d\varphi_m(u) = 0,$$

we get the $n \times m$ system

$$\begin{aligned} \frac{\partial J}{\partial x_1}(u) + \lambda_1 \frac{\partial \varphi_1}{\partial x_1}(u) + \cdots + \lambda_m \frac{\partial \varphi_m}{\partial x_1}(u) &= 0 \\ &\vdots \\ \frac{\partial J}{\partial x_n}(u) + \lambda_1 \frac{\partial \varphi_1}{\partial x_n}(u) + \cdots + \lambda_m \frac{\partial \varphi_m}{\partial x_n}(u) &= 0, \end{aligned}$$

and it is important to note that the matrix of this system is the *transpose* of the Jacobian matrix of φ at u . If we write $\text{Jac}(\varphi)(u) = ((\partial \varphi_i / \partial x_j)(u))$ for the Jacobian matrix of φ (at u), then the above system is written in matrix form as

$$\nabla J(u) + (\text{Jac}(\varphi)(u))^T \lambda = 0,$$

where λ is viewed as a column vector, and the Lagrangian is equal to

$$L(u, \lambda) = J(u) + (\varphi_1(u), \dots, \varphi_m(u))\lambda.$$

The beauty of the Lagrangian is that the constraints $\{\varphi_i(v) = 0\}$ have been incorporated into the function $L(v, \lambda)$, and that the necessary condition for the existence of a constrained local extremum of J is reduced to the necessary condition for the existence of a local extremum of the *unconstrained* L .

However, one should be careful to check that the assumptions of Theorem 40.2 are satisfied (in particular, the linear independence of the linear forms $d\varphi_i$).

Example 40.1. For example, let $J: \mathbb{R}^3 \rightarrow \mathbb{R}$ be given by

$$J(x, y, z) = x + y + z^2$$

and $g: \mathbb{R}^3 \rightarrow \mathbb{R}$ by

$$g(x, y, z) = x^2 + y^2.$$

Since $g(x, y, z) = 0$ iff $x = y = 0$, we have $U = \{(0, 0, z) \mid z \in \mathbb{R}\}$ and the restriction of J to U is given by

$$J(0, 0, z) = z^2,$$

which has a minimum for $z = 0$. However, a “blind” use of Lagrange multipliers would require that there is some λ so that

$$\frac{\partial J}{\partial x}(0, 0, z) = \lambda \frac{\partial g}{\partial x}(0, 0, z), \quad \frac{\partial J}{\partial y}(0, 0, z) = \lambda \frac{\partial g}{\partial y}(0, 0, z), \quad \frac{\partial J}{\partial z}(0, 0, z) = \lambda \frac{\partial g}{\partial z}(0, 0, z),$$

and since

$$\frac{\partial g}{\partial x}(x, y, z) = 2x, \quad \frac{\partial g}{\partial y}(x, y, z) = 2y, \quad \frac{\partial g}{\partial z}(0, 0, z) = 0,$$

the partial derivatives above all vanish for $x = y = 0$, so at a local extremum we should also have

$$\frac{\partial J}{\partial x}(0, 0, z) = 0, \quad \frac{\partial J}{\partial y}(0, 0, z) = 0, \quad \frac{\partial J}{\partial z}(0, 0, z) = 0,$$

but this is absurd since

$$\frac{\partial J}{\partial x}(x, y, z) = 1, \quad \frac{\partial J}{\partial y}(x, y, z) = 1, \quad \frac{\partial J}{\partial z}(x, y, z) = 2z.$$

The reader should enjoy finding the reason for the flaw in the argument.

One should also keep in mind that Theorem 40.2 gives only a **necessary condition**. The (u, λ) may *not* correspond to local extrema! Thus, it is always necessary to analyze the local behavior of J near a critical point u . This is generally difficult, but in the case where J is affine or quadratic and the constraints are affine or quadratic, this is possible (although not always easy).

Example 40.2. Let us apply the above method to the following example in which $E_1 = \mathbb{R}$, $E_2 = \mathbb{R}$, $\Omega = \mathbb{R}^2$, and

$$\begin{aligned} J(x_1, x_2) &= -x_2 \\ \varphi(x_1, x_2) &= x_1^2 + x_2^2 - 1. \end{aligned}$$

Observe that

$$U = \{(x_1, x_2) \in \mathbb{R}^2 \mid x_1^2 + x_2^2 = 1\}$$

is the unit circle, and since

$$\nabla \varphi(x_1, x_2) = \begin{pmatrix} 2x_1 \\ 2x_2 \end{pmatrix},$$

it is clear that $\nabla \varphi(x_1, x_2) \neq 0$ for every point $= (x_1, x_2)$ on the unit circle. If we form the Lagrangian

$$L(x_1, x_2, \lambda) = -x_2 + \lambda(x_1^2 + x_2^2 - 1),$$

Theorem 40.2 says that a necessary condition for J to have a constrained local extremum is that $\nabla L(x_1, x_2, \lambda) = 0$, so the following equations must hold:

$$\begin{aligned} 2\lambda x_1 &= 0 \\ -1 + 2\lambda x_2 &= 0 \\ x_1^2 + x_2^2 &= 1. \end{aligned}$$

The second equation implies that $\lambda \neq 0$, and then the first yields $x_1 = 0$, so the third yields $x_2 = \pm 1$, and we get two solutions:

$$\begin{aligned} \lambda = \frac{1}{2}, \quad & (x_1, x_2) = (0, 1) \\ \lambda = -\frac{1}{2}, \quad & (x'_1, x'_2) = (0, -1). \end{aligned}$$

We can check immediately that the first solution is a minimum and the second is a maximum. The reader should look for a geometric interpretation of this problem.

Example 40.3. Let us now consider the case in which J is a quadratic function of the form

$$J(v) = \frac{1}{2}v^\top Av - v^\top b,$$

where A is an $n \times n$ symmetric matrix, $b \in \mathbb{R}^n$, and the constraints are given by a linear system of the form

$$Cv = d,$$

where C is an $m \times n$ matrix with $m < n$ and $d \in \mathbb{R}^m$. We also assume that C has rank m . In this case the function φ is given by

$$\varphi(v) = (Cv - d)^\top,$$

because we view $\varphi(v)$ as a row vector (and v as a column vector), and since

$$d\varphi(v)(w) = C^\top w,$$

the condition that the Jacobian matrix of φ at u have rank m is satisfied. The Lagrangian of this problem is

$$L(v, \lambda) = \frac{1}{2}v^\top Av - v^\top b + (Cv - d)^\top \lambda = \frac{1}{2}v^\top Av - v^\top b + \lambda^\top (Cv - d),$$

where λ is viewed as a column vector. Now because A is a symmetric matrix, it is easy to show that

$$\nabla L(v, \lambda) = \begin{pmatrix} Av - b + C^\top \lambda \\ Cv - d \end{pmatrix}.$$

Therefore, the necessary condition for constrained local extrema is

$$\begin{aligned} Av + C^\top \lambda &= b \\ Cv &= d, \end{aligned}$$

which can be expressed in matrix form as

$$\begin{pmatrix} A & C^\top \\ C & 0 \end{pmatrix} \begin{pmatrix} v \\ \lambda \end{pmatrix} = \begin{pmatrix} b \\ d \end{pmatrix},$$

where the matrix of the system is a symmetric matrix. We should not be surprised to find the system discussed later in Chapter 42, except for some renaming of the matrices and vectors involved. As we will show in Section 42.2, the function J has a minimum iff A is positive definite, so in general, if A is only a symmetric matrix, the critical points of the Lagrangian do *not* correspond to extrema of J .

Remark: If the Jacobian matrix $\text{Jac}(\varphi)(v) = ((\partial\varphi_i/\partial x_j)(v))$ has rank m for all $v \in U$ (which is equivalent to the linear independence of the linear forms $d\varphi_i(v)$), then we say that $0 \in \mathbb{R}^m$ is a *regular value* of φ . In this case, it is known that

$$U = \{v \in \Omega \mid \varphi(v) = 0\}$$

is a *smooth submanifold of dimension $n - m$ of \mathbb{R}^n* . Furthermore, the set

$$T_v U = \{w \in \mathbb{R}^n \mid d\varphi_i(v)(w) = 0, 1 \leq i \leq m\} = \bigcap_{i=1}^m \text{Ker } d\varphi_i(v)$$

is the *tangent space* to U at v (a vector space of dimension $n - m$). Then, the condition

$$dJ(v) + \mu_1 d\varphi_1(v) + \cdots + \mu_m d\varphi_m(v) = 0$$

implies that $dJ(v)$ vanishes on the tangent space $T_v U$. Conversely, if $dJ(v)(w) = 0$ for all $w \in T_v U$, this means that $dJ(v)$ is orthogonal (in the sense of Definition 11.3) to $T_v U$. Since (by Theorem 11.4 (b)) the orthogonal of $T_v U$ is the space of linear forms spanned by $d\varphi_1(v), \dots, d\varphi_m(v)$, it follows that $dJ(v)$ must be a linear combination of the $d\varphi_i(v)$. Therefore, when 0 is a regular value of φ , Theorem 40.2 asserts that if $u \in U$ is a local extremum of J , then $dJ(u)$ must vanish on the tangent space $T_u U$. We can say even more. The subset $Z(J)$ of Ω given by

$$Z(J) = \{v \in \Omega \mid J(v) = J(u)\}$$

(the *level set of level $J(u)$*) is a hypersurface in Ω , and if $dJ(u) \neq 0$, the zero locus of $dJ(u)$ is the tangent space $T_u Z(J)$ to $Z(J)$ at u (a vector space of dimension $n - 1$), where

$$T_u Z(J) = \{w \in \mathbb{R}^n \mid dJ(u)(w) = 0\}.$$

Consequently, Theorem 40.2 asserts that

$$T_u U \subseteq T_u Z(J);$$

this is a geometric condition.

We now return to the general situation where E_1 and E_2 may be infinite-dimensional normed vector spaces (with E_1 a Banach space) and we state and prove the following general result about the method of Lagrange multipliers.

Theorem 40.4. (*Necessary condition for a constrained extremum*) Let $\Omega \subseteq E_1 \times E_2$ be an open subset of a product of normed vector spaces, with E_1 a Banach space (E_1 is complete), let $\varphi: \Omega \rightarrow E_2$ be a C^1 -function (which means that $d\varphi(\omega)$ exists and is continuous for all $\omega \in \Omega$), and let

$$U = \{(u_1, u_2) \in \Omega \mid \varphi(u_1, u_2) = 0\}.$$

Moreover, let $u = (u_1, u_2) \in U$ be a point such that

$$\frac{\partial \varphi}{\partial x_2}(u_1, u_2) \in \mathcal{L}(E_2; E_2) \quad \text{and} \quad \left(\frac{\partial \varphi}{\partial x_2}(u_1, u_2) \right)^{-1} \in \mathcal{L}(E_2; E_2),$$

and let $J: \Omega \rightarrow \mathbb{R}$ be a function which is differentiable at u . If J has a constrained local extremum at u , then there is a continuous linear form $\Lambda(u) \in \mathcal{L}(E_2; \mathbb{R})$ such that

$$dJ(u) + \Lambda(u) \circ d\varphi(u) = 0.$$

Proof. The plan of attack is to use the implicit function theorem; Theorem 39.14. Observe that the assumptions of Theorem 39.14 are indeed met. Therefore, there exist some open subsets $U_1 \subseteq E_1$, $U_2 \subseteq E_2$, and a continuous function $g: U_1 \rightarrow U_2$ with $(u_1, u_2) \in U_1 \times U_2 \subseteq \Omega$ and such that

$$\varphi(v_1, g(v_1)) = 0$$

for all $v_1 \in U_1$. Moreover, g is differentiable at $u_1 \in U_1$ and

$$dg(u_1) = - \left(\frac{\partial \varphi}{\partial x_2}(u) \right)^{-1} \circ \frac{\partial \varphi}{\partial x_1}(u).$$

It follows that the restriction of J to $(U_1 \times U_2) \cap U$ yields a function G of a single variable, with

$$G(v_1) = J(v_1, g(v_1))$$

for all $v_1 \in U_1$. Now the function G is differentiable at u_1 and it has a local extremum at u_1 on U_1 , so Proposition 40.1 implies that

$$dG(u_1) = 0.$$

By the chain rule,

$$\begin{aligned} dG(u_1) &= \frac{\partial J}{\partial x_1}(u) + \frac{\partial J}{\partial x_2}(u) \circ dg(u_1) \\ &= \frac{\partial J}{\partial x_1}(u) - \frac{\partial J}{\partial x_2}(u) \circ \left(\frac{\partial \varphi}{\partial x_2}(u) \right)^{-1} \circ \frac{\partial \varphi}{\partial x_1}(u). \end{aligned}$$

From $dG(u_1) = 0$, we deduce

$$\frac{\partial J}{\partial x_1}(u) = \frac{\partial J}{\partial x_2}(u) \circ \left(\frac{\partial \varphi}{\partial x_2}(u) \right)^{-1} \circ \frac{\partial \varphi}{\partial x_1}(u),$$

and since we also have

$$\frac{\partial J}{\partial x_2}(u) = \frac{\partial J}{\partial x_2}(u) \circ \left(\frac{\partial \varphi}{\partial x_2}(u) \right)^{-1} \circ \frac{\partial \varphi}{\partial x_2}(u),$$

if we let

$$\Lambda(u) = -\frac{\partial J}{\partial x_2}(u) \circ \left(\frac{\partial \varphi}{\partial x_2}(u) \right)^{-1},$$

then we get

$$\begin{aligned} dJ(u) &= \frac{\partial J}{\partial x_1}(u) + \frac{\partial J}{\partial x_2}(u) \\ &= \frac{\partial J}{\partial x_2}(u) \circ \left(\frac{\partial \varphi}{\partial x_2}(u) \right)^{-1} \circ \left(\frac{\partial \varphi}{\partial x_1}(u) + \frac{\partial \varphi}{\partial x_2}(u) \right) \\ &= -\Lambda(u) \circ d\varphi(u), \end{aligned}$$

which yields $dJ(u) + \Lambda(u) \circ d\varphi(u) = 0$, as claimed. \square

Finally, we prove Theorem 40.2.

Proof of Theorem 40.2. The linear independence of the m linear forms $d\varphi_i(u)$ is equivalent to the fact that the $m \times n$ matrix $A = ((\partial \varphi_i / \partial x_j)(u))$ has rank m . By reordering the columns, we may assume that the first m columns are linearly independent. To conform to the set-up of Theorem 40.4 we define E_1 and E_2 as

$$E_1 = \left\{ \sum_{i=m+1}^n v_i e_i \mid (v_{m+1}, \dots, v_n) \in \mathbb{R}^{n-m} \right\}, \quad E_2 = \left\{ \sum_{i=1}^m v_i e_i \mid (v_1, \dots, v_m) \in \mathbb{R}^m \right\}.$$

If we let $\psi: \Omega \rightarrow \mathbb{R}^m$ be the function defined by

$$\psi(v_{m+1}, \dots, v_n, v_1, \dots, v_m) = (\varphi_1(v), \dots, \varphi_m(v))$$

for all $(v_{m+1}, \dots, v_n, v_1, \dots, v_m) \in \Omega$, with $v = (v_1, \dots, v_n)$, then we see that $\partial \psi / \partial x_2(u)$ is invertible and both $\partial \psi / \partial x_2(u)$ and its inverse are continuous, so that Theorem 40.4 applies, and there is some (continuous) linear form $\Lambda(u) \in \mathcal{L}(\mathbb{R}^m; \mathbb{R})$ such that

$$dJ(u) + \Lambda(u) \circ d\psi(u_{m+1}, \dots, u_n, u_1, \dots, u_m) = 0,$$

namely

$$dJ(u) + \Lambda(u) \circ d\varphi(u) = 0.$$

However, $\Lambda(u)$ is defined by some m -tuple $(\lambda_1(u), \dots, \lambda_m(u)) \in \mathbb{R}^m$, and in view of the definition of φ , the above equation is equivalent to

$$dJ(u) + \lambda_1(u)d\varphi_1(u) + \dots + \lambda_m(u)d\varphi_m(u) = 0.$$

The uniqueness of the $\lambda_i(u)$ is a consequence of the linear independence of the $d\varphi_i(u)$. \square

We now investigate conditions for the existence of extrema involving the second derivative of J .

40.2 Using Second Derivatives to Find Extrema

For the sake of brevity, we consider only the case of local minima; analogous results are obtained for local maxima (replace J by $-J$, since $\max_u J(u) = -\min_u -J(u)$). We begin with a necessary condition for an unconstrained local minimum.

Proposition 40.5. *Let E be a normed vector space and let $J: \Omega \rightarrow \mathbb{R}$ be a function, with Ω some open subset of E . If the function J is differentiable in Ω , if J has a second derivative $D^2J(u)$ at some point $u \in \Omega$, and if J has a local minimum at u , then*

$$D^2J(u)(w, w) \geq 0 \quad \text{for all } w \in E.$$

Proof. Pick any nonzero vector $w \in E$. Since Ω is open, for t small enough, $u + tw \in \Omega$ and $J(u + tw) \geq J(u)$, so there is some open interval $I \subseteq \mathbb{R}$ such that

$$u + tw \in \Omega \quad \text{and} \quad J(u + tw) \geq J(u)$$

for all $t \in I$. Using the Taylor–Young formula and the fact that we must have $dJ(u) = 0$ since J has a local minimum at u , we get

$$0 \leq J(u + tw) - J(u) = \frac{t^2}{2} D^2J(u)(w, w) + t^2 \|w\|^2 \epsilon(tw),$$

with $\lim_{t \rightarrow 0} \epsilon(tw) = 0$, which implies that

$$D^2J(u)(w, w) \geq 0.$$

Since the argument holds for all $w \in E$ (trivially if $w = 0$), the proposition is proven. \square

One should be cautioned that there is no converse to the previous proposition. For example, the function $f: x \mapsto x^3$ has no local minimum at 0, yet $df(0) = 0$ and $D^2f(0)(u, v) = 0$. Similarly, the reader should check that the function $f: \mathbb{R}^2 \rightarrow \mathbb{R}$ given by

$$f(x, y) = x^2 - 3y^3$$

has no local minimum at $(0, 0)$; yet $df(0, 0) = 0$ since $df(x, y) = (2x, -9y^2)$, and for $u = (u_1, u_2)$, $D^2f(0, 0)(u, u) = 2u_1^2 \geq 0$ since

$$D^2f(x, y)(u, u) = (u_1 \ u_2) \begin{pmatrix} 2 & 0 \\ 0 & -18y \end{pmatrix} \begin{pmatrix} u_1 \\ u_2 \end{pmatrix}.$$

See Figure 40.3.

When $E = \mathbb{R}^n$, Proposition 40.5 says that a necessary condition for having a local minimum is that the Hessian $\nabla^2J(u)$ be positive semidefinite (it is always symmetric).

We now give **sufficient** conditions for the existence of a local minimum.

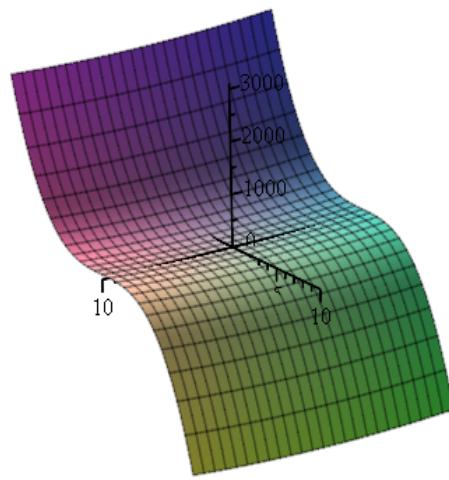

Figure 40.3: The graph of $f(x, y) = x^2 - 3y^3$. Note that $(0, 0)$ is not a local extremum despite the fact that $df(0, 0) = 0$.

Theorem 40.6. Let E be a normed vector space, let $J: \Omega \rightarrow \mathbb{R}$ be a function with Ω some open subset of E , and assume that J is differentiable in Ω and that $dJ(u) = 0$ at some point $u \in \Omega$. The following properties hold:

- (1) If $D^2 J(u)$ exists and if there is some number $\alpha \in \mathbb{R}$ such that $\alpha > 0$ and

$$D^2 J(u)(w, w) \geq \alpha \|w\|^2 \quad \text{for all } w \in E,$$

then J has a strict local minimum at u .

- (2) If $D^2 J(v)$ exists for all $v \in \Omega$ and if there is a ball $B \subseteq \Omega$ centered at u such that

$$D^2 J(v)(w, w) \geq 0 \quad \text{for all } v \in B \text{ and all } w \in E,$$

then J has a local minimum at u .

Proof. (1) Using the formula of Taylor–Young, for every vector w small enough, we can write

$$\begin{aligned} J(u + w) - J(u) &= \frac{1}{2} D^2 J(u)(w, w) + \|w\|^2 \epsilon(w) \\ &\geq \left(\frac{1}{2} \alpha + \epsilon(w) \right) \|w\|^2 \end{aligned}$$

with $\lim_{w \rightarrow 0} \epsilon(w) = 0$. Consequently if we pick $r > 0$ small enough that $|\epsilon(w)| < \alpha/2$ for all w with $\|w\| < r$, then $J(u + w) > J(u)$ for all $u + w \in B$, where B is the open ball of center u and radius r . This proves that J has a local strict minimum at u .

(2) The formula of Taylor–Maclaurin shows that for all $u + w \in B$, we have

$$J(u + w) = J(u) + \frac{1}{2}D^2J(v)(w, w) \geq J(u),$$

for some $v \in (u, u + w)$ (recall that $(u, u + w) = \{(1 - \lambda)(u + w) + \lambda(u + w) \mid 0 < \lambda < 1\}$). \square

There are no converses of the two assertions of Theorem 40.6. However, there is a condition on $D^2J(u)$ that implies the condition of Part (1). Since this condition is easier to state when $E = \mathbb{R}^n$, we begin with this case.

Recall that a $n \times n$ symmetric matrix A is *positive definite* if $x^\top Ax > 0$ for all $x \in \mathbb{R}^n - \{0\}$. In particular, A must be invertible.

Proposition 40.7. *For any symmetric matrix A , if A is positive definite, then there is some $\alpha > 0$ such that*

$$x^\top Ax \geq \alpha \|x\|^2 \quad \text{for all } x \in \mathbb{R}^n.$$

Proof. Pick any norm in \mathbb{R}^n (recall that all norms on \mathbb{R}^n are equivalent). Since the unit sphere $S^{n-1} = \{x \in \mathbb{R}^n \mid \|x\| = 1\}$ is compact and since the function $f(x) = x^\top Ax$ is never zero on S^{n-1} , the function f has a minimum $\alpha > 0$ on S^{n-1} . Using the usual trick that $x = \|x\|(x/\|x\|)$ for every nonzero vector $x \in \mathbb{R}^n$ and the fact that the inequality of the proposition is trivial for $x = 0$, from

$$x^\top Ax \geq \alpha \quad \text{for all } x \text{ with } \|x\| = 1,$$

we get

$$x^\top Ax \geq \alpha \|x\|^2 \quad \text{for all } x \in \mathbb{R}^n,$$

as claimed. \square

We can combine Theorem 40.6 and Proposition 40.7 to obtain a **useful sufficient condition for the existence of a strict local minimum**. First let us introduce some terminology.

Definition 40.6. Given a function $J: \Omega \rightarrow \mathbb{R}$ as before, say that a point $u \in \Omega$ is a *nondegenerate critical point* if $dJ(u) = 0$ and if the Hessian matrix $\nabla^2J(u)$ is invertible.

Proposition 40.8. *Let $J: \Omega \rightarrow \mathbb{R}$ be a function defined on some open subset $\Omega \subseteq \mathbb{R}^n$. If J is differentiable in Ω and if some point $u \in \Omega$ is a nondegenerate critical point such that $\nabla^2J(u)$ is positive definite, then J has a strict local minimum at u .*

Remark: It is possible to generalize Proposition 40.8 to infinite-dimensional spaces by finding a suitable generalization of the notion of a nondegenerate critical point. Firstly, we assume that E is a Banach space (a complete normed vector space). Then we define the dual E' of E as the set of continuous linear forms on E , so that $E' = \mathcal{L}(E; \mathbb{R})$. Following Lang, we use the notation E' for the space of continuous linear forms to avoid confusion

with the space $E^* = \text{Hom}(E, \mathbb{R})$ of all linear maps from E to \mathbb{R} . A continuous bilinear map $\varphi: E \times E \rightarrow \mathbb{R}$ in $\mathcal{L}_2(E, E; \mathbb{R})$ yields a map Φ from E to E' given by

$$\Phi(u) = \varphi_u,$$

where $\varphi_u \in E'$ is the linear form defined by

$$\varphi_u(v) = \varphi(u, v).$$

It is easy to check that φ_u is continuous and that the map Φ is continuous. Then we say that φ is *nondegenerate* iff $\Phi: E \rightarrow E'$ is an isomorphism of Banach spaces, which means that Φ is invertible and that both Φ and Φ^{-1} are continuous linear maps. Given a function $J: \Omega \rightarrow \mathbb{R}$ differentiable on Ω as before (where Ω is an open subset of E), if $D^2J(u)$ exists for some $u \in \Omega$, we say that u is a *nondegenerate critical point* if $dJ(u) = 0$ and if $D^2J(u)$ is nondegenerate. Of course, $D^2J(u)$ is positive definite if $D^2J(u)(w, w) > 0$ for all $w \in E - \{0\}$.

Using the above definition, Proposition 40.7 can be generalized to a nondegenerate positive definite bilinear form (on a Banach space) and Theorem 40.8 can also be generalized to the situation where $J: \Omega \rightarrow \mathbb{R}$ is defined on an open subset of a Banach space. For details and proofs, see Cartan [34] (Part I Chapter 8) and Avez [9] (Chapter 8 and Chapter 10).

In the next section we make use of convexity; both on the domain Ω and on the function J itself.

40.3 Using Convexity to Find Extrema

We begin by reviewing the definition of a convex set and of a convex function.

Definition 40.7. Given any real vector space E , we say that a subset C of E is *convex* if either $C = \emptyset$ or if for every pair of points $u, v \in C$, the line segment connecting u and v is contained in C , i.e.,

$$(1 - \lambda)u + \lambda v \in C \quad \text{for all } \lambda \in \mathbb{R} \text{ such that } 0 \leq \lambda \leq 1.$$

Given any two points $u, v \in E$, the *line segment* $[u, v]$ is the set

$$[u, v] = \{(1 - \lambda)u + \lambda v \in E \mid \lambda \in \mathbb{R}, 0 \leq \lambda \leq 1\}.$$

Clearly, a nonempty set C is convex iff $[u, v] \subseteq C$ whenever $u, v \in C$. See Figure 40.4 for an example of a convex set.

Definition 40.8. If C is a nonempty convex subset of E , a function $f: C \rightarrow \mathbb{R}$ is *convex* (on C) if for every pair of points $u, v \in C$,

$$f((1 - \lambda)u + \lambda v) \leq (1 - \lambda)f(u) + \lambda f(v) \quad \text{for all } \lambda \in \mathbb{R} \text{ such that } 0 \leq \lambda \leq 1;$$

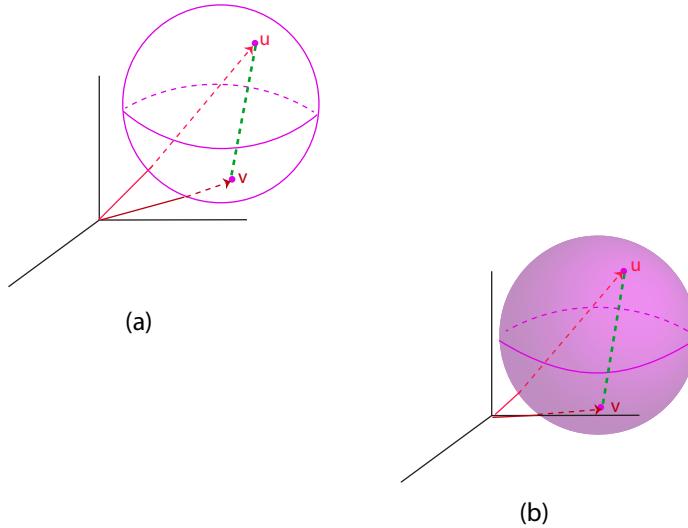

Figure 40.4: Figure (a) shows that a sphere is not convex in \mathbb{R}^3 since the dashed green line does not lie on its surface. Figure (b) shows that a solid ball is convex in \mathbb{R}^3 .

the function f is *strictly convex* (on C) if for every pair of distinct points $u, v \in C$ ($u \neq v$),

$$f((1 - \lambda)u + \lambda v) < (1 - \lambda)f(u) + \lambda f(v) \quad \text{for all } \lambda \in \mathbb{R} \text{ such that } 0 < \lambda < 1;$$

see Figure 40.5. The *epigraph*¹ $\text{epi}(f)$ of a function $f: A \rightarrow \mathbb{R}$ defined on some subset A of \mathbb{R}^n is the subset of \mathbb{R}^{n+1} defined as

$$\text{epi}(f) = \{(x, y) \in \mathbb{R}^{n+1} \mid f(x) \leq y, x \in A\}.$$

A function $f: C \rightarrow \mathbb{R}$ defined on a convex subset C is *concave* (resp. *strictly concave*) if $(-f)$ is convex (resp. strictly convex).

It is obvious that a function f is convex iff its epigraph $\text{epi}(f)$ is a convex subset of \mathbb{R}^{n+1} .

Example 40.4. Here are some common examples of convex sets.

- Subspaces $V \subseteq E$ of a vector space E are convex.
- *Affine subspaces*, that is, sets of the form $u + V$, where V is a subspace of E and $u \in E$, are convex.
- Balls (open or closed) are convex. Given any linear form $\varphi: E \rightarrow \mathbb{R}$, for any scalar $c \in \mathbb{R}$, the *closed half-spaces*

$$H_{\varphi,c}^+ = \{u \in E \mid \varphi(u) \geq c\}, \quad H_{\varphi,c}^- = \{u \in E \mid \varphi(u) \leq c\},$$

are convex.

¹ “Epi” means above.

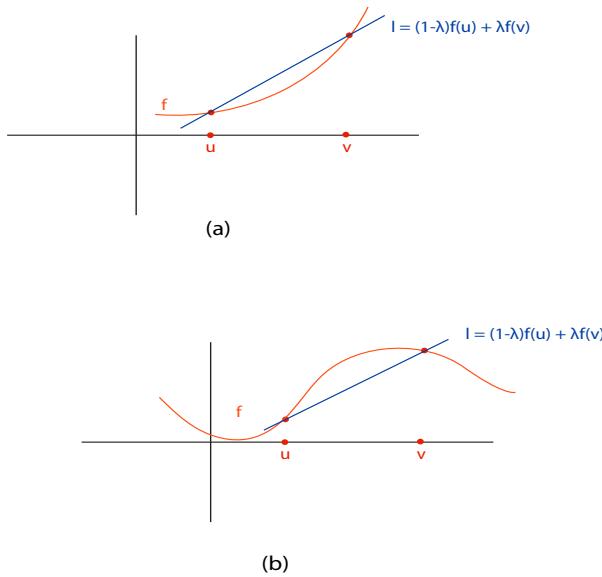

Figure 40.5: Figures (a) and (b) are the graphs of real valued functions. Figure (a) is the graph of convex function since the blue line lies above the graph of f . Figure (b) shows the graph of a function which is not convex.

- Any intersection of half-spaces is convex.
- More generally, any intersection of convex sets is convex.

Example 40.5. Here are some common examples of convex and concave functions.

- Linear forms are convex functions (but not strictly convex).
- Any norm $\| \cdot \| : E \rightarrow \mathbb{R}_+$ is a convex function.
- The max function,

$$\max(x_1, \dots, x_n) = \max\{x_1, \dots, x_n\}$$

is convex on \mathbb{R}^n .

- The exponential $x \mapsto e^{cx}$ is strictly convex for any $c \neq 0$ ($c \in \mathbb{R}$).
- The logarithm function is concave on $\mathbb{R}_+ - \{0\}$.
- The *log-determinant function* $\log \det$ is concave on the set of symmetric positive definite matrices. This function plays an important role in convex optimization.

An excellent exposition of convexity and its applications to optimization can be found in Boyd [29].

Here is a necessary condition for a function to have a local minimum with respect to a convex subset U .

Theorem 40.9. (*Necessary condition for a local minimum on a convex subset*) Let $J: \Omega \rightarrow \mathbb{R}$ be a function defined on some open subset Ω of a normed vector space E and let $U \subseteq \Omega$ be a nonempty convex subset. Given any $u \in U$, if $dJ(u)$ exists and if J has a local minimum in u with respect to U , then

$$dJ(u)(v - u) \geq 0 \quad \text{for all } v \in U.$$

Proof. Let $v = u + w$ be an arbitrary point in U . Since U is convex, we have $u + tw \in U$ for all t such that $0 \leq t \leq 1$. Since $dJ(u)$ exists, we can write

$$J(u + tw) - J(u) = dJ(u)(tw) + \|tw\| \epsilon(tw)$$

with $\lim_{t \rightarrow 0} \epsilon(tw) = 0$. However, because $0 \leq t$,

$$J(u + tw) - J(u) = t(dJ(u)(w) + \|w\| \epsilon(tw))$$

and since u is a local minimum with respect to U , we have $J(u + tw) - J(u) \geq 0$, so we get

$$t(dJ(u)(w) + \|w\| \epsilon(tw)) \geq 0.$$

The above implies that $dJ(u)(w) \geq 0$, because otherwise we could pick $t > 0$ small enough so that

$$dJ(u)(w) + \|w\| \epsilon(tw) < 0,$$

a contradiction. Since the argument holds for all $v = u + w \in U$, the theorem is proven. \square

Observe that the convexity of U is a substitute for the use of Lagrange multipliers, but we now have to deal with an *inequality* instead of an equality.

In the special case where U is a subspace of E we have the following result.

Corollary 40.10. *With the same assumptions as in Theorem 40.9, if U is a subspace of E , if $dJ(u)$ exists and if J has a local minimum in u with respect to U , then*

$$dJ(u)(w) = 0 \quad \text{for all } w \in U.$$

Proof. In this case since $u \in U$ we have $2u \in U$, and for any $u + w \in U$, we must have $2u - (u + w) = u - w \in U$. The previous theorem implies that $dJ(u)(w) \geq 0$ and $dJ(u)(-w) \geq 0$, that is, $dJ(u)(w) \leq 0$, so $dJ(u) = 0$. Since the argument holds for $w \in U$ (because U is a subspace, if $u, w \in U$, then $u + w \in U$), we conclude that

$$dJ(u)(w) = 0 \quad \text{for all } w \in U. \quad \square$$

We will now characterize convex functions when they have a first derivative or a second derivative.

Proposition 40.11. (*Convexity and first derivative*) Let $f: \Omega \rightarrow \mathbb{R}$ be a function differentiable on some open subset Ω of a normed vector space E and let $U \subseteq \Omega$ be a nonempty convex subset.

(1) The function f is convex on U iff

$$f(v) \geq f(u) + df(u)(v - u) \quad \text{for all } u, v \in U.$$

(2) The function f is strictly convex on U iff

$$f(v) > f(u) + df(u)(v - u) \quad \text{for all } u, v \in U \text{ with } u \neq v.$$

See Figure 40.6.

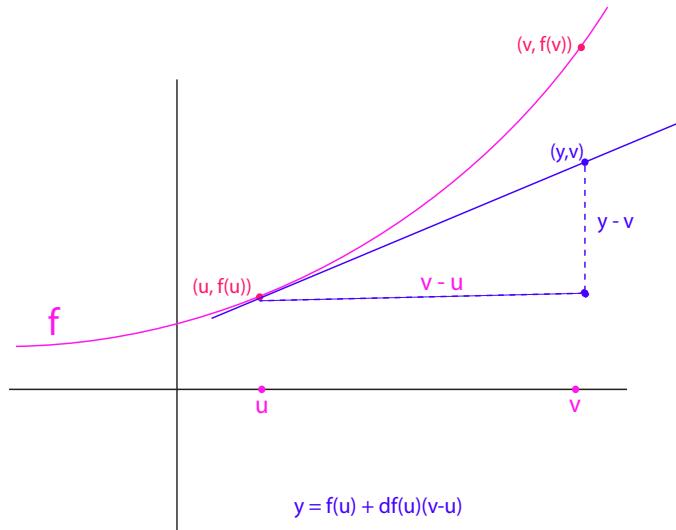

Figure 40.6: An illustration of a convex valued function f . Since f is convex it always lies above its tangent line.

Proof. Let $u, v \in U$ be any two distinct points and pick $\lambda \in \mathbb{R}$ with $0 < \lambda < 1$. If the function f is convex, then

$$f((1 - \lambda)u + \lambda v) \leq (1 - \lambda)f(u) + \lambda f(v),$$

which yields

$$\frac{f((1 - \lambda)u + \lambda v) - f(u)}{\lambda} \leq f(v) - f(u).$$

It follows that

$$df(u)(v - u) = \lim_{\lambda \rightarrow 0} \frac{f((1 - \lambda)u + \lambda v) - f(u)}{\lambda} \leq f(v) - f(u).$$

If f is strictly convex, the above reasoning does not work, because a strict inequality is not necessarily preserved by “passing to the limit.” We have recourse to the following trick: for any ω such that $0 < \omega < 1$, observe that

$$(1 - \lambda)u + \lambda v = u + \lambda(v - u) = \frac{\omega - \lambda}{\omega}u + \frac{\lambda}{\omega}(u + \omega(v - u)).$$

If we assume that $0 < \lambda \leq \omega$, the convexity of f yields

$$f(u + \lambda(v - u)) = f\left(\left(1 - \frac{\lambda}{\omega}\right)u + \frac{\lambda}{\omega}(u + \omega(v - u))\right) \leq \frac{\omega - \lambda}{\omega}f(u) + \frac{\lambda}{\omega}f(u + \omega(v - u)).$$

If we subtract $f(u)$ to both sides, we get

$$\frac{f(u + \lambda(v - u)) - f(u)}{\lambda} \leq \frac{f(u + \omega(v - u)) - f(u)}{\omega}.$$

Now since $0 < \omega < 1$ and f is strictly convex,

$$f(u + \omega(v - u)) = f((1 - \omega)u + \omega v) < (1 - \omega)f(u) + \omega f(v),$$

which implies that

$$\frac{f(u + \omega(v - u)) - f(u)}{\omega} < f(v) - f(u),$$

and thus we get

$$\frac{f(u + \lambda(v - u)) - f(u)}{\lambda} \leq \frac{f(u + \omega(v - u)) - f(u)}{\omega} < f(v) - f(u).$$

If we let λ go to 0, by passing to the limit we get

$$df(u)(v - u) \leq \frac{f(u + \omega(v - u)) - f(u)}{\omega} < f(v) - f(u),$$

which yields the desired strict inequality.

Let us now consider the converse of (1); that is, assume that

$$f(v) \geq f(u) + df(u)(v - u) \quad \text{for all } u, v \in U.$$

For any two distinct points $u, v \in U$ and for any λ with $0 < \lambda < 1$, we get

$$\begin{aligned} f(v) &\geq f(v + \lambda(u - v)) - \lambda df(v + \lambda(u - v))(u - v) \\ f(u) &\geq f(v + \lambda(u - v)) + (1 - \lambda)df(v + \lambda(u - v))(u - v), \end{aligned}$$

and if we multiply the first inequality by $1 - \lambda$ and the second inequality by λ and then add up the resulting inequalities, we get

$$(1 - \lambda)f(v) + \lambda f(u) \geq f(v + \lambda(u - v)) = f((1 - \lambda)v + \lambda u),$$

which proves that f is convex.

The proof of the converse of (2) is similar, except that the inequalities are replaced by strict inequalities. \square

We now establish a convexity criterion using the second derivative of f . This criterion is often easier to check than the previous one.

Proposition 40.12. (*Convexity and second derivative*) *Let $f: \Omega \rightarrow \mathbb{R}$ be a function twice differentiable on some open subset Ω of a normed vector space E and let $U \subseteq \Omega$ be a nonempty convex subset.*

(1) *The function f is convex on U iff*

$$D^2f(u)(v-u, v-u) \geq 0 \quad \text{for all } u, v \in U.$$

(2) *If*

$$D^2f(u)(v-u, v-u) > 0 \quad \text{for all } u, v \in U \text{ with } u \neq v,$$

then f is strictly convex.

Proof. First assume that the inequality in Condition (1) is satisfied. For any two distinct points $u, v \in U$, the formula of Taylor–Maclaurin yields

$$\begin{aligned} f(v) - f(u) - df(u)(v-u) &= \frac{1}{2} D^2f(w)(v-u, v-u) \\ &= \frac{\rho^2}{2} D^2f(w)(v-w, v-w), \end{aligned}$$

for some $w = (1-\lambda)u + \lambda v = u + \lambda(v-u)$ with $0 < \lambda < 1$, and with $\rho = 1/(1-\lambda) > 0$, so that $v-u = \rho(v-w)$. Since $D^2f(w)(v-w, v-w) \geq 0$ for all $u, w \in U$, we conclude by applying Proposition 40.11(1).

Similarly, if (2) holds, the above reasoning and Proposition 40.11(2) imply that f is strictly convex.

To prove the necessary condition in (1), define $g: \Omega \rightarrow \mathbb{R}$ by

$$g(v) = f(v) - df(u)(v),$$

where $u \in U$ is any point considered fixed. If f is convex, since

$$g(v) - g(u) = f(v) - f(u) - df(u)(v-u),$$

Proposition 40.11 implies that $f(v) - f(u) - df(u)(v-u) \geq 0$, which implies that g has a local minimum at u with respect to all $v \in U$. Therefore, we have $dg(u) = 0$. Observe that g is twice differentiable in Ω and $D^2g(u) = D^2f(u)$, so the formula of Taylor–Young yields for every $v = u + w \in U$ and all t with $0 \leq t \leq 1$,

$$\begin{aligned} 0 \leq g(u+tw) - g(u) &= \frac{t^2}{2} D^2f(u)(tw, tw) + \|tw\|^2 \epsilon(tw) \\ &= \frac{t^2}{2} (D^2f(u)(w, w) + 2\|w\|^2 \epsilon(wt)), \end{aligned}$$

with $\lim_{t \rightarrow 0} \epsilon(wt) = 0$, and for t small enough, we must have $D^2f(u)(w, w) \geq 0$, as claimed. \square

The converse of Proposition 40.12 (2) is false as we see by considering the strictly convex function f given by $f(x) = x^4$ and its second derivative at $x = 0$.

Example 40.6. On the other hand, if f is a quadratic function of the form

$$f(u) = \frac{1}{2}u^\top Au - u^\top b$$

where A is a symmetric matrix, we know that

$$df(u)(v) = v^\top(Au - b),$$

so

$$\begin{aligned} f(v) - f(u) - df(u)(v - u) &= \frac{1}{2}v^\top Av - v^\top b - \frac{1}{2}u^\top Au + u^\top b - (v - u)^\top(Au - b) \\ &= \frac{1}{2}v^\top Av - \frac{1}{2}u^\top Au - (v - u)^\top Au \\ &= \frac{1}{2}v^\top Av + \frac{1}{2}u^\top Au - v^\top Au \\ &= \frac{1}{2}(v - u)^\top A(v - u). \end{aligned}$$

Therefore, Proposition 40.11 implies that if A is positive semidefinite, then f is convex and if A is positive definite, then f is strictly convex. The converse follows by Proposition 40.12.

We conclude this section by applying our previous theorems to convex functions defined on convex subsets. In this case local minima (resp. local maxima) are global minima (resp. global maxima). The next definition is the special case of Definition 40.1 in which $W = E$ but it does not hurt to state it explicitly.

Definition 40.9. Let $f: E \rightarrow \mathbb{R}$ be any function defined on some normed vector space (or more generally, any set). For any $u \in E$, we say that f has a *minimum* in u (resp. *maximum* in u) if

$$f(u) \leq f(v) \text{ (resp. } f(u) \geq f(v)) \quad \text{for all } v \in E.$$

We say that f has a *strict minimum* in u (resp. *strict maximum* in u) if

$$f(u) < f(v) \text{ (resp. } f(u) > f(v)) \quad \text{for all } v \in E - \{u\}.$$

If $U \subseteq E$ is a subset of E and $u \in U$, we say that f has a *minimum* in u (resp. *strict minimum* in u) *with respect to* U if

$$f(u) \leq f(v) \quad \text{for all } v \in U \quad (\text{resp. } f(u) < f(v) \quad \text{for all } v \in U - \{u\}),$$

and similarly for a *maximum* in u (resp. *strict maximum* in u) *with respect to* U with \leq changed to \geq and $<$ to $>$.

Sometimes, we say *global* maximum (or minimum) to stress that a maximum (or a minimum) is not simply a local maximum (or minimum).

Theorem 40.13. *Given any normed vector space E , let U be any nonempty convex subset of E .*

- (1) *For any convex function $J: U \rightarrow \mathbb{R}$, for any $u \in U$, if J has a local minimum at u in U , then J has a (global) minimum at u in U .*
- (2) *Any strict convex function $J: U \rightarrow \mathbb{R}$ has at most one minimum (in U), and if it does, then it is a strict minimum (in U).*
- (3) *Let $J: \Omega \rightarrow \mathbb{R}$ be any function defined on some open subset Ω of E with $U \subseteq \Omega$ and assume that J is convex on U . For any point $u \in U$, if $dJ(u)$ exists, then J has a minimum in u with respect to U iff*

$$dJ(u)(v - u) \geq 0 \quad \text{for all } v \in U.$$

- (4) *If the convex subset U in (3) is open, then the above condition is equivalent to*

$$dJ(u) = 0.$$

Proof. (1) Let $v = u + w$ be any arbitrary point in U . Since J is convex, for all t with $0 \leq t \leq 1$, we have

$$J(u + tw) = J(u + t(v - u)) = J((1 - t)u + tv) \leq (1 - t)J(u) + tJ(v),$$

which yields

$$J(u + tw) - J(u) \leq t(J(v) - J(u)).$$

Because J has a local minimum at u , there is some t_0 with $0 < t_0 < 1$ such that

$$0 \leq J(u + t_0w) - J(u) \leq t_0(J(v) - J(u)),$$

which implies that $J(v) - J(u) \geq 0$.

(2) If J is strictly convex, the above reasoning with $w \neq 0$ shows that there is some t_0 with $0 < t_0 < 1$ such that

$$0 \leq J(u + t_0w) - J(u) < t_0(J(v) - J(u)),$$

which shows that u is a strict global minimum (in U), and thus that it is unique.

(3) We already know from Theorem 40.9 that the condition $dJ(u)(v - u) \geq 0$ for all $v \in U$ is necessary (even if J is not convex). Conversely, because J is convex, careful inspection of the proof of Part (1) of Proposition 40.11 shows that only the fact that $dJ(u)$ exists is needed to prove that

$$J(v) - J(u) \geq dJ(u)(v - u) \quad \text{for all } v \in U,$$

and if

$$dJ(u)(v - u) \geq 0 \quad \text{for all } v \in U,$$

then

$$J(v) - J(u) \geq 0 \quad \text{for all } v \in U,$$

as claimed.

(4) If U is open, then for every $u \in U$ we can find an open ball B centered at u of radius ϵ small enough so that $B \subseteq U$. Then for any $w \neq 0$ such that $\|w\| < \epsilon$, we have both $v = u + w \in B$ and $v' = u - w \in B$, so Condition (3) implies that

$$dJ(u)(w) \geq 0 \quad \text{and} \quad dJ(u)(-w) \geq 0,$$

which yields

$$dJ(u)(w) = 0.$$

Since the above holds for all $w \neq 0$ such that $\|w\| < \epsilon$ and since $dJ(u)$ is linear, we leave it to the reader to fill in the details of the proof that $dJ(u) = 0$. \square

Example 40.7. Theorem 40.13 can be used to rederive the fact that the least squares solutions of a linear system $Ax = b$ (where A is an $m \times n$ matrix) are given by the normal equation

$$A^\top Ax = A^\top b.$$

For this, we consider the quadratic function

$$J(v) = \frac{1}{2} \|Av - b\|_2^2 - \frac{1}{2} \|b\|_2^2,$$

and our least squares problem is equivalent to finding the minima of J on \mathbb{R}^n . A computation reveals that

$$\begin{aligned} J(v) &= \frac{1}{2} \|Av - b\|_2^2 - \frac{1}{2} \|b\|_2^2 \\ &= \frac{1}{2}(Av - b)^\top(Av - b) - \frac{1}{2}b^\top b \\ &= \frac{1}{2}(v^\top A^\top - b^\top)(Av - b) - \frac{1}{2}b^\top b \\ &= \frac{1}{2}v^\top A^\top Av - v^\top A^\top b, \end{aligned}$$

and so

$$dJ(u) = A^\top Au - A^\top b.$$

Since $A^\top A$ is positive semidefinite, the function J is convex, and Theorem 40.13(4) implies that the minima of J are the solutions of the equation

$$A^\top Au - A^\top b = 0.$$

The considerations in this chapter reveal the need to find methods for finding the zeros of the derivative map

$$dJ: \Omega \rightarrow E',$$

where Ω is some open subset of a normed vector space E and E' is the space of all continuous linear forms on E (a subspace of E^*). Generalizations of *Newton's method* yield such methods and they are the object of the next chapter.

40.4 Summary

The main concepts and results of this chapter are listed below:

- Local minimum, local maximum, local extremum, strict local minimum, strict local maximum.
- Necessary condition for a local extremum involving the derivative; critical point.
- Local minimum with respect to a subset U , local maximum with respect to a subset U , local extremum with respect to a subset U .
- Constrained local extremum.
- Necessary condition for a constrained extremum.
- Necessary condition for a constrained extremum in terms of Lagrange multipliers.
- Lagrangian.
- Critical points of a Lagrangian.
- Necessary condition of an unconstrained local minimum involving the second-order derivative.
- Sufficient condition for a local minimum involving the second-order derivative.
- A sufficient condition involving nondegenerate critical points.
- Convex sets, convex functions, concave functions, strictly convex functions, strictly concave functions.
- Necessary condition for a local minimum on a convex set involving the derivative.
- Convexity of a function involving a condition on its first derivative.
- Convexity of a function involving a condition on its second derivative.
- Minima of convex functions on convex sets.

40.5 Problems

Problem 40.1. Find the extrema of the function $J(v_1, v_2) = v_2^2$ on the subset U given by

$$U = \{(v_1, v_2) \in \mathbb{R}^2 \mid v_1^2 + v_2^2 - 1 = 0\}.$$

Problem 40.2. Find the extrema of the function $J(v_1, v_2) = v_1 + (v_2 - 1)^2$ on the subset U given by

$$U = \{(v_1, v_2) \in \mathbb{R}^2 \mid v_1^2 = 0\}.$$

Problem 40.3. Let A be an $n \times n$ real symmetric matrix, B an $n \times n$ symmetric positive definite matrix, and let $b \in \mathbb{R}^n$.

- (1) Prove that a necessary condition for the function J given by

$$J(v) = \frac{1}{2}v^\top Av - b^\top v$$

to have an extremum at $u \in U$, with U defined by

$$U = \{v \in \mathbb{R}^n \mid v^\top Bv = 1\},$$

is that there is some $\lambda \in \mathbb{R}$ such that

$$Au - b = \lambda Bu.$$

(2) Prove that there is a symmetric positive definite matrix S such that $B = S^2$. Prove that if $b = 0$, then λ is an eigenvalue of the symmetric matrix $S^{-1}AS^{-1}$.

- (3) Prove that for all $(u, \lambda) \in U \times \mathbb{R}$, if $Au - b = \lambda Bu$, then

$$J(v) - J(u) = \frac{1}{2}(v - u)^\top (A - \lambda B)(v - u)$$

for all $v \in U$. Deduce that without additional assumptions, it is not possible to conclude that u is an extremum of J on U .

Problem 40.4. Let E be a normed vector space, and let U be a subset of E such that for all $u, v \in U$, we have $(1/2)(u + v) \in U$.

- (1) Prove that if U is closed, then U is convex.

Hint. Every real $\theta \in (0, 1)$ can be written as

$$\theta = \sum_{n \geq 1} \alpha_n 2^{-n},$$

with $\alpha_n \in \{0, 1\}$.

- (2) Does the result in (1) hold if U is not closed?

Problem 40.5. Prove that the function f with domain $\text{dom}(f) = \mathbb{R} - \{0\}$ given by $f(x) = 1/x^2$ has the property that $f''(x) > 0$ for all $x \in \text{dom}(f)$, but it is not convex. Why isn't Proposition 40.12 applicable?

Problem 40.6. (1) Prove that the function $x \mapsto e^{ax}$ (on \mathbb{R}) is convex for any $a \in \mathbb{R}$.

(2) Prove that the function $x \mapsto x^a$ is convex on $\{x \in \mathbb{R} \mid x > 0\}$, for all $a \in \mathbb{R}$ such that $a \leq 0$ or $a \geq 1$.

Problem 40.7. (1) Prove that the function $x \mapsto |x|^p$ is convex on \mathbb{R} for all $p \geq 1$.

(2) Prove that the function $x \mapsto \log x$ is concave on $\{x \in \mathbb{R} \mid x > 0\}$.

(3) Prove that the function $x \mapsto x \log x$ is convex on $\{x \in \mathbb{R} \mid x > 0\}$.

Problem 40.8. (1) Prove that the function f given by $f(x_1, \dots, x_n) = \max\{x_1, \dots, x_n\}$ is convex on \mathbb{R}^n .

(2) Prove that the function g given by $g(x_1, \dots, x_n) = \log(e^{x_1} + \dots + e^{x_n})$ is convex on \mathbb{R}^n .

Prove that

$$\max\{x_1, \dots, x_n\} \leq g(x_1, \dots, x_n) \leq \max\{x_1, \dots, x_n\} + \log n.$$

Problem 40.9. In Problem 39.6, it was shown that

$$\begin{aligned} df_A(X) &= \text{tr}(A^{-1}X) \\ D^2f(A)(X_1, X_2) &= -\text{tr}(A^{-1}X_1 A^{-1}X_2), \end{aligned}$$

for all $n \times n$ real matrices X, X_1, X_2 , where f is the function defined on $\mathbf{GL}^+(n, \mathbb{R})$ (the $n \times n$ real invertible matrices of positive determinants), given by

$$f(A) = \log \det(A).$$

Assume that A is symmetric positive definite and that X is symmetric.

(1) Prove that the eigenvalues of $A^{-1}X$ are real (even though $A^{-1}X$ may **not** be symmetric).

Hint. Since A is symmetric positive definite, then so is A^{-1} , so we can write $A^{-1} = S^2$ for some symmetric positive definite matrix S , and then

$$A^{-1}X = S^2X = S(SXS)S^{-1}.$$

(2) Prove that the eigenvalues of $(A^{-1}X)^2$ are nonnegative. Deduce that

$$D^2f(A)(X, X) = -\text{tr}((A^{-1}X)^2) < 0$$

for all nonzero symmetric matrices X and SPD matrices A . Conclude that the function $X \mapsto \log \det X$ is strictly concave on the set of symmetric positive definite matrices.

Chapter 41

Newton's Method and Its Generalizations

In Chapter 40 we investigated the problem of determining when a function $J: \Omega \rightarrow \mathbb{R}$ defined on some open subset Ω of a normed vector space E has a local extremum. Proposition 40.1 gives a necessary condition when J is differentiable: if J has a local extremum at $u \in \Omega$, then we must have

$$J'(u) = 0.$$

Thus we are led to the problem of finding the zeros of the derivative

$$J': \Omega \rightarrow E',$$

where $E' = \mathcal{L}(E; \mathbb{R})$ is the set of linear continuous functions from E to \mathbb{R} ; that is, the *dual* of E , as defined in the remark after Proposition 40.8.

This leads us to consider the problem in a more general form, namely, given a function $f: \Omega \rightarrow Y$ from an open subset Ω of a normed vector space X to a normed vector space Y , find

- (i) Sufficient conditions which guarantee the *existence of a zero* of the function f ; that is, an element $a \in \Omega$ such that $f(a) = 0$.
- (ii) An *algorithm* for approximating such an a , that is, a sequence (x_k) of points of Ω whose limit is a .

In this chapter we discuss Newton's method and some of its generalizations to give (partial) answers to Problems (i) and (ii).

41.1 Newton's Method for Real Functions of a Real Argument

When $X = Y = \mathbb{R}$, we can use *Newton's method* to find a zero of a function $f: \Omega \rightarrow \mathbb{R}$. We pick some initial element $x_0 \in \mathbb{R}$ "close enough" to a zero a of f , and we define the sequence

(x_k) by

$$x_{k+1} = x_k - \frac{f(x_k)}{f'(x_k)},$$

for all $k \geq 0$, provided that $f'(x_k) \neq 0$. The idea is to define x_{k+1} as the intersection of the x -axis with the tangent line to the graph of the function $x \mapsto f(x)$ at the point $(x_k, f(x_k))$. Indeed, the equation of this tangent line is

$$y - f(x_k) = f'(x_k)(x - x_k),$$

and its intersection with the x -axis is obtained for $y = 0$, which yields

$$x = x_k - \frac{f(x_k)}{f'(x_k)},$$

as claimed. See Figure 41.1.

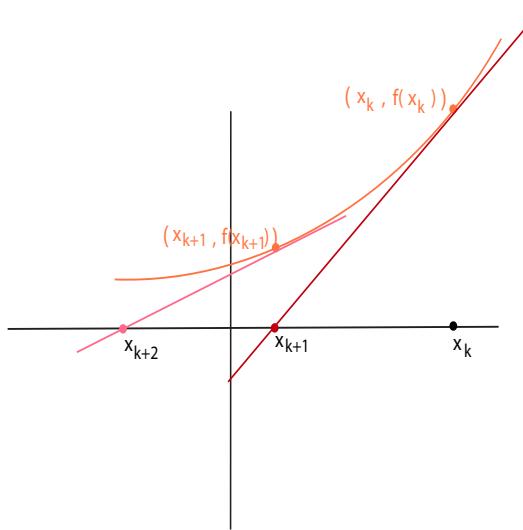

Figure 41.1: The construction of two stages in Newton's method.

Example 41.1. If $\alpha > 0$ and $f(x) = x^2 - \alpha$, Newton's method yields the sequence

$$x_{k+1} = \frac{1}{2} \left(x_k + \frac{\alpha}{x_k} \right)$$

to compute the square root $\sqrt{\alpha}$ of α . It can be shown that the method converges to $\sqrt{\alpha}$ for any $x_0 > 0$; see Problem 41.1. Actually, the method also converges when $x_0 < 0$! Find out what is the limit.

The case of a real function suggests the following method for finding the zeros of a function $f: \Omega \rightarrow Y$, with $\Omega \subseteq X$: given a starting point $x_0 \in \Omega$, the sequence (x_k) is defined by

$$x_{k+1} = x_k - (f'(x_k))^{-1}(f(x_k)) \quad (*)$$

for all $k \geq 0$.

For the above to make sense, it must be ensured that

- (1) All the points x_k remain within Ω .
- (2) The function f is differentiable within Ω .
- (3) The derivative $f'(x)$ is a bijection from X to Y for all $x \in \Omega$.

These are rather demanding conditions but there are sufficient conditions that guarantee that they are met. Another practical issue is that it may be very costly to compute $(f'(x_k))^{-1}$ at every iteration step. In the next section we investigate generalizations of Newton's method which address the issues that we just discussed.

41.2 Generalizations of Newton's Method

Suppose that $f: \Omega \rightarrow \mathbb{R}^n$ is given by n functions $f_i: \Omega \rightarrow \mathbb{R}$, where $\Omega \subseteq \mathbb{R}^n$. In this case, finding a zero a of f is equivalent to solving the system

$$\begin{aligned} f_1(a_1, \dots, a_n) &= 0 \\ f_2(a_1, \dots, a_n) &= 0 \\ &\vdots \\ f_n(a_1, \dots, a_n) &= 0. \end{aligned}$$

In the standard Newton method, the iteration step is given by $(*)$, namely

$$x_{k+1} = x_k - (f'(x_k))^{-1}(f(x_k)),$$

and if we define Δx_k as $\Delta x_k = x_{k+1} - x_k$, we see that $\Delta x_k = -(f'(x_k))^{-1}(f(x_k))$, so Δx_k is obtained by solving the equation

$$f'(x_k)\Delta x_k = -f(x_k),$$

and then we set $x_{k+1} = x_k + \Delta x_k$.

The generalization is as follows.

Variant 1. A single iteration of Newton's method consists in solving the linear system

$$(J(f)(x_k))\Delta x_k = -f(x_k),$$

and then setting

$$x_{k+1} = x_k + \Delta x_k,$$

where $J(f)(x_k) = \left(\frac{\partial f_i}{\partial x_j}(x_k) \right)$ is the Jacobian matrix of f at x_k .

In general it is very costly to compute $J(f)(x_k)$ at each iteration and then to solve the corresponding linear system. If the method converges, the consecutive vectors x_k should differ only a little, as also the corresponding matrices $J(f)(x_k)$. Thus, we are led to several variants of Newton's method.

Variant 2. This variant consists in keeping the same matrix for p consecutive steps (where p is some fixed integer ≥ 2):

$$\begin{aligned} x_{k+1} &= x_k - (f'(x_0))^{-1}(f(x_k)), & 0 \leq k \leq p-1 \\ x_{k+1} &= x_k - (f'(x_p))^{-1}(f(x_k)), & p \leq k \leq 2p-1 \\ &\vdots \\ x_{k+1} &= x_k - (f'(x_{rp}))^{-1}(f(x_k)), & rp \leq k \leq (r+1)p-1 \\ &\vdots \end{aligned}$$

Variant 3. Set $p = \infty$, that is, use *the same matrix $f'(x_0)$ for all iterations*, which leads to iterations of the form

$$x_{k+1} = x_k - (f'(x_0))^{-1}(f(x_k)), \quad k \geq 0,$$

Variant 4. Replace $f'(x_0)$ by a particular matrix A_0 which is easy to invert:

$$x_{k+1} = x_k - A_0^{-1}f(x_k), \quad k \geq 0.$$

In the last two cases, if possible, we use an LU factorization of $f'(x_0)$ or A_0 to speed up the method. In some cases, it may even possible to set $A_0 = I$.

The above considerations lead us to the definition of a *generalized Newton method*, as in Ciarlet [41] (Chapter 7). Recall that a linear map $f \in \mathcal{L}(E; F)$ is called an *isomorphism* iff f is continuous, bijective, and f^{-1} is also continuous.

Definition 41.1. If X and Y are two normed vector spaces and if $f: \Omega \rightarrow Y$ is a function from some open subset Ω of X , a *generalized Newton method* for finding zeros of f consists of

- (1) A sequence of families $(A_k(x))$ of linear isomorphisms from X to Y , for all $x \in \Omega$ and all integers $k \geq 0$;
- (2) Some starting point $x_0 \in \Omega$;

(3) A sequence (x_k) of points of Ω defined by

$$x_{k+1} = x_k - (A_k(x_\ell))^{-1}(f(x_k)), \quad k \geq 0, \quad (**)$$

where for every integer $k \geq 0$, the integer ℓ satisfies the condition

$$0 \leq \ell \leq k.$$

With $\Delta x_k = x_{k+1} - x_k$, Equation $(**)$ is equivalent to solving the equation

$$A_k(x_\ell)(\Delta x_k) = -f(x_k)$$

and setting $x_{k+1} = x_k + \Delta x_k$. The function $A_k(x)$ usually depends on f' .

Definition 41.1 gives us enough flexibility to capture all the situations that we have previously discussed:

	Function	Index
Variant 1:	$A_k(x) = f'(x),$	$\ell = k$
Variant 2:	$A_k(x) = f'(x),$	$\ell = \min\{rp, k\}$, if $rp \leq k \leq (r+1)p-1, r \geq 0$
Variant 3:	$A_k(x) = f'(x),$	$\ell = 0$
Variant 4:	$A_k(x) = A_0,$	

where A_0 is a linear isomorphism from X to Y . The first case corresponds to Newton's original method and the others to the variants that we just discussed. We could also have $A_k(x) = A_k$, a fixed linear isomorphism independent of $x \in \Omega$.

Example 41.2. Consider the matrix function f given by

$$f(X) = A - X^{-1},$$

with A and X invertible $n \times n$ matrices. If we apply Variant 1 of Newton's method starting with any $n \times n$ matrix X_0 , since the derivative of the function g given by $g(X) = X^{-1}$ is $dg_X(Y) = -X^{-1}YX^{-1}$, we have

$$f'_X(Y) = X^{-1}YX^{-1},$$

so

$$(f'_X)^{-1}(Y) = XYX$$

and the Newton step is

$$X_{k+1} = X_k - (f'_{X_k})^{-1}(f(X_k)) = X_k - X_k(A - X_k^{-1})X_k,$$

which yields the sequence (X_k) with

$$X_{k+1} = X_k(2I - AX_k), \quad k \geq 0.$$

In Problem 41.5, it is shown that Newton's method converges to A^{-1} iff the spectral radius of $I - X_0A$ is strictly smaller than 1, that is, $\rho(I - X_0A) < 1$.

The following theorem inspired by the *Newton–Kantorovich theorem* gives sufficient conditions that guarantee that the sequence (x_k) constructed by a generalized Newton method converges to a zero of f close to x_0 . Although quite technical, these conditions are not very surprising.

Theorem 41.1. *Let X be a Banach space, let $f: \Omega \rightarrow Y$ be differentiable on the open subset $\Omega \subseteq X$, and assume that there are constants $r, M, \beta > 0$ such that if we let*

$$B = \{x \in X \mid \|x - x_0\| \leq r\} \subseteq \Omega,$$

then

$$(1) \quad \sup_{k \geq 0} \sup_{x \in B} \|A_k^{-1}(x)\|_{\mathcal{L}(Y;X)} \leq M,$$

(2) $\beta < 1$ and

$$\sup_{k \geq 0} \sup_{x, x' \in B} \|f'(x) - A_k(x')\|_{\mathcal{L}(X;Y)} \leq \frac{\beta}{M}$$

(3)

$$\|f(x_0)\| \leq \frac{r}{M}(1 - \beta).$$

Then the sequence (x_k) defined by

$$x_{k+1} = x_k - A_k^{-1}(x_\ell)(f(x_k)), \quad 0 \leq \ell \leq k$$

is entirely contained within B and converges to a zero a of f , which is the only zero of f in B . Furthermore, the convergence is geometric, which means that

$$\|x_k - a\| \leq \frac{\|x_1 - x_0\|}{1 - \beta} \beta^k.$$

Proof. We follow Ciarlet [41] (Theorem 7.5.1, Section 7.5). The proof has three steps.

Step 1. We establish the following inequalities for all $k \geq 1$.

$$\|x_k - x_{k-1}\| \leq M \|f(x_{k-1})\| \tag{a}$$

$$\|x_k - x_0\| \leq r \quad (x_k \in B) \tag{b}$$

$$\|f(x_k)\| \leq \frac{\beta}{M} \|x_k - x_{k-1}\|. \tag{c}$$

We proceed by induction on k , starting with the base case $k = 1$. Since

$$x_1 = x_0 - A_0^{-1}(x_0)(f(x_0)),$$

we have $x_1 - x_0 = -A_0^{-1}(x_0)(f(x_0))$, so by (1) and (3) and since $0 < \beta < 1$, we have

$$\|x_1 - x_0\| \leq M \|f(x_0)\| \leq r(1 - \beta) \leq r,$$

establishing (a) and (b) for $k = 1$. We also have $f(x_0) = -A_0(x_0)(x_1 - x_0)$, so $-f(x_0) - A_0(x_0)(x_1 - x_0) = 0$ and thus

$$f(x_1) = f(x_1) - f(x_0) - A_0(x_0)(x_1 - x_0).$$

By the mean value theorem (Proposition 39.12) applied to the function $x \mapsto f(x) - A_0(x_0)(x)$, by (2), we get

$$\|f(x_1)\| \leq \sup_{x \in B} \|f'(x) - A_0(x_0)\| \|x_1 - x_0\| \leq \frac{\beta}{M} \|x_1 - x_0\|,$$

which is (c) for $k = 1$. We now establish the induction step.

Since by definition

$$x_k - x_{k-1} = -A_{k-1}^{-1}(x_\ell)(f(x_{k-1})), \quad 0 \leq \ell \leq k-1,$$

by (1) and the fact that by the induction hypothesis for (b), $x_\ell \in B$, we get

$$\|x_k - x_{k-1}\| \leq M \|f(x_{k-1})\|,$$

which proves (a) for k . As a consequence, since by the induction hypothesis for (c),

$$\|f(x_{k-1})\| \leq \frac{\beta}{M} \|x_{k-1} - x_{k-2}\|,$$

we get

$$\|x_k - x_{k-1}\| \leq M \|f(x_{k-1})\| \leq \beta \|x_{k-1} - x_{k-2}\|, \tag{*}_1$$

and by repeating this step,

$$\|x_k - x_{k-1}\| \leq \beta^{k-1} \|x_1 - x_0\|. \tag{*}_2$$

Using $(*)_2$ and (3), we obtain

$$\begin{aligned} \|x_k - x_0\| &\leq \sum_{j=1}^k \|x_j - x_{j-1}\| \leq \left(\sum_{j=1}^k \beta^{j-1} \right) \|x_1 - x_0\| \\ &\leq \frac{\|x_1 - x_0\|}{1 - \beta} \leq \frac{M}{1 - \beta} \|f(x_0)\| \leq r, \end{aligned}$$

which proves that $x_k \in B$, which is (b) for k .

Since

$$x_k - x_{k-1} = -A_{k-1}^{-1}(x_\ell)(f(x_{k-1}))$$

we also have $f(x_{k-1}) = -A_{k-1}(x_\ell)(x_k - x_{k-1})$, so we have

$$f(x_k) = f(x_k) - f(x_{k-1}) - A_{k-1}(x_\ell)(x_k - x_{k-1}),$$

and as in the base case, applying the mean value theorem (Proposition 39.12) to the function $x \mapsto f(x) - A_{k-1}(x_\ell)(x)$, by (2), we obtain

$$\|f(x_k)\| \leq \sup_{x \in B} \|f'(x) - A_{k-1}(x_\ell)\| \|x_k - x_{k-1}\| \leq \frac{\beta}{M} \|x_k - x_{k-1}\|,$$

proving (c) for k .

Step 2. Prove that f has a zero in B .

To do this we prove that (x_k) is a Cauchy sequence. This is because, using $(*_2)$, we have

$$\begin{aligned} \|x_{k+j} - x_k\| &\leq \sum_{i=0}^{j-1} \|x_{k+i+1} - x_{k+i}\| \leq \beta^k \left(\sum_{i=0}^{j-1} \beta^i \right) \|x_1 - x_0\| \\ &\leq \frac{\beta^k}{1-\beta} \|x_1 - x_0\|, \end{aligned}$$

for all $k \geq 0$ and all $j \geq 0$, proving that (x_k) is a Cauchy sequence. Since B is a closed ball in a complete normed vector space, B is complete and the Cauchy sequence (x_k) converges to a limit $a \in B$. Since f is continuous on Ω (because it is differentiable), by (c) we obtain

$$\|f(a)\| = \lim_{k \rightarrow \infty} \|f(x_k)\| \leq \frac{\beta}{M} \lim_{k \rightarrow \infty} \|x_k - x_{k-1}\| = 0,$$

which yields $f(a) = 0$.

Since

$$\|x_{k+j} - x_k\| \leq \frac{\beta^k}{1-\beta} \|x_1 - x_0\|,$$

if we let j tend to infinity, we obtain the inequality

$$\|x_k - a\| = \|a - x_k\| \leq \frac{\beta^k}{1-\beta} \|x_1 - x_0\|,$$

which is the last statement of the theorem.

Step 3. Prove that f has a unique zero in B .

Suppose $f(a) = f(b) = 0$ with $a, b \in B$. Since $A_0^{-1}(x_0)(A_0(x_0)(b-a)) = b-a$, we have

$$b-a = -A_0^{-1}(x_0)(f(b) - f(a) - A_0(x_0)(b-a)),$$

which by (1) and (2) and the mean value theorem implies that

$$\|b-a\| \leq \|A_0^{-1}(x_0)\| \sup_{x \in B} \|f'(x) - A_0(x_0)\| \|b-a\| \leq \beta \|b-a\|.$$

Since $0 < \beta < 1$, the inequality $\|b-a\| \leq \beta \|b-a\|$ is only possible if $a=b$. \square

It should be observed that the conditions of Theorem 41.1 are typically quite stringent. It can be shown that Theorem 41.1 applies to the function f of Example 41.1 given by $f(x) = x^2 - \alpha$ with $\alpha > 0$, for any $x_0 > 0$ such that

$$\frac{6}{7}\alpha \leq x_0^2 \leq \frac{6}{5}\alpha,$$

with $\beta = 2/5$, $r = (1/6)x_0$, $M = 3/(5x_0)$. Such values of x_0 are quite close to $\sqrt{\alpha}$.

If we assume that we already know that some element $a \in \Omega$ is a zero of f , the next theorem gives sufficient conditions for a special version of a generalized Newton method to converge. For this special method the linear isomorphisms $A_k(x)$ are independent of $x \in \Omega$.

Theorem 41.2. *Let X be a Banach space and let $f: \Omega \rightarrow Y$ be differentiable on the open subset $\Omega \subseteq X$. If $a \in \Omega$ is a point such that $f(a) = 0$, if $f'(a)$ is a linear isomorphism, and if there is some λ with $0 < \lambda < 1/2$ such that*

$$\sup_{k \geq 0} \|A_k - f'(a)\|_{\mathcal{L}(X;Y)} \leq \frac{\lambda}{\|(f'(a))^{-1}\|_{\mathcal{L}(Y;X)}},$$

then there is a closed ball B of center a such that for every $x_0 \in B$, the sequence (x_k) defined by

$$x_{k+1} = x_k - A_k^{-1}(f(x_k)), \quad k \geq 0,$$

is entirely contained within B and converges to a , which is the only zero of f in B . Furthermore, the convergence is geometric, which means that

$$\|x_k - a\| \leq \beta^k \|x_0 - a\|,$$

for some $\beta < 1$.

A proof of Theorem 41.2 can be found in Ciarlet [41] (Section 7.5).

For the sake of completeness, we state a version of the Newton–Kantorovich theorem which corresponds to the case where $A_k(x) = f'(x)$. In this instance, a stronger result can be obtained especially regarding upper bounds, and we state a version due to Gragg and Tapia which appears in Problem 7.5-4 of Ciarlet [41].

Theorem 41.3. (Newton–Kantorovich) *Let X be a Banach space, and let $f: \Omega \rightarrow Y$ be differentiable on the open subset $\Omega \subseteq X$. Assume that there exist three positive constants λ, μ, ν and a point $x_0 \in \Omega$ such that*

$$0 < \lambda\mu\nu \leq \frac{1}{2},$$

and if we let

$$\begin{aligned}\rho^- &= \frac{1 - \sqrt{1 - 2\lambda\mu\nu}}{\mu\nu} \\ \rho^+ &= \frac{1 + \sqrt{1 - 2\lambda\mu\nu}}{\mu\nu} \\ B &= \{x \in X \mid \|x - x_0\| < \rho^-\} \\ \Omega^+ &= \{x \in \Omega \mid \|x - x_0\| < \rho^+\},\end{aligned}$$

then $\overline{B} \subseteq \Omega$, $f'(x_0)$ is an isomorphism of $\mathcal{L}(X; Y)$, and

$$\begin{aligned}\|(f'(x_0))^{-1}\| &\leq \mu, \\ \|(f'(x_0))^{-1}f(x_0)\| &\leq \lambda, \\ \sup_{x,y \in \Omega^+} \|f'(x) - f'(y)\| &\leq \nu \|x - y\|.\end{aligned}$$

Then $f'(x)$ is isomorphism of $\mathcal{L}(X; Y)$ for all $x \in B$, and the sequence defined by

$$x_{k+1} = x_k - (f'(x_k))^{-1}(f(x_k)), \quad k \geq 0$$

is entirely contained within the ball B and converges to a zero a of f which is the only zero of f in Ω^+ . Finally, if we write $\theta = \rho^-/\rho^+$, then we have the following bounds:

$$\begin{aligned}\|x_k - a\| &\leq \frac{2\sqrt{1 - 2\lambda\mu\nu}}{\lambda\mu\nu} \frac{\theta^{2k}}{1 - \theta^{2k}} \|x_1 - x_0\| && \text{if } \lambda\mu\nu < \frac{1}{2} \\ \|x_k - a\| &\leq \frac{\|x_1 - x_0\|}{2^{k-1}} && \text{if } \lambda\mu\nu = \frac{1}{2},\end{aligned}$$

and

$$\frac{2 \|x_{k+1} - x_k\|}{1 + \sqrt{(1 + 4\theta^{2k})(1 + \theta^{2k})^{-2}}} \leq \|x_k - a\| \leq \theta^{2k-1} \|x_k - x_{k-1}\|.$$

We can now specialize Theorems 41.1 and 41.2 to the search of zeros of the derivative $J': \Omega \rightarrow E'$, of a function $J: \Omega \rightarrow \mathbb{R}$, with $\Omega \subseteq E$. The second derivative J'' of J is a continuous bilinear form $J'': E \times E \rightarrow \mathbb{R}$, but it is convenient to view it as a linear map in $\mathcal{L}(E, E')$; the continuous linear form $J''(u)$ is given by $J''(u)(v) = J''(u, v)$. In our next theorem, which follows immediately from Theorem 41.1, we assume that the $A_k(x)$ are isomorphisms in $\mathcal{L}(E, E')$.

Theorem 41.4. *Let E be a Banach space, let $J: \Omega \rightarrow \mathbb{R}$ be twice differentiable on the open subset $\Omega \subseteq E$, and assume that there are constants $r, M, \beta > 0$ such that if we let*

$$B = \{x \in E \mid \|x - x_0\| \leq r\} \subseteq \Omega,$$

then

(1)

$$\sup_{k \geq 0} \sup_{x \in B} \|A_k^{-1}(x)\|_{\mathcal{L}(E'; E)} \leq M,$$

(2) $\beta < 1$ and

$$\sup_{k \geq 0} \sup_{x, x' \in B} \|J''(x) - A_k(x')\|_{\mathcal{L}(E; E')} \leq \frac{\beta}{M}$$

(3)

$$\|J'(x_0)\| \leq \frac{r}{M}(1 - \beta).$$

Then the sequence (x_k) defined by

$$x_{k+1} = x_k - A_k^{-1}(x_\ell)(J'(x_k)), \quad 0 \leq \ell \leq k$$

is entirely contained within B and converges to a zero a of J' , which is the only zero of J' in B . Furthermore, the convergence is geometric, which means that

$$\|x_k - a\| \leq \frac{\|x_1 - x_0\|}{1 - \beta} \beta^k.$$

In the next theorem, which follows immediately from Theorem 41.2, we assume that the $A_k(x)$ are isomorphisms in $\mathcal{L}(E, E')$ that are independent of $x \in \Omega$.

Theorem 41.5. *Let E be a Banach space and let $J: \Omega \rightarrow \mathbb{R}$ be twice differentiable on the open subset $\Omega \subseteq E$. If $a \in \Omega$ is a point such that $J'(a) = 0$, if $J''(a)$ is a linear isomorphism, and if there is some λ with $0 < \lambda < 1/2$ such that*

$$\sup_{k \geq 0} \|A_k - J''(a)\|_{\mathcal{L}(E; E')} \leq \frac{\lambda}{\|(J''(a))^{-1}\|_{\mathcal{L}(E'; E)}},$$

then there is a closed ball B of center a such that for every $x_0 \in B$, the sequence (x_k) defined by

$$x_{k+1} = x_k - A_k^{-1}(J'(x_k)), \quad k \geq 0,$$

is entirely contained within B and converges to a , which is the only zero of J' in B . Furthermore, the convergence is geometric, which means that

$$\|x_k - a\| \leq \beta^k \|x_0 - a\|,$$

for some $\beta < 1$.

When $E = \mathbb{R}^n$, the Newton method given by Theorem 41.4 yields an iteration step of the form

$$x_{k+1} = x_k - A_k^{-1}(x_\ell) \nabla J(x_k), \quad 0 \leq \ell \leq k,$$

where $\nabla J(x_k)$ is the gradient of J at x_k (here, we identify E' with \mathbb{R}^n). In particular, Newton's original method picks $A_k = J''$, and the iteration step is of the form

$$x_{k+1} = x_k - (\nabla^2 J(x_k))^{-1} \nabla J(x_k), \quad k \geq 0,$$

where $\nabla^2 J(x_k)$ is the Hessian of J at x_k .

Example 41.3. Let us apply Newton's original method to the function J given by $J(x) = \frac{1}{3}x^3 - 4x$. We have $J'(x) = x^2 - 4$ and $J''(x) = 2x$, so the Newton step is given by

$$x_{k+1} = x_k - \frac{x_k^2 - 4}{2x_k} = \frac{1}{2} \left(x_k + \frac{4}{x_k} \right).$$

This is the sequence of Example 41.1 to compute the square root of 4. Starting with any $x_0 > 0$ it converges very quickly to 2.

As remarked in Ciarlet [41] (Section 7.5), generalized Newton methods have a very wide range of applicability. For example, various versions of gradient descent methods can be viewed as instances of Newton method. See Section 49.9 for an example.

Newton's method also plays an important role in convex optimization, in particular, interior-point methods. A variant of Newton's method dealing with equality constraints has been developed. We refer the reader to Boyd and Vandenberghe [29], Chapters 10 and 11, for a comprehensive exposition of these topics.

41.3 Summary

The main concepts and results of this chapter are listed below:

- Newton's method for functions $f: \mathbb{R} \rightarrow \mathbb{R}$.
- Generalized Newton methods.
- The *Newton-Kantorovich* theorem.

41.4 Problems

Problem 41.1. If $\alpha > 0$ and $f(x) = x^2 - \alpha$, Newton's method yields the sequence

$$x_{k+1} = \frac{1}{2} \left(x_k + \frac{\alpha}{x_k} \right)$$

to compute the square root $\sqrt{\alpha}$ of α .

(1) Prove that if $x_0 > 0$, then $x_k > 0$ and

$$\begin{aligned}x_{k+1} - \sqrt{\alpha} &= \frac{1}{2x_k}(x_k - \sqrt{\alpha})^2 \\x_{k+2} - x_{k+1} &= \frac{1}{2x_{k+1}}(\alpha - x_{k+1}^2)\end{aligned}$$

for all $k \geq 0$. Deduce that Newton's method converges to $\sqrt{\alpha}$ for any $x_0 > 0$.

(2) Prove that if $x_0 < 0$, then Newton's method converges to $-\sqrt{\alpha}$.

Problem 41.2. (1) If $\alpha > 0$ and $f(x) = x^2 - \alpha$, show that the conditions of Theorem 41.1 are satisfied by any $\beta \in (0, 1)$ and any x_0 such that

$$|x_0^2 - \alpha| \leq \frac{4\beta(1 - \beta)}{(\beta + 2)^2}x_0^2,$$

with

$$r = \frac{\beta}{\beta + 2}x_0, \quad M = \frac{\beta + 2}{4x_0}.$$

(2) Prove that the maximum of the function defined on $[0, 1]$ by

$$\beta \mapsto \frac{4\beta(1 - \beta)}{(\beta + 2)^2}$$

has a maximum for $\beta = 2/5$. For this value of β , check that $r = (1/6)x_0$, $M = 3/(5x_0)$, and

$$\frac{6}{7}\alpha \leq x_0^2 \leq \frac{6}{5}\alpha.$$

Problem 41.3. Consider generalizing Problem 41.1 to the matrix function f given by $f(X) = X^2 - C$, where X and C are two real $n \times n$ matrices with C symmetric positive definite. The first step is to determine for which A does the inverse df_A^{-1} exist. Let g be the function given by $g(X) = X^2$. From Problem 39.1 we know that the derivative at A of the function g is $dg_A(X) = AX + XA$, and obviously $df_A = dg_A$. Thus we are led to figure out when the linear matrix map $X \mapsto AX + XA$ is invertible. This can be done using the Kronecker product.

Given an $m \times n$ matrix $A = (a_{ij})$ and a $p \times q$ matrix $B = (b_{ij})$, the *Kronecker product* (or *tensor product*) $A \otimes B$ of A and B is the $mp \times nq$ matrix

$$A \otimes B = \begin{pmatrix} a_{11}B & a_{12}B & \cdots & a_{1n}B \\ a_{21}B & a_{22}B & \cdots & a_{2n}B \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1}B & a_{m2}B & \cdots & a_{mn}B \end{pmatrix}.$$

It can be shown (and you may use these facts without proof) that \otimes is associative and that

$$(A \otimes B)(C \otimes D) = AC \otimes BD$$

$$(A \otimes B)^\top = A^\top \otimes B^\top,$$

whenever AC and BD are well defined.

Given any $n \times n$ matrix X , let $\text{vec}(X)$ be the vector in \mathbb{R}^{n^2} obtained by concatenating the *rows* of X .

(1) Prove that $AX = Y$ iff

$$(A \otimes I_n)\text{vec}(X) = \text{vec}(Y)$$

and $XA = Y$ iff

$$(I_n \otimes A^\top)\text{vec}(X) = \text{vec}(Y).$$

Deduce that $AX + XA = Y$ iff

$$((A \otimes I_n) + (I_n \otimes A^\top))\text{vec}(X) = \text{vec}(Y).$$

In the case where $n = 2$ and if we write

$$A = \begin{pmatrix} a & b \\ c & d \end{pmatrix},$$

check that

$$A \otimes I_2 + I_2 \otimes A^\top = \begin{pmatrix} 2a & c & b & 0 \\ b & a+d & 0 & b \\ c & 0 & a+d & c \\ 0 & c & b & 2d \end{pmatrix}.$$

The problem is determine when the matrix $(A \otimes I_n) + (I_n \otimes A^\top)$ is invertible.

Remark: The equation $AX + XA = Y$ is a special case of the equation $AX + XB = C$ (sometimes written $AX - XB = C$), called the *Sylvester equation*, where A is an $m \times m$ matrix, B is an $n \times n$ matrix, and X, C are $m \times n$ matrices; see Higham [91] (Appendix B).

(2) In the case where $n = 2$, prove that

$$\det(A \otimes I_2 + I_2 \otimes A^\top) = 4(a+d)^2(ad-bc).$$

(3) Let A and B be any two $n \times n$ complex matrices. Use Schur factorizations $A = UT_1U^*$ and $B = VT_2V^*$ (where U and V are unitary and T_1, T_2 are upper-triangular) to prove that if $\lambda_1, \dots, \lambda_n$ are the eigenvalues of A and μ_1, \dots, μ_n are the eigenvalues of B , then the scalars $\lambda_i\mu_j$ are the eigenvalues of $A \otimes B$, for $i, j = 1, \dots, n$.

Hint. Check that $U \otimes V$ is unitary and that $T_1 \otimes T_2$ is upper triangular.

(4) Prove that the eigenvalues of $(A \otimes I_n) + (I_n \otimes B)$ are the scalars $\lambda_i + \mu_j$, for $i, j = 1, \dots, n$. Deduce that the eigenvalues of $(A \otimes I_n) + (I_n \otimes A^\top)$ are $\lambda_i + \lambda_j$, for $i, j = 1, \dots, n$. Thus $(A \otimes I_n) + (I_n \otimes A^\top)$ is invertible iff $\lambda_i + \lambda_j \neq 0$, for $i, j = 1, \dots, n$. In particular, prove that if A is symmetric positive definite, then so is $(A \otimes I_n) + (I_n \otimes A^\top)$.

Hint. Use (3).

(5) Prove that if A and B are symmetric and $(A \otimes I_n) + (I_n \otimes A^\top)$ is invertible, then the unique solution X of the equation $AX + XA = B$ is symmetric.

(6) Starting with a symmetric positive definite matrix X_0 , the general step of Newton's method is

$$X_{k+1} = X_k - (f'_{X_k})^{-1}(X_k^2 - C) = X_k - (g'_{X_k})^{-1}(X_k^2 - C),$$

and since g'_{X_k} is linear, this is equivalent to

$$X_{k+1} = X_k - (g'_{X_k})^{-1}(X_k^2) + (g'_{X_k})^{-1}(C).$$

But since X_k is SPD, $(g'_{X_k})^{-1}(X_k^2)$ is the unique solution of

$$X_k Y + Y X_k = X_k^2$$

whose solution is obviously $Y = (1/2)X_k$. Therefore the Newton step is

$$X_{k+1} = X_k - (g'_{X_k})^{-1}(X_k^2) + (g'_{X_k})^{-1}(C) = X_k - \frac{1}{2}X_k + (g'_{X_k})^{-1}(C) = \frac{1}{2}X_k + (g'_{X_k})^{-1}(C),$$

so we have

$$X_{k+1} = \frac{1}{2}X_k + (g'_{X_k})^{-1}(C) = (g'_{X_k})^{-1}(X_k^2 + C).$$

Prove that if X_k and C are symmetric positive definite, then $(g'_{X_k})^{-1}(C)$ is symmetric positive definite, and if C is symmetric positive semidefinite, then $(g'_{X_k})^{-1}(C)$ is symmetric positive semidefinite.

Hint. By (5) the unique solution Z of the equation $X_k Z + Z X_k = C$ (where C is symmetric) is symmetric so it can be diagonalized as $Z = Q D Q^\top$ with Q orthogonal and D a real diagonal matrix. Prove that

$$Q^\top X_k Q D + D Q^\top X_k Q = Q^\top C Q,$$

and solve the system using the diagonal elements.

Deduce that if X_k and C are SPD, then X_{k+1} is SPD.

Since $C = P \Sigma P^\top$ is SPD, it has an SPD square root (in fact unique) $C^{1/2} = P \Sigma^{1/2} P^\top$. Prove that

$$X_{k+1} - C^{1/2} = (g'_{X_k})^{-1}(X_k - C^{1/2})^2.$$

Prove that

$$\|(g'_{X_k})^{-1}\|_2 = \frac{1}{2\|X_k\|_2}.$$

Since

$$X_{k+1} - X_k = (g'_{X_k})^{-1}(C - X_k^2),$$

deduce that if $X_k \neq C^2$, then $X_k - X_{k+1}$ is SPD.

Open problem: Does Theorem 41.1 apply for some suitable r, M, β ?

(7) Prove that if C and X_0 commute, provided that the equation $X_k Z + ZX_k = C$ has a unique solution for all k , then X_k and C commute for all k and Z is given by

$$Z = \frac{1}{2}X_k^{-1}C = \frac{1}{2}CX_k^{-1}.$$

Deduce that

$$X_{k+1} = \frac{1}{2}(X_k + X_k^{-1}C) = \frac{1}{2}(X_k + CX_k^{-1}).$$

This is the matrix analog of the formula given in Problem 41.1(1).

Prove that if C and X_0 have positive eigenvalues and C and X_0 commute, then X_{k+1} has positive eigenvalues for all $k \geq 0$ and thus the sequence (X_k) is defined.

Hint. Because X_k and C commute, X_k^{-1} and C commute, and obviously X_k and X_k^{-1} commute. By Proposition 31.9, X_k , X_k^{-1} , and C are triangulable in a common basis, so there is some orthogonal matrix P and some upper-triangular matrices T_1, T_2 such that

$$X_k = PT_1P^\top, \quad X_k^{-1} = PT_1^{-1}P^\top, \quad C = PT_2P^\top.$$

It follows that

$$X_{k+1} = \frac{1}{2}P(T_1 + T_1^{-1}T_2)P^\top.$$

Also recall that the diagonal entries of an upper-triangular matrix are the eigenvalues of that matrix.

We conjecture that if C has positive eigenvalues, then the Newton sequence converges starting with any X_0 of the form $X_0 = \mu I_n$, with $\mu > 0$.

(8) Implement the above method in **Matlab** (there is a command **kron(A, B)** to form the Kronecker product of A and B). Test your program on diagonalizable and nondiagonalizable matrices, including

$$W = \begin{pmatrix} 10 & 7 & 8 & 7 \\ 7 & 5 & 6 & 5 \\ 8 & 6 & 10 & 9 \\ 7 & 5 & 9 & 10 \end{pmatrix}, \quad A_1 = \begin{pmatrix} 5 & 4 & 1 & 1 \\ 4 & 5 & 1 & 1 \\ 1 & 1 & 4 & 2 \\ 1 & 1 & 2 & 4 \end{pmatrix},$$

and

$$A_2 = \begin{pmatrix} 1 & 0 & 0 & 0 \\ -1 & 0.01 & 0 & 0 \\ -1 & -1 & 100 & 100 \\ -1 & -1 & -100 & 100 \end{pmatrix}, \quad A_3 = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 0 & 1 & 1 & 1 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad A_4 = \begin{pmatrix} 1 & -1 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & -1 \\ 0 & 0 & 1 & 1 \end{pmatrix}.$$

What happens with

$$C = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}, \quad X_0 = \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}.$$

The problem of determining when square roots of matrices exist and procedures for finding them are thoroughly investigated in Higham [91] (Chapter 6).

Problem 41.4. (1) Show that Newton's method applied to the function

$$f(x) = \alpha - \frac{1}{x}$$

with $\alpha \neq 0$ and $x \in \mathbb{R} - \{0\}$ yields the sequence (x_k) with

$$x_{k+1} = x_k(2 - \alpha x_k), \quad k \geq 0.$$

(2) If we let $r_k = 1 - \alpha x_k$, prove that $r_{k+1} = r_k^2$ for all $k \geq 0$. Deduce that Newton's method converges to $1/\alpha$ if $0 < \alpha x_0 < 2$.

Problem 41.5. (1) Show that Newton's method applied to the matrix function

$$f(X) = A - X^{-1},$$

with A and X invertible $n \times n$ matrices and started with any $n \times n$ matrix X_0 yields the sequence (X_k) with

$$X_{k+1} = X_k(2I - AX_k), \quad k \geq 0.$$

(2) If we let $R_k = I - AX_k$, prove that

$$R_{k+1} = I - (I - R_k)(I + R_k) = R_k^2$$

for all $k \geq 0$. Deduce that Newton's method converges to A^{-1} iff the spectral radius of $I - AX_0$ is strictly smaller than 1, that is, $\rho(I - AX_0) < 1$.

(3) Assume that A is symmetric positive definite and let $X_0 = \mu I$. Prove that the condition $\rho(I - AX_0) < 1$ is equivalent to

$$0 < \mu < \frac{2}{\rho(A)}.$$

(4) Write a **Matlab** program implementing Newton's method specified in (1). Test your program with the $n \times n$ matrix

$$A_n = \begin{pmatrix} 2 & -1 & 0 & \cdots & 0 \\ -1 & 2 & -1 & \cdots & 0 \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & \cdots & -1 & 2 & -1 \\ 0 & \cdots & 0 & -1 & 2 \end{pmatrix},$$

and with $X_0 = \mu I_n$, for various values of n , including $n = 8, 10, 20$, and various values of μ such that $0 < \mu \leq 1/2$. Find some $\mu > 1/2$ causing divergence.

Problem 41.6. A method for computing the n th root $x^{1/n}$ of a positive real number $x \in \mathbb{R}$, with $n \in \mathbb{N}$ a positive integer $n \geq 2$, proceeds as follows: define the sequence (x_k) , where x_0 is any chosen positive real, and

$$x_{k+1} = \frac{1}{n} \left((n-1)x_k + \frac{x}{x_k^{n-1}} \right), \quad k \geq 0.$$

(1) Implement the above method in **Matlab** and test it for various input values of x , x_0 , and of $n \geq 2$, by running successively your program for $m = 2, 3, \dots, 100$ iterations. Have your program plot the points (i, x_i) to watch how quickly the sequence converges.

Experiment with various choices of x_0 . One of these choices should be $x_0 = x$. Compare your answers with the result of applying the of **Matlab** function $x \mapsto x^{1/n}$.

In some case, when x_0 is small, the number of iterations has to be at least 1000. Exhibit this behavior.

Problem 41.7. Refer to Problem 41.6 for the definition of the sequence (x_k) .

(1) Define the *relative error* ϵ_k as

$$\epsilon_k = \frac{x_k}{x^{1/n}} - 1, \quad k \geq 0.$$

Prove that

$$\epsilon_{k+1} = \frac{x^{(1-1/n)}}{nx_k^{n-1}} \left(\frac{(n-1)x_k^n}{x} - \frac{nx_k^{n-1}}{x^{(1-1/n)}} + 1 \right),$$

and then that

$$\epsilon_{k+1} = \frac{1}{n(\epsilon_k + 1)^{n-1}} (\epsilon_k(\epsilon_k + 1)^{n-2}((n-1)\epsilon_k + (n-2)) + 1 - (\epsilon_k + 1)^{n-2}),$$

for all $k \geq 0$.

(2) Since

$$\epsilon_k + 1 = \frac{x_k}{x^{1/n}},$$

and since we assumed $x_0, x > 0$, we have $\epsilon_0 + 1 > 0$. We would like to prove that

$$\epsilon_k \geq 0, \quad \text{for all } k \geq 1.$$

For this consider the variations of the function f given by

$$f(u) = (n-1)u^n - nx^{1/n}u^{n-1} + x,$$

for $u \in \mathbb{R}$.

Use the above to prove that $f(u) \geq 0$ for all $u \geq 0$. Conclude that

$$\epsilon_k \geq 0, \quad \text{for all } k \geq 1.$$

(3) Prove that if $n = 2$, then

$$0 \leq \epsilon_{k+1} = \frac{\epsilon_k^2}{2(\epsilon_k + 1)}, \quad \text{for all } k \geq 0,$$

else if $n \geq 3$, then

$$0 \leq \epsilon_{k+1} \leq \frac{(n-1)}{n} \epsilon_k, \quad \text{for all } k \geq 1.$$

Prove that the sequence (x_k) converges to $x^{1/n}$ for every initial value $x_0 > 0$.

(4) When $n = 2$, we saw in Problem 41.7(3) that

$$0 \leq \epsilon_{k+1} = \frac{\epsilon_k^2}{2(\epsilon_k + 1)}, \quad \text{for all } k \geq 0.$$

For $n = 3$, prove that

$$\epsilon_{k+1} = \frac{2\epsilon_k^2(3/2 + \epsilon_k)}{3(\epsilon_k + 1)^2}, \quad \text{for all } k \geq 0,$$

and for $n = 4$, prove that

$$\epsilon_{k+1} = \frac{3\epsilon_k^2}{4(\epsilon_k + 1)^3} (2 + (8/3)\epsilon_k + \epsilon_k^2), \quad \text{for all } k \geq 0.$$

Let μ_3 and μ_4 be the functions given by

$$\begin{aligned} \mu_3(a) &= \frac{3}{2} + a \\ \mu_4(a) &= 2 + \frac{8}{3}a + a^2, \end{aligned}$$

so that if $n = 3$, then

$$\epsilon_{k+1} = \frac{2\epsilon_k^2\mu_3(\epsilon_k)}{3(\epsilon_k + 1)^2}, \quad \text{for all } k \geq 0,$$

and if $n = 4$, then

$$\epsilon_{k+1} = \frac{3\epsilon_k^2\mu_4(\epsilon_k)}{4(\epsilon_k + 1)^3}, \quad \text{for all } k \geq 0.$$

Prove that

$$a\mu_3(a) \leq (a + 1)^2 - 1, \quad \text{for all } a \geq 0,$$

and

$$a\mu_4(a) \leq (a + 1)^3 - 1, \quad \text{for all } a \geq 0.$$

Let $\eta_{3,k} = \mu_3(\epsilon_1)\epsilon_k$ when $n = 3$, and $\eta_{4,k} = \mu_4(\epsilon_1)\epsilon_k$ when $n = 4$. Prove that

$$\eta_{3,k+1} \leq \frac{2}{3}\eta_{3,k}^2, \quad \text{for all } k \geq 1,$$

and

$$\eta_{4,k+1} \leq \frac{3}{4}\eta_{4,k}^2, \quad \text{for all } k \geq 1.$$

Deduce from the above that the rate of convergence of $\eta_{i,k}$ is very fast, for $i = 3, 4$ (and $k \geq 1$).

Remark: If we let $\mu_2(a) = a$ for all a and $\eta_{2,k} = \epsilon_k$, we then proved that

$$\eta_{2,k+1} \leq \frac{1}{2}\eta_{2,k}^2, \quad \text{for all } k \geq 1.$$

Problem 41.8. This is a continuation of Problem 41.7.

(1) Prove that for all $n \geq 2$, we have

$$\epsilon_{k+1} = \left(\frac{n-1}{n} \right) \frac{\epsilon_k^2 \mu_n(\epsilon_k)}{(\epsilon_k + 1)^{n-1}}, \quad \text{for all } k \geq 0,$$

where μ_n is given by

$$\begin{aligned} \mu_n(a) = \frac{1}{2}n + \sum_{j=1}^{n-4} \frac{1}{n-1} & \left((n-1)\binom{n-2}{j} + (n-2)\binom{n-2}{j+1} - \binom{n-2}{j+2} \right) a^j \\ & + \frac{n(n-2)}{n-1} a^{n-3} + a^{n-2}. \end{aligned}$$

Furthermore, prove that μ_n can be expressed as

$$\mu_n(a) = \frac{1}{2}n + \frac{n(n-2)}{3}a + \sum_{j=2}^{n-4} \frac{(j+1)n}{(j+2)(n-1)} \binom{n-1}{j+1} a^j + \frac{n(n-2)}{n-1} a^{n-3} + a^{n-2}.$$

(2) Prove that for every j , with $1 \leq j \leq n-1$, the coefficient of a^j in $a\mu_n(a)$ is less than or equal to the coefficient of a^j in $(a+1)^{n-1} - 1$, and thus

$$a\mu_n(a) \leq (a+1)^{n-1} - 1, \quad \text{for all } a \geq 0,$$

with strict inequality if $n \geq 3$. In fact, prove that if $n \geq 3$, then for every j , with $3 \leq j \leq n-2$, the coefficient of a^j in $a\mu_n(a)$ is strictly less than the coefficient of a^j in $(a+1)^{n-1} - 1$, and if $n \geq 4$, this also holds for $j = 2$.

Let $\eta_{n,k} = \mu_n(\epsilon_1)\epsilon_k$ ($n \geq 2$). Prove that

$$\eta_{n,k+1} \leq \left(\frac{n-1}{n} \right) \eta_{n,k}^2, \quad \text{for all } k \geq 1.$$

Chapter 42

Quadratic Optimization Problems

In this chapter we consider two classes of quadratic optimization problems that appear frequently in engineering and in computer science (especially in computer vision):

1. Minimizing

$$Q(x) = \frac{1}{2}x^\top Ax - x^\top b$$

over all $x \in \mathbb{R}^n$, or subject to linear or affine constraints.

2. Minimizing

$$Q(x) = \frac{1}{2}x^\top Ax - x^\top b$$

over the unit sphere.

In both cases, A is a **symmetric matrix**. We also seek necessary and sufficient conditions for Q to have a global minimum.

42.1 Quadratic Optimization: The Positive Definite Case

Many problems in physics and engineering can be stated as the minimization of some energy function, with or without constraints. Indeed, it is a fundamental principle of mechanics that nature acts so as to minimize energy. Furthermore, if a physical system is in a stable state of equilibrium, then the energy in that state should be minimal. For example, a small ball placed on top of a sphere is in an unstable equilibrium position. A small motion causes the ball to roll down. On the other hand, a ball placed inside and at the bottom of a sphere is in a stable equilibrium position because the potential energy is minimal.

The simplest kind of energy function is a quadratic function. Such functions can be conveniently defined in the form

$$Q(x) = x^\top Ax - x^\top b,$$

where A is a symmetric $n \times n$ matrix and x, b , are vectors in \mathbb{R}^n , viewed as column vectors. Actually, for reasons that will be clear shortly, it is preferable to put a factor $\frac{1}{2}$ in front of the quadratic term, so that

$$Q(x) = \frac{1}{2}x^\top Ax - x^\top b.$$

The question is, under what conditions (on A) does $Q(x)$ have a global minimum, preferably unique?

We give a complete answer to the above question in two stages:

1. In this section we show that if A is symmetric positive definite, then $Q(x)$ has a unique global minimum precisely when

$$Ax = b.$$

2. In Section 42.2 we give necessary and sufficient conditions in the general case, in terms of the pseudo-inverse of A .

We begin with the matrix version of Definition 22.2.

Definition 42.1. A symmetric *positive definite matrix* is a matrix whose eigenvalues are strictly positive, and a symmetric *positive semidefinite matrix* is a matrix whose eigenvalues are nonnegative.

Equivalent criteria are given in the following proposition.

Proposition 42.1. *Given any Euclidean space E of dimension n , the following properties hold:*

- (1) *Every self-adjoint linear map $f: E \rightarrow E$ is positive definite iff*

$$\langle f(x), x \rangle > 0$$

for all $x \in E$ with $x \neq 0$.

- (2) *Every self-adjoint linear map $f: E \rightarrow E$ is positive semidefinite iff*

$$\langle f(x), x \rangle \geq 0$$

for all $x \in E$.

Proof. (1) First assume that f is positive definite. Recall that every self-adjoint linear map has an orthonormal basis (e_1, \dots, e_n) of eigenvectors, and let $\lambda_1, \dots, \lambda_n$ be the corresponding eigenvalues. With respect to this basis, for every $x = x_1e_1 + \dots + x_ne_n \neq 0$, we have

$$\langle f(x), x \rangle = \left\langle f\left(\sum_{i=1}^n x_i e_i\right), \sum_{i=1}^n x_i e_i \right\rangle = \left\langle \sum_{i=1}^n \lambda_i x_i e_i, \sum_{i=1}^n x_i e_i \right\rangle = \sum_{i=1}^n \lambda_i x_i^2,$$

which is strictly positive, since $\lambda_i > 0$ for $i = 1, \dots, n$, and $x_i^2 > 0$ for some i , since $x \neq 0$.

Conversely, assume that

$$\langle f(x), x \rangle > 0$$

for all $x \neq 0$. Then for $x = e_i$, we get

$$\langle f(e_i), e_i \rangle = \langle \lambda_i e_i, e_i \rangle = \lambda_i,$$

and thus $\lambda_i > 0$ for all $i = 1, \dots, n$.

(2) As in (1), we have

$$\langle f(x), x \rangle = \sum_{i=1}^n \lambda_i x_i^2,$$

and since $\lambda_i \geq 0$ for $i = 1, \dots, n$ because f is positive semidefinite, we have $\langle f(x), x \rangle \geq 0$, as claimed. The converse is as in (1) except that we get only $\lambda_i \geq 0$ since $\langle f(e_i), e_i \rangle \geq 0$. \square

Some special notation is customary (especially in the field of convex optimization) to express that a symmetric matrix is positive definite or positive semidefinite.

Definition 42.2. Given any $n \times n$ symmetric matrix A we write $A \succeq 0$ if A is positive semidefinite and we write $A \succ 0$ if A is positive definite.

Remark: It should be noted that we can define the relation

$$A \succeq B$$

between any two $n \times n$ matrices (symmetric or not) iff $A - B$ is symmetric positive semidefinite. It is easy to check that this relation is actually a partial order on matrices, called the *positive semidefinite cone ordering*; for details, see Boyd and Vandenberghe [29], Section 2.4.

If A is symmetric positive definite, it is easily checked that A^{-1} is also symmetric positive definite. Also, if C is a symmetric positive definite $m \times m$ matrix and A is an $m \times n$ matrix of rank n (and so $m \geq n$ and the map $x \mapsto Ax$ is injective), then $A^\top C A$ is symmetric positive definite.

We can now prove that

$$Q(x) = \frac{1}{2}x^\top Ax - x^\top b$$

has a global minimum when A is symmetric positive definite.

Proposition 42.2. *Given a quadratic function*

$$Q(x) = \frac{1}{2}x^\top Ax - x^\top b,$$

if A is symmetric positive definite, then $Q(x)$ has a unique global minimum for the solution $x_0 = A^{-1}b$ of the linear system $Ax = b$. The minimum value of $Q(x)$ is

$$Q(A^{-1}b) = -\frac{1}{2}b^\top A^{-1}b.$$

Proof. Since A is positive definite, it is invertible since its eigenvalues are all strictly positive. Let $x_0 = A^{-1}b$, and compute $Q(y) - Q(x_0)$ for any $y \in \mathbb{R}^n$. Since $Ax_0 = b$, we get

$$\begin{aligned} Q(y) - Q(x_0) &= \frac{1}{2}y^\top Ay - y^\top b - \frac{1}{2}x_0^\top Ax_0 + x_0^\top b \\ &= \frac{1}{2}y^\top Ay - y^\top Ax_0 + \frac{1}{2}x_0^\top Ax_0 \\ &= \frac{1}{2}(y - x_0)^\top A(y - x_0). \end{aligned}$$

Since A is positive definite, the last expression is nonnegative, and thus

$$Q(y) \geq Q(x_0)$$

for all $y \in \mathbb{R}^n$, which proves that $x_0 = A^{-1}b$ is a global minimum of $Q(x)$. A simple computation yields

$$Q(A^{-1}b) = -\frac{1}{2}b^\top A^{-1}b.$$

□

Remarks:

- (1) The quadratic function $Q(x)$ is also given by

$$Q(x) = \frac{1}{2}x^\top Ax - b^\top x,$$

but the definition using $x^\top b$ is more convenient for the proof of Proposition 42.2.

- (2) If $Q(x)$ contains a constant term $c \in \mathbb{R}$, so that

$$Q(x) = \frac{1}{2}x^\top Ax - x^\top b + c,$$

the proof of Proposition 42.2 still shows that $Q(x)$ has a unique global minimum for $x = A^{-1}b$, but the minimal value is

$$Q(A^{-1}b) = -\frac{1}{2}b^\top A^{-1}b + c.$$

Thus when the energy function $Q(x)$ of a system is given by a quadratic function

$$Q(x) = \frac{1}{2}x^\top Ax - x^\top b,$$

where A is symmetric positive definite, finding the global minimum of $Q(x)$ is equivalent to solving the linear system $Ax = b$. Sometimes, it is useful to recast a linear problem $Ax = b$ as a variational problem (finding the minimum of some energy function). However, very often, a minimization problem comes with extra constraints that must be satisfied for all admissible solutions.

Example 42.1. For instance, we may want to minimize the quadratic function

$$Q(x_1, x_2) = \frac{1}{2}(x_1^2 + x_2^2)$$

subject to the constraint

$$2x_1 - x_2 = 5.$$

The solution for which $Q(x_1, x_2)$ is minimum is no longer $(x_1, x_2) = (0, 0)$, but instead, $(x_1, x_2) = (2, -1)$, as will be shown later.

Geometrically, the graph of the function defined by $z = Q(x_1, x_2)$ in \mathbb{R}^3 is a paraboloid of revolution P with axis of revolution Oz . The constraint

$$2x_1 - x_2 = 5$$

corresponds to the vertical plane H parallel to the z -axis and containing the line of equation $2x_1 - x_2 = 5$ in the xy -plane. Thus, as illustrated by Figure 42.1, the constrained minimum of Q is located on the parabola that is the intersection of the paraboloid P with the plane H .

A nice way to solve constrained minimization problems of the above kind is to use the method of *Lagrange multipliers* discussed in Section 40.1. But first let us define precisely what kind of minimization problems we intend to solve.

Definition 42.3. The *quadratic constrained minimization problem* consists in minimizing a quadratic function

$$Q(x) = \frac{1}{2}x^\top A^{-1}x - b^\top x$$

subject to the linear constraints

$$B^\top x = f,$$

where A^{-1} is an $m \times m$ symmetric positive definite matrix, B is an $m \times n$ matrix of rank n (so that $m \geq n$), and where $b, x \in \mathbb{R}^m$ (viewed as column vectors), and $f \in \mathbb{R}^n$ (viewed as a column vector).

The reason for using A^{-1} instead of A is that the constrained minimization problem has an interpretation as a set of equilibrium equations in which the matrix that arises naturally is A (see Strang [169]). Since A and A^{-1} are both symmetric positive definite, this doesn't make any difference, but it seems preferable to stick to Strang's notation.

In Example 42.1 we have $m = 2$, $n = 1$,

$$A = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = I_2, \quad b = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \quad B = \begin{pmatrix} 2 \\ -1 \end{pmatrix}, \quad f = 5.$$

As explained in Section 40.1, the method of Lagrange multipliers consists in incorporating the n constraints $B^\top x = f$ into the quadratic function $Q(x)$, by introducing extra variables

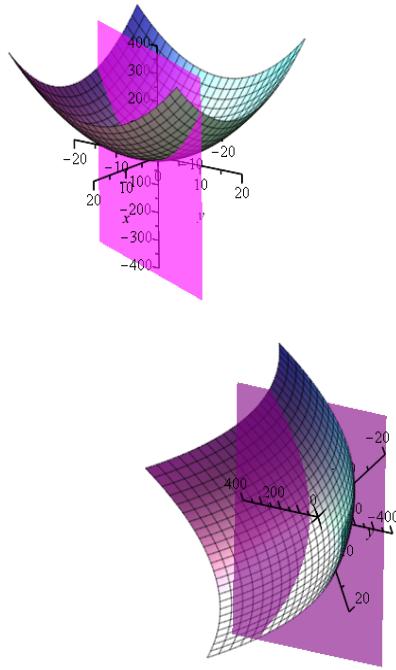

Figure 42.1: Two views of the constrained optimization problem $Q(x_1, x_2) = \frac{1}{2}(x_1^2 + x_2^2)$ subject to the constraint $2x_1 - x_2 = 5$. The minimum $(x_1, x_2) = (2, -1)$ is the vertex of the parabolic curve formed by the intersection of the magenta planar constraint with the bowl shaped surface.

$\lambda = (\lambda_1, \dots, \lambda_n)$ called *Lagrange multipliers*, one for each constraint. We form the *Lagrangian*

$$L(x, \lambda) = Q(x) + \lambda^\top (B^\top x - f) = \frac{1}{2}x^\top A^{-1}x - (b - B\lambda)^\top x - \lambda^\top f.$$

We know from Theorem 40.2 that a necessary condition for our constrained optimization problem to have a solution is that $\nabla L(x, \lambda) = 0$. Since

$$\begin{aligned}\frac{\partial L}{\partial x}(x, \lambda) &= A^{-1}x - (b - B\lambda) \\ \frac{\partial L}{\partial \lambda}(x, \lambda) &= B^\top x - f,\end{aligned}$$

we obtain the system of linear equations

$$\begin{aligned}A^{-1}x + B\lambda &= b, \\ B^\top x &= f,\end{aligned}$$

which can be written in matrix form as

$$\begin{pmatrix} A^{-1} & B \\ B^\top & 0 \end{pmatrix} \begin{pmatrix} x \\ \lambda \end{pmatrix} = \begin{pmatrix} b \\ f \end{pmatrix}.$$

We shall prove in Proposition 42.3 below that our constrained minimization problem has a unique solution actually given by the above system.

Note that the matrix of this system is symmetric. We solve it as follows. Eliminating x from the first equation

$$A^{-1}x + B\lambda = b,$$

we get

$$x = A(b - B\lambda),$$

and substituting into the second equation, we get

$$B^\top A(b - B\lambda) = f,$$

that is,

$$B^\top AB\lambda = B^\top Ab - f.$$

However, by a previous remark, since A is symmetric positive definite and the columns of B are linearly independent, $B^\top AB$ is symmetric positive definite, and thus invertible. Thus we obtain the solution

$$\lambda = (B^\top AB)^{-1}(B^\top Ab - f), \quad x = A(b - B\lambda).$$

Note that this way of solving the system requires solving for the Lagrange multipliers first.

Letting $e = b - B\lambda$, we also note that the system

$$\begin{pmatrix} A^{-1} & B \\ B^\top & 0 \end{pmatrix} \begin{pmatrix} x \\ \lambda \end{pmatrix} = \begin{pmatrix} b \\ f \end{pmatrix}$$

is equivalent to the system

$$\begin{aligned} e &= b - B\lambda, \\ x &= Ae, \\ B^\top x &= f. \end{aligned}$$

The latter system is called the *equilibrium equations* by Strang [169]. Indeed, Strang shows that the equilibrium equations of many physical systems can be put in the above form. This includes spring-mass systems, electrical networks and trusses, which are structures built from elastic bars. In each case, x , e , b , A , λ , f , and $K = B^\top AB$ have a physical interpretation. The matrix $K = B^\top AB$ is usually called the *stiffness matrix*. Again, the reader is referred to Strang [169].

In order to prove that our constrained minimization problem has a unique solution, we proceed to prove that the constrained minimization of $Q(x)$ subject to $B^\top x = f$ is equivalent to the unconstrained maximization of another function $-G(\lambda)$. We get $G(\lambda)$ by minimizing the Lagrangian $L(x, \lambda)$ treated as a function of x alone. The function $-G(\lambda)$ is the *dual function* of the Lagrangian $L(x, \lambda)$. Here we are encountering a special case of the notion of dual function defined in Section 50.7.

Since A^{-1} is symmetric positive definite and

$$L(x, \lambda) = \frac{1}{2}x^\top A^{-1}x - (b - B\lambda)^\top x - \lambda^\top f,$$

by Proposition 42.2 the global minimum (with respect to x) of $L(x, \lambda)$ is obtained for the solution x of

$$A^{-1}x = b - B\lambda,$$

that is, when

$$x = A(b - B\lambda),$$

and the minimum of $L(x, \lambda)$ is

$$\min_x L(x, \lambda) = -\frac{1}{2}(B\lambda - b)^\top A(B\lambda - b) - \lambda^\top f.$$

Letting

$$G(\lambda) = \frac{1}{2}(B\lambda - b)^\top A(B\lambda - b) + \lambda^\top f,$$

we will show in Proposition 42.3 that the solution of the constrained minimization of $Q(x)$ subject to $B^\top x = f$ is equivalent to the unconstrained maximization of $-G(\lambda)$. This is a special case of the duality discussed in Section 50.7.

Of course, since we minimized $L(x, \lambda)$ with respect to x , we have

$$L(x, \lambda) \geq -G(\lambda)$$

for all x and all λ . However, when the constraint $B^\top x = f$ holds, $L(x, \lambda) = Q(x)$, and thus for any admissible x , which means that $B^\top x = f$, we have

$$\min_x Q(x) \geq \max_\lambda -G(\lambda).$$

In order to prove that the unique minimum of the constrained problem $Q(x)$ subject to $B^\top x = f$ is the unique maximum of $-G(\lambda)$, we compute $Q(x) + G(\lambda)$.

Proposition 42.3. *The quadratic constrained minimization problem of Definition 42.3 has a unique solution (x, λ) given by the system*

$$\begin{pmatrix} A^{-1} & B \\ B^\top & 0 \end{pmatrix} \begin{pmatrix} x \\ \lambda \end{pmatrix} = \begin{pmatrix} b \\ f \end{pmatrix}.$$

Furthermore, the component λ of the above solution is the unique value for which $-G(\lambda)$ is maximum.

Proof. As we suggested earlier, let us compute $Q(x) + G(\lambda)$, assuming that the constraint $B^\top x = f$ holds. Eliminating f , since $b^\top x = x^\top b$ and $\lambda^\top B^\top x = x^\top B\lambda$, we get

$$\begin{aligned} Q(x) + G(\lambda) &= \frac{1}{2}x^\top A^{-1}x - b^\top x + \frac{1}{2}(B\lambda - b)^\top A(B\lambda - b) + \lambda^\top f \\ &= \frac{1}{2}(A^{-1}x + B\lambda - b)^\top A(A^{-1}x + B\lambda - b). \end{aligned}$$

Since A is positive definite, the last expression is nonnegative. In fact, it is null iff

$$A^{-1}x + B\lambda - b = 0,$$

that is,

$$A^{-1}x + B\lambda = b.$$

But then the unique constrained minimum of $Q(x)$ subject to $B^\top x = f$ is equal to the unique maximum of $-G(\lambda)$ exactly when $B^\top x = f$ and $A^{-1}x + B\lambda = b$, which proves the proposition. \square

We can confirm that the maximum of $-G(\lambda)$, or equivalently the minimum of

$$G(\lambda) = \frac{1}{2}(B\lambda - b)^\top A(B\lambda - b) + \lambda^\top f,$$

corresponds to value of λ obtained by solving the system

$$\begin{pmatrix} A^{-1} & B \\ B^\top & 0 \end{pmatrix} \begin{pmatrix} x \\ \lambda \end{pmatrix} = \begin{pmatrix} b \\ f \end{pmatrix}.$$

Indeed, since

$$G(\lambda) = \frac{1}{2}\lambda^\top B^\top AB\lambda - \lambda^\top B^\top Ab + \lambda^\top f + \frac{1}{2}b^\top b,$$

and $B^\top AB$ is symmetric positive definite, by Proposition 42.2, the global minimum of $G(\lambda)$ is obtained when

$$B^\top AB\lambda - B^\top Ab + f = 0,$$

that is, $\lambda = (B^\top AB)^{-1}(B^\top Ab - f)$, as we found earlier.

Remarks:

- (1) There is a form of duality going on in this situation. The constrained minimization of $Q(x)$ subject to $B^\top x = f$ is called the *primal problem*, and the unconstrained maximization of $-G(\lambda)$ is called the *dual problem*. Duality is the fact stated slightly loosely as

$$\min_x Q(x) = \max_\lambda -G(\lambda).$$

A general treatment of duality in constrained minimization problems is given in Section 50.7.

Recalling that $e = b - B\lambda$, since

$$G(\lambda) = \frac{1}{2}(B\lambda - b)^\top A(B\lambda - b) + \lambda^\top f,$$

we can also write

$$G(\lambda) = \frac{1}{2}e^\top Ae + \lambda^\top f.$$

This expression often represents the total potential energy of a system. Again, the optimal solution is the one that minimizes the potential energy (and thus maximizes $-G(\lambda)$).

- (2) It is immediately verified that the equations of Proposition 42.3 are equivalent to the equations stating that the partial derivatives of the Lagrangian $L(x, \lambda)$ are null:

$$\begin{aligned}\frac{\partial L}{\partial x_i} &= 0, \quad i = 1, \dots, m, \\ \frac{\partial L}{\partial \lambda_j} &= 0, \quad j = 1, \dots, n.\end{aligned}$$

Thus, the constrained minimum of $Q(x)$ subject to $B^\top x = f$ is an extremum of the Lagrangian $L(x, \lambda)$. As we showed in Proposition 42.3, this extremum corresponds to simultaneously minimizing $L(x, \lambda)$ with respect to x and maximizing $L(x, \lambda)$ with respect to λ . Geometrically, such a point is a *saddle point* for $L(x, \lambda)$. Saddle points are discussed in Section 50.7.

- (3) The Lagrange multipliers sometimes have a natural physical meaning. For example, in the spring-mass system they correspond to node displacements. In some general sense, Lagrange multipliers are correction terms needed to satisfy equilibrium equations and the price paid for the constraints. For more details, see Strang [169].

Going back to the constrained minimization of $Q(x_1, x_2) = \frac{1}{2}(x_1^2 + x_2^2)$ subject to

$$2x_1 - x_2 = 5,$$

the Lagrangian is

$$L(x_1, x_2, \lambda) = \frac{1}{2}(x_1^2 + x_2^2) + \lambda(2x_1 - x_2 - 5),$$

and the equations stating that the Lagrangian has a saddle point are

$$\begin{aligned}x_1 + 2\lambda &= 0, \\ x_2 - \lambda &= 0, \\ 2x_1 - x_2 - 5 &= 0.\end{aligned}$$

We obtain the solution $(x_1, x_2, \lambda) = (2, -1, -1)$.

The use of Lagrange multipliers in optimization and variational problems is discussed extensively in Chapter 50.

Least squares methods and Lagrange multipliers are used to tackle many problems in computer graphics and computer vision; see Trucco and Verri [178], Metaxas [124], Jain, Katsuri, and Schunck [100], Faugeras [59], and Foley, van Dam, Feiner, and Hughes [63].

42.2 Quadratic Optimization: The General Case

In this section we complete the study initiated in Section 42.1 and give necessary and sufficient conditions for the quadratic function $\frac{1}{2}x^\top Ax - x^\top b$ to have a global minimum. We begin with the following simple fact:

Proposition 42.4. *If A is an invertible symmetric matrix, then the function*

$$f(x) = \frac{1}{2}x^\top Ax - x^\top b$$

has a minimum value iff $A \succeq 0$, in which case this optimal value is obtained for a unique value of x , namely $x^ = A^{-1}b$, and with*

$$f(A^{-1}b) = -\frac{1}{2}b^\top A^{-1}b.$$

Proof. Observe that

$$\frac{1}{2}(x - A^{-1}b)^\top A(x - A^{-1}b) = \frac{1}{2}x^\top Ax - x^\top b + \frac{1}{2}b^\top A^{-1}b.$$

Thus,

$$f(x) = \frac{1}{2}x^\top Ax - x^\top b = \frac{1}{2}(x - A^{-1}b)^\top A(x - A^{-1}b) - \frac{1}{2}b^\top A^{-1}b.$$

If A has some negative eigenvalue, say $-\lambda$ (with $\lambda > 0$), if we pick any eigenvector u of A associated with λ , then for any $\alpha \in \mathbb{R}$ with $\alpha \neq 0$, if we let $x = \alpha u + A^{-1}b$, then since $Au = -\lambda u$, we get

$$\begin{aligned} f(x) &= \frac{1}{2}(x - A^{-1}b)^\top A(x - A^{-1}b) - \frac{1}{2}b^\top A^{-1}b \\ &= \frac{1}{2}\alpha u^\top A\alpha u - \frac{1}{2}b^\top A^{-1}b \\ &= -\frac{1}{2}\alpha^2 \lambda \|u\|_2^2 - \frac{1}{2}b^\top A^{-1}b, \end{aligned}$$

and since α can be made as large as we want and $\lambda > 0$, we see that f has no minimum. Consequently, in order for f to have a minimum, we must have $A \succeq 0$. If $A \succeq 0$, since A is invertible, it is positive definite, so $(x - A^{-1}b)^\top A(x - A^{-1}b) > 0$ iff $x - A^{-1}b \neq 0$, and it is clear that the minimum value of f is achieved when $x - A^{-1}b = 0$, that is, $x = A^{-1}b$. \square

Let us now consider the case of an arbitrary symmetric matrix A .

Proposition 42.5. *If A is an $n \times n$ symmetric matrix, then the function*

$$f(x) = \frac{1}{2}x^\top Ax - x^\top b$$

has a minimum value iff $A \succeq 0$ and $(I - AA^+)^{-1}b = 0$, in which case this minimum value is

$$p^* = -\frac{1}{2}b^\top A^+b.$$

Furthermore, if A is diagonalized as $A = U^\top \Sigma U$ (with U orthogonal), then the optimal value is achieved by all $x \in \mathbb{R}^n$ of the form

$$x = A^+b + U^\top \begin{pmatrix} 0 \\ z \end{pmatrix},$$

for any $z \in \mathbb{R}^{n-r}$, where r is the rank of A .

Proof. The case that A is invertible is taken care of by Proposition 42.4, so we may assume that A is singular. If A has rank $r < n$, then we can diagonalize A as

$$A = U^\top \begin{pmatrix} \Sigma_r & 0 \\ 0 & 0 \end{pmatrix} U,$$

where U is an orthogonal matrix and where Σ_r is an $r \times r$ diagonal invertible matrix. Then we have

$$\begin{aligned} f(x) &= \frac{1}{2}x^\top U^\top \begin{pmatrix} \Sigma_r & 0 \\ 0 & 0 \end{pmatrix} Ux - x^\top U^\top Ub \\ &= \frac{1}{2}(Ux)^\top \begin{pmatrix} \Sigma_r & 0 \\ 0 & 0 \end{pmatrix} Ux - (Ux)^\top Ub. \end{aligned}$$

If we write

$$Ux = \begin{pmatrix} y \\ z \end{pmatrix} \quad \text{and} \quad Ub = \begin{pmatrix} c \\ d \end{pmatrix},$$

with $y, c \in \mathbb{R}^r$ and $z, d \in \mathbb{R}^{n-r}$, we get

$$\begin{aligned} f(x) &= \frac{1}{2}(Ux)^\top \begin{pmatrix} \Sigma_r & 0 \\ 0 & 0 \end{pmatrix} Ux - (Ux)^\top Ub \\ &= \frac{1}{2}(y^\top z^\top) \begin{pmatrix} \Sigma_r & 0 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} y \\ z \end{pmatrix} - (y^\top z^\top) \begin{pmatrix} c \\ d \end{pmatrix} \\ &= \frac{1}{2}y^\top \Sigma_r y - y^\top c - z^\top d. \end{aligned}$$

For $y = 0$, we get

$$f(x) = -z^\top d,$$

so if $d \neq 0$, the function f has no minimum. Therefore, if f has a minimum, then $d = 0$. However, $d = 0$ means that

$$Ub = \begin{pmatrix} c \\ 0 \end{pmatrix},$$

and we know from Proposition 23.5 that b is in the range of A (here, U is V^\top), which is equivalent to $(I - AA^\top)b = 0$. If $d = 0$, then

$$f(x) = \frac{1}{2}y^\top \Sigma_r y - y^\top c.$$

Consider the function $g: \mathbb{R}^r \rightarrow \mathbb{R}$ given by

$$g(y) = \frac{1}{2}y^\top \Sigma_r y - y^\top c, \quad y \in \mathbb{R}^r.$$

Since

$$\begin{pmatrix} y \\ z \end{pmatrix} = U^\top x$$

and U^\top is invertible (with inverse U), when x ranges over \mathbb{R}^n , y ranges over the whole of \mathbb{R}^r , and since $f(x) = g(y)$, the function f has a minimum iff g has a minimum. Since Σ_r is invertible, by Proposition 42.4, the function g has a minimum iff $\Sigma_r \succeq 0$, which is equivalent to $A \succeq 0$.

Therefore, we have proven that if f has a minimum, then $(I - AA^\top)b = 0$ and $A \succeq 0$. Conversely, if $(I - AA^\top)b = 0$, then

$$\begin{aligned} \left(\begin{pmatrix} I_r & 0 \\ 0 & I_{n-r} \end{pmatrix} - U^\top \begin{pmatrix} \Sigma_r & 0 \\ 0 & 0 \end{pmatrix} U U^\top \begin{pmatrix} \Sigma_r^{-1} & 0 \\ 0 & 0 \end{pmatrix} U \right) b &= \left(\begin{pmatrix} I_r & 0 \\ 0 & I_{n-r} \end{pmatrix} - U^\top \begin{pmatrix} I_r & 0 \\ 0 & 0 \end{pmatrix} U \right) b \\ &= U^\top \begin{pmatrix} 0 & 0 \\ 0 & I_{n-r} \end{pmatrix} U b = 0, \end{aligned}$$

which implies that if

$$Ub = \begin{pmatrix} c \\ d \end{pmatrix},$$

then $d = 0$, so as above

$$f(x) = g(y) = \frac{1}{2}y^\top \Sigma_r y - y^\top c,$$

and because $A \succeq 0$, we also have $\Sigma_r \succeq 0$, so g and f have a minimum.

When the above conditions hold, since

$$A = U^\top \begin{pmatrix} \Sigma_r & 0 \\ 0 & 0 \end{pmatrix} U$$

is positive semidefinite, the pseudo-inverse A^+ of A is given by

$$A^+ = U^\top \begin{pmatrix} \Sigma_r^{-1} & 0 \\ 0 & 0 \end{pmatrix} U,$$

and since

$$f(x) = g(y) = \frac{1}{2} y^\top \Sigma_r y - y^\top c,$$

by Proposition 42.4 the minimum of g is achieved iff $y^* = \Sigma_r^{-1}c$. Since $f(x)$ is independent of z , we can choose $z = 0$, and since $d = 0$, for x^* given by

$$Ux^* = \begin{pmatrix} \Sigma_r^{-1}c \\ 0 \end{pmatrix} \quad \text{and} \quad Ub = \begin{pmatrix} c \\ 0 \end{pmatrix},$$

we deduce that

$$x^* = U^\top \begin{pmatrix} \Sigma_r^{-1}c \\ 0 \end{pmatrix} = U^\top \begin{pmatrix} \Sigma_r^{-1} & 0 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} c \\ 0 \end{pmatrix} = U^\top \begin{pmatrix} \Sigma_r^{-1} & 0 \\ 0 & 0 \end{pmatrix} Ub = A^+b, \quad (*)$$

and the minimum value of f is

$$f(x^*) = \frac{1}{2}(A^+b)^\top AA^+b - b^\top A^+b = \frac{1}{2}b^\top A^+AA^+b - b^\top A^+b = -\frac{1}{2}b^\top A^+b,$$

since A^+ is symmetric and $A^+AA^+ = A^+$. For any $x \in \mathbb{R}^n$ of the form

$$x = A^+b + U^\top \begin{pmatrix} 0 \\ z \end{pmatrix}, \quad z \in \mathbb{R}^{n-r},$$

since

$$x = A^+b + U^\top \begin{pmatrix} 0 \\ z \end{pmatrix} = U^\top \begin{pmatrix} \Sigma_r^{-1}c \\ 0 \end{pmatrix} + U^\top \begin{pmatrix} 0 \\ z \end{pmatrix} = U^\top \begin{pmatrix} \Sigma_r^{-1}c \\ z \end{pmatrix},$$

and since $f(x)$ is independent of z (because $f(x) = g(y)$), we have

$$f(x) = f(x^*) = -\frac{1}{2}b^\top A^+b. \quad \square$$

The problem of minimizing the function

$$f(x) = \frac{1}{2}x^\top Ax - x^\top b$$

in the case where we add either linear constraints of the form $C^\top x = 0$ or affine constraints of the form $C^\top x = t$ (where $t \in \mathbb{R}^m$ and $t \neq 0$) where C is an $n \times m$ matrix can be reduced to the unconstrained case using a QR -decomposition of C . Let us show how to do this for linear constraints of the form $C^\top x = 0$.

If we use a QR decomposition of C , by permuting the columns of C to make sure that the first r columns of C are linearly independent (where $r = \text{rank}(C)$), we may assume that

$$C = Q^\top \begin{pmatrix} R & S \\ 0 & 0 \end{pmatrix} \Pi,$$

where Q is an $n \times n$ orthogonal matrix, R is an $r \times r$ invertible upper triangular matrix, S is an $r \times (m - r)$ matrix, and Π is a permutation matrix (C has rank r). Then if we let

$$x = Q^\top \begin{pmatrix} y \\ z \end{pmatrix},$$

where $y \in \mathbb{R}^r$ and $z \in \mathbb{R}^{n-r}$, then $C^\top x = 0$ becomes

$$C^\top x = \Pi^\top \begin{pmatrix} R^\top & 0 \\ S^\top & 0 \end{pmatrix} Q x = \Pi^\top \begin{pmatrix} R^\top & 0 \\ S^\top & 0 \end{pmatrix} \begin{pmatrix} y \\ z \end{pmatrix} = 0,$$

which implies $y = 0$, and every solution of $C^\top x = 0$ is of the form

$$x = Q^\top \begin{pmatrix} 0 \\ z \end{pmatrix}.$$

Our original problem becomes

$$\begin{aligned} \text{minimize} \quad & \frac{1}{2} (y^\top z^\top) Q A Q^\top \begin{pmatrix} y \\ z \end{pmatrix} + (y^\top z^\top) Q b \\ \text{subject to} \quad & y = 0, \quad y \in \mathbb{R}^r, \quad z \in \mathbb{R}^{n-r}. \end{aligned}$$

Thus, the constraint $C^\top x = 0$ has been simplified to $y = 0$, and if we write

$$Q A Q^\top = \begin{pmatrix} G_{11} & G_{12} \\ G_{21} & G_{22} \end{pmatrix},$$

where G_{11} is an $r \times r$ matrix and G_{22} is an $(n - r) \times (n - r)$ matrix and

$$Q b = \begin{pmatrix} b_1 \\ b_2 \end{pmatrix}, \quad b_1 \in \mathbb{R}^r, \quad b_2 \in \mathbb{R}^{n-r},$$

our problem becomes

$$\text{minimize} \quad \frac{1}{2} z^\top G_{22} z + z^\top b_2, \quad z \in \mathbb{R}^{n-r},$$

the problem solved in Proposition 42.5.

Constraints of the form $C^\top x = t$ (where $t \neq 0$) can be handled in a similar fashion. In this case, we may assume that C is an $n \times m$ matrix with full rank (so that $m \leq n$) and $t \in \mathbb{R}^m$. Then we use a QR -decomposition of the form

$$C = P \begin{pmatrix} R \\ 0 \end{pmatrix},$$

where P is an orthogonal $n \times n$ matrix and R is an $m \times m$ invertible upper triangular matrix. If we write

$$x = P \begin{pmatrix} y \\ z \end{pmatrix},$$

where $y \in \mathbb{R}^m$ and $z \in \mathbb{R}^{n-m}$, the equation $C^\top x = t$ becomes

$$(R^\top 0)P^\top x = t,$$

that is,

$$(R^\top 0) \begin{pmatrix} y \\ z \end{pmatrix} = t,$$

which yields

$$R^\top y = t.$$

Since R is invertible, we get $y = (R^\top)^{-1}t$, and then it is easy to see that our original problem reduces to an unconstrained problem in terms of the matrix $P^\top AP$; the details are left as an exercise.

42.3 Maximizing a Quadratic Function on the Unit Sphere

In this section we discuss various quadratic optimization problems mostly arising from computer vision (image segmentation and contour grouping). These problems can be reduced to the following basic optimization problem: given an $n \times n$ real symmetric matrix A

$$\begin{aligned} & \text{maximize} && x^\top Ax \\ & \text{subject to} && x^\top x = 1, \quad x \in \mathbb{R}^n. \end{aligned}$$

In view of Proposition 23.10, the maximum value of $x^\top Ax$ on the unit sphere is equal to the largest eigenvalue λ_1 of the matrix A , and it is achieved for any unit eigenvector u_1 associated with λ_1 . Similarly, the minimum value of $x^\top Ax$ on the unit sphere is equal to the smallest eigenvalue λ_n of the matrix A , and it is achieved for any unit eigenvector u_n associated with λ_n .

A variant of the above problem often encountered in computer vision consists in minimizing $x^\top Ax$ on the ellipsoid given by an equation of the form

$$x^\top Bx = 1,$$

where B is a symmetric positive definite matrix. Since B is positive definite, it can be diagonalized as

$$B = QDQ^\top,$$

where Q is an orthogonal matrix and D is a diagonal matrix,

$$D = \text{diag}(d_1, \dots, d_n),$$

with $d_i > 0$, for $i = 1, \dots, n$. If we define the matrices $B^{1/2}$ and $B^{-1/2}$ by

$$B^{1/2} = Q \text{diag}(\sqrt{d_1}, \dots, \sqrt{d_n}) Q^\top$$

and

$$B^{-1/2} = Q \text{diag}\left(1/\sqrt{d_1}, \dots, 1/\sqrt{d_n}\right) Q^\top,$$

it is clear that these matrices are symmetric, that $B^{-1/2}BB^{-1/2} = I$, and that $B^{1/2}$ and $B^{-1/2}$ are mutual inverses. Then if we make the change of variable

$$x = B^{-1/2}y,$$

the equation $x^\top Bx = 1$ becomes $y^\top y = 1$, and the optimization problem

$$\begin{aligned} &\text{minimize} && x^\top Ax \\ &\text{subject to} && x^\top Bx = 1, \quad x \in \mathbb{R}^n, \end{aligned}$$

is equivalent to the problem

$$\begin{aligned} &\text{minimize} && y^\top B^{-1/2}AB^{-1/2}y \\ &\text{subject to} && y^\top y = 1, \quad y \in \mathbb{R}^n, \end{aligned}$$

where $y = B^{1/2}x$ and $B^{-1/2}AB^{-1/2}$ are symmetric.

The complex version of our basic optimization problem in which A is a Hermitian matrix also arises in computer vision. Namely, given an $n \times n$ complex Hermitian matrix A ,

$$\begin{aligned} &\text{maximize} && x^*Ax \\ &\text{subject to} && x^*x = 1, \quad x \in \mathbb{C}^n. \end{aligned}$$

Again by Proposition 23.10, the maximum value of x^*Ax on the unit sphere is equal to the largest eigenvalue λ_1 of the matrix A , and it is achieved for any unit eigenvector u_1 associated with λ_1 .

Remark: It is worth pointing out that if A is a *skew-Hermitian* matrix, that is, if $A^* = -A$, then x^*Ax is *pure imaginary or zero*.

Indeed, since $z = x^*Ax$ is a scalar, we have $z^* = \bar{z}$ (the conjugate of z), so we have

$$\overline{x^*Ax} = (x^*Ax)^* = x^*A^*x = -x^*Ax,$$

so $\overline{x^*Ax} + x^*Ax = 2\text{Re}(x^*Ax) = 0$, which means that x^*Ax is pure imaginary or zero.

In particular, if A is a real matrix and if A is *skew-symmetric*, then

$$x^\top Ax = 0.$$

Thus, for any real matrix (symmetric or not),

$$x^\top Ax = x^\top H(A)x,$$

where $H(A) = (A + A^\top)/2$, the symmetric part of A .

There are situations in which it is necessary to add linear constraints to the problem of maximizing a quadratic function on the sphere. This problem was completely solved by Golub [78] (1973). The problem is the following: given an $n \times n$ real symmetric matrix A and an $n \times p$ matrix C ,

$$\begin{aligned} & \text{minimize} && x^\top Ax \\ & \text{subject to} && x^\top x = 1, C^\top x = 0, x \in \mathbb{R}^n. \end{aligned}$$

As in Section 42.2, Golub shows that the linear constraint $C^\top x = 0$ can be eliminated as follows: if we use a QR decomposition of C , by permuting the columns, we may assume that

$$C = Q^\top \begin{pmatrix} R & S \\ 0 & 0 \end{pmatrix} \Pi,$$

where Q is an orthogonal $n \times n$ matrix, R is an $r \times r$ invertible upper triangular matrix, and S is an $r \times (p - r)$ matrix (assuming C has rank r). If we let

$$x = Q^\top \begin{pmatrix} y \\ z \end{pmatrix},$$

where $y \in \mathbb{R}^r$ and $z \in \mathbb{R}^{n-r}$, then $C^\top x = 0$ becomes

$$\Pi^\top \begin{pmatrix} R^\top & 0 \\ S^\top & 0 \end{pmatrix} Qx = \Pi^\top \begin{pmatrix} R^\top & 0 \\ S^\top & 0 \end{pmatrix} \begin{pmatrix} y \\ z \end{pmatrix} = 0,$$

which implies $y = 0$, and every solution of $C^\top x = 0$ is of the form

$$x = Q^\top \begin{pmatrix} 0 \\ z \end{pmatrix}.$$

Our original problem becomes

$$\begin{aligned} & \text{minimize} && (y^\top z^\top) Q A Q^\top \begin{pmatrix} y \\ z \end{pmatrix} \\ & \text{subject to} && z^\top z = 1, z \in \mathbb{R}^{n-r}, \\ & && y = 0, y \in \mathbb{R}^r. \end{aligned}$$

Thus the constraint $C^\top x = 0$ has been simplified to $y = 0$, and if we write

$$QAQ^\top = \begin{pmatrix} G_{11} & G_{12} \\ G_{12}^\top & G_{22} \end{pmatrix},$$

our problem becomes

$$\begin{aligned} &\text{minimize} && z^\top G_{22} z \\ &\text{subject to} && z^\top z = 1, z \in \mathbb{R}^{n-r}, \end{aligned}$$

a standard eigenvalue problem.

Remark: There is a way of finding the eigenvalues of G_{22} which does not require the QR -factorization of C . Observe that if we let

$$J = \begin{pmatrix} 0 & 0 \\ 0 & I_{n-r} \end{pmatrix},$$

then

$$JQAQ^\top J = \begin{pmatrix} 0 & 0 \\ 0 & G_{22} \end{pmatrix},$$

and if we set

$$P = Q^\top J Q,$$

then

$$PAP = Q^\top JQAQ^\top J Q.$$

Now, $Q^\top JQAQ^\top J Q$ and $JQAQ^\top J$ have the same eigenvalues, so PAP and $JQAQ^\top J$ also have the same eigenvalues. It follows that the solutions of our optimization problem are among the eigenvalues of $K = PAP$, and at least r of those are 0. Using the fact that CC^+ is the projection onto the range of C , where C^+ is the pseudo-inverse of C , it can also be shown that

$$P = I - CC^+,$$

the projection onto the kernel of C^\top . So P can be computed directly in terms of C . In particular, when $n \geq p$ and C has full rank (the columns of C are linearly independent), then we know that $C^+ = (C^\top C)^{-1}C^\top$ and

$$P = I - C(C^\top C)^{-1}C^\top.$$

This fact is used by Cour and Shi [42] and implicitly by Yu and Shi [192].

The problem of adding affine constraints of the form $N^\top x = t$, where $t \neq 0$, also comes up in practice. At first glance, this problem may not seem harder than the linear problem in which $t = 0$, but it is. This problem was extensively studied in a paper by Gander, Golub, and von Matt [75] (1989).

Gander, Golub, and von Matt consider the following problem: Given an $(n+m) \times (n+m)$ real symmetric matrix A (with $n > 0$), an $(n+m) \times m$ matrix N with full rank, and a nonzero vector $t \in \mathbb{R}^m$ with $\|(N^\top)^+ t\| < 1$ (where $(N^\top)^+$ denotes the pseudo-inverse of N^\top),

$$\begin{aligned} \text{minimize} \quad & x^\top A x \\ \text{subject to} \quad & x^\top x = 1, \quad N^\top x = t, \quad x \in \mathbb{R}^{n+m}. \end{aligned}$$

The condition $\|(N^\top)^+ t\| < 1$ ensures that the problem has a solution and is not trivial. The authors begin by proving that the affine constraint $N^\top x = t$ can be eliminated. One way to do so is to use a QR decomposition of N . If

$$N = P \begin{pmatrix} R \\ 0 \end{pmatrix},$$

where P is an orthogonal $(n+m) \times (n+m)$ matrix and R is an $m \times m$ invertible upper triangular matrix, then if we observe that

$$\begin{aligned} x^\top A x &= x^\top P P^\top A P P^\top x, \\ N^\top x &= (R^\top 0) P^\top x = t, \\ x^\top x &= x^\top P P^\top x = 1, \end{aligned}$$

and if we write

$$P^\top A P = \begin{pmatrix} B & \Gamma^\top \\ \Gamma & C \end{pmatrix},$$

where B is an $m \times m$ symmetric matrix, C is an $n \times n$ symmetric matrix, Γ is an $m \times n$ matrix, and

$$P^\top x = \begin{pmatrix} y \\ z \end{pmatrix},$$

with $y \in \mathbb{R}^m$ and $z \in \mathbb{R}^n$, we then get

$$\begin{aligned} x^\top A x &= y^\top B y + 2z^\top \Gamma y + z^\top C z, \\ R^\top y &= t, \\ y^\top y + z^\top z &= 1. \end{aligned}$$

Thus

$$y = (R^\top)^{-1} t,$$

and if we write

$$s^2 = 1 - y^\top y > 0$$

and

$$b = \Gamma y,$$

we get the simplified problem

$$\begin{aligned} & \text{minimize} && z^\top Cz + 2z^\top b \\ & \text{subject to} && z^\top z = s^2, \quad z \in \mathbb{R}^m. \end{aligned}$$

Unfortunately, if $b \neq 0$, Proposition 23.10 is no longer applicable. It is still possible to find the minimum of the function $z^\top Cz + 2z^\top b$ using Lagrange multipliers, but such a solution is too involved to be presented here. Interested readers will find a thorough discussion in Gander, Golub, and von Matt [75].

42.4 Summary

The main concepts and results of this chapter are listed below:

- Quadratic optimization problems; *quadratic functions*.
- Symmetric *positive definite* and *positive semidefinite* matrices.
- The *positive semidefinite cone ordering*.
- Existence of a global minimum when A is symmetric positive definite.
- Constrained quadratic optimization problems.
- *Lagrange multipliers*; *Lagrangian*.
- *Primal* and *dual* problems.
- Quadratic optimization problems: the case of a symmetric invertible matrix A .
- Quadratic optimization problems: the general case of a symmetric matrix A .
- Adding linear constraints of the form $C^\top x = 0$.
- Adding affine constraints of the form $C^\top x = t$, with $t \neq 0$.
- Maximizing a quadratic function over the unit sphere.
- Maximizing a quadratic function over an ellipsoid.
- Maximizing a Hermitian quadratic form.
- Adding linear constraints of the form $C^\top x = 0$.
- Adding affine constraints of the form $N^\top x = t$, with $t \neq 0$.

42.5 Problems

Problem 42.1. Prove that the relation

$$A \succeq B$$

between any two $n \times n$ matrices (symmetric or not) iff $A - B$ is symmetric positive semidefinite is indeed a partial order.

Problem 42.2. (1) Prove that if A is symmetric positive definite, then so is A^{-1} .

(2) Prove that if C is a symmetric positive definite $m \times m$ matrix and A is an $m \times n$ matrix of rank n (and so $m \geq n$ and the map $x \mapsto Ax$ is injective), then $A^\top CA$ is symmetric positive definite.

Problem 42.3. Find the minimum of the function

$$Q(x_1, x_2) = \frac{1}{2}(2x_1^2 + x_2^2)$$

subject to the constraint

$$x_1 - x_2 = 3.$$

Problem 42.4. Consider the problem of minimizing the function

$$f(x) = \frac{1}{2}x^\top Ax - x^\top b$$

in the case where we add an affine constraint of the form $C^\top x = t$, with $t \in \mathbb{R}^m$ and $t \neq 0$, and where C is an $n \times m$ matrix of rank $m \leq n$. As in Section 42.2, use a QR -decomposition

$$C = P \begin{pmatrix} R \\ 0 \end{pmatrix},$$

where P is an orthogonal $n \times n$ matrix and R is an $m \times m$ invertible upper triangular matrix, and write

$$x = P \begin{pmatrix} y \\ z \end{pmatrix},$$

to deduce that

$$R^\top y = t.$$

Give the details of the reduction of this constrained minimization problem to an unconstrained minimization problem involving the matrix $P^\top AP$.

Problem 42.5. Find the maximum and the minimum of the function

$$Q(x, y) = \begin{pmatrix} x & y \end{pmatrix} \begin{pmatrix} 1 & 2 \\ 2 & 1 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix}$$

on the unit circle $x^2 + y^2 = 1$.

Chapter 43

Schur Complements and Applications

Schur complements arise naturally in the process of inverting block matrices of the form

$$M = \begin{pmatrix} A & B \\ C & D \end{pmatrix}$$

and in characterizing when symmetric versions of these matrices are positive definite or positive semidefinite. These characterizations come up in various quadratic optimization problems; see Boyd and Vandenberghe [29], especially Appendix B. In the most general case, pseudo-inverses are also needed.

In this chapter we introduce Schur complements and describe several interesting ways in which they are used. Along the way we provide some details and proofs of some results from Appendix A.5 (especially Section A.5.5) of Boyd and Vandenberghe [29].

43.1 Schur Complements

Let M be an $n \times n$ matrix written as a 2×2 block matrix

$$M = \begin{pmatrix} A & B \\ C & D \end{pmatrix},$$

where A is a $p \times p$ matrix and D is a $q \times q$ matrix, with $n = p + q$ (so B is a $p \times q$ matrix and C is a $q \times p$ matrix). We can try to solve the linear system

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} c \\ d \end{pmatrix},$$

that is,

$$\begin{aligned} Ax + By &= c, \\ Cx + Dy &= d, \end{aligned}$$

by mimicking Gaussian elimination. If we assume that D is invertible, then we first solve for y , getting

$$y = D^{-1}(d - Cx),$$

and after substituting this expression for y in the first equation, we get

$$Ax + B(D^{-1}(d - Cx)) = c,$$

that is,

$$(A - BD^{-1}C)x = c - BD^{-1}d.$$

If the matrix $A - BD^{-1}C$ is invertible, then we obtain the solution to our system

$$\begin{aligned} x &= (A - BD^{-1}C)^{-1}(c - BD^{-1}d), \\ y &= D^{-1}(d - C(A - BD^{-1}C)^{-1}(c - BD^{-1}d)). \end{aligned}$$

If A is invertible, then by eliminating x first using the first equation, we obtain analogous formulas involving the matrix $D - CA^{-1}B$. The above formulas suggest that the matrices $A - BD^{-1}C$ and $D - CA^{-1}B$ play a special role and suggest the following definition:

Definition 43.1. Given any $n \times n$ block matrix of the form

$$M = \begin{pmatrix} A & B \\ C & D \end{pmatrix},$$

where A is a $p \times p$ matrix and D is a $q \times q$ matrix, with $n = p + q$ (so B is a $p \times q$ matrix and C is a $q \times p$ matrix), if D is invertible, then the matrix $A - BD^{-1}C$ is called the *Schur complement* of D in M . If A is invertible, then the matrix $D - CA^{-1}B$ is called the *Schur complement* of A in M .

The above equations written as

$$\begin{aligned} x &= (A - BD^{-1}C)^{-1}c - (A - BD^{-1}C)^{-1}BD^{-1}d, \\ y &= -D^{-1}C(A - BD^{-1}C)^{-1}c \\ &\quad + (D^{-1} + D^{-1}C(A - BD^{-1}C)^{-1}BD^{-1})d, \end{aligned}$$

yield a formula for the inverse of M in terms of the Schur complement of D in M , namely

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix}^{-1} = \begin{pmatrix} (A - BD^{-1}C)^{-1} & -(A - BD^{-1}C)^{-1}BD^{-1} \\ -D^{-1}C(A - BD^{-1}C)^{-1} & D^{-1} + D^{-1}C(A - BD^{-1}C)^{-1}BD^{-1} \end{pmatrix}.$$

A moment of reflection reveals that

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix}^{-1} = \begin{pmatrix} (A - BD^{-1}C)^{-1} & 0 \\ -D^{-1}C(A - BD^{-1}C)^{-1} & D^{-1} \end{pmatrix} \begin{pmatrix} I & -BD^{-1} \\ 0 & I \end{pmatrix},$$

and then

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix}^{-1} = \begin{pmatrix} I & 0 \\ -D^{-1}C & I \end{pmatrix} \begin{pmatrix} (A - BD^{-1}C)^{-1} & 0 \\ 0 & D^{-1} \end{pmatrix} \begin{pmatrix} I & -BD^{-1} \\ 0 & I \end{pmatrix}.$$

By taking inverses, we obtain the following result.

Proposition 43.1. *If the matrix D is invertible, then*

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix} = \begin{pmatrix} I & BD^{-1} \\ 0 & I \end{pmatrix} \begin{pmatrix} A - BD^{-1}C & 0 \\ 0 & D \end{pmatrix} \begin{pmatrix} I & 0 \\ D^{-1}C & I \end{pmatrix}.$$

The above expression can be checked directly and has the advantage of requiring only the invertibility of D .

Remark: If A is invertible, then we can use the Schur complement $D - CA^{-1}B$ of A to obtain the following factorization of M :

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix} = \begin{pmatrix} I & 0 \\ CA^{-1} & I \end{pmatrix} \begin{pmatrix} A & 0 \\ 0 & D - CA^{-1}B \end{pmatrix} \begin{pmatrix} I & A^{-1}B \\ 0 & I \end{pmatrix}.$$

If $D - CA^{-1}B$ is invertible, we can invert all three matrices above, and we get another formula for the inverse of M in terms of $(D - CA^{-1}B)$, namely,

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix}^{-1} = \begin{pmatrix} A^{-1} + A^{-1}B(D - CA^{-1}B)^{-1}CA^{-1} & -A^{-1}B(D - CA^{-1}B)^{-1} \\ -(D - CA^{-1}B)^{-1}CA^{-1} & (D - CA^{-1}B)^{-1} \end{pmatrix}.$$

If A, D and both Schur complements $A - BD^{-1}C$ and $D - CA^{-1}B$ are all invertible, by comparing the two expressions for M^{-1} , we get the (non-obvious) formula

$$(A - BD^{-1}C)^{-1} = A^{-1} + A^{-1}B(D - CA^{-1}B)^{-1}CA^{-1}.$$

Using this formula, we obtain another expression for the inverse of M involving the Schur complements of A and D (see Horn and Johnson [95]):

Proposition 43.2. *If A, D and both Schur complements $A - BD^{-1}C$ and $D - CA^{-1}B$ are all invertible, then*

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix}^{-1} = \begin{pmatrix} (A - BD^{-1}C)^{-1} & -A^{-1}B(D - CA^{-1}B)^{-1} \\ -(D - CA^{-1}B)^{-1}CA^{-1} & (D - CA^{-1}B)^{-1} \end{pmatrix}.$$

If we set $D = I$ and change B to $-B$, we get

$$(A + BC)^{-1} = A^{-1} - A^{-1}B(I - CA^{-1}B)^{-1}CA^{-1},$$

a formula known as the *matrix inversion lemma* (see Boyd and Vandenberghe [29], Appendix C.4, especially C.4.3).

43.2 Symmetric Positive Definite Matrices and Schur Complements

If we assume that our block matrix M is symmetric, so that A, D are symmetric and $C = B^\top$, then we see by Proposition 43.1 that M is expressed as

$$M = \begin{pmatrix} A & B \\ B^\top & D \end{pmatrix} = \begin{pmatrix} I & BD^{-1} \\ 0 & I \end{pmatrix} \begin{pmatrix} A - BD^{-1}B^\top & 0 \\ 0 & D \end{pmatrix} \begin{pmatrix} I & BD^{-1} \\ 0 & I \end{pmatrix}^\top,$$

which shows that M is similar to a block diagonal matrix (obviously, the Schur complement, $A - BD^{-1}B^\top$, is symmetric). As a consequence, we have the following version of “Schur’s trick” to check whether $M \succ 0$ for a symmetric matrix.

Proposition 43.3. *For any symmetric matrix M of the form*

$$M = \begin{pmatrix} A & B \\ B^\top & C \end{pmatrix},$$

if C is invertible, then the following properties hold:

- (1) $M \succ 0$ iff $C \succ 0$ and $A - BC^{-1}B^\top \succ 0$.
- (2) If $C \succ 0$, then $M \succeq 0$ iff $A - BC^{-1}B^\top \succeq 0$.

Proof. (1) Since C is invertible, we have

$$M = \begin{pmatrix} A & B \\ B^\top & C \end{pmatrix} = \begin{pmatrix} I & BC^{-1} \\ 0 & I \end{pmatrix} \begin{pmatrix} A - BC^{-1}B^\top & 0 \\ 0 & C \end{pmatrix} \begin{pmatrix} I & BC^{-1} \\ 0 & I \end{pmatrix}^\top. \quad (*)$$

Observe that

$$\begin{pmatrix} I & BC^{-1} \\ 0 & I \end{pmatrix}^{-1} = \begin{pmatrix} I & -BC^{-1} \\ 0 & I \end{pmatrix},$$

so $(*)$ yields

$$\begin{pmatrix} I & -BC^{-1} \\ 0 & I \end{pmatrix} \begin{pmatrix} A & B \\ B^\top & C \end{pmatrix} \begin{pmatrix} I & -BC^{-1} \\ 0 & I \end{pmatrix}^\top = \begin{pmatrix} A - BC^{-1}B^\top & 0 \\ 0 & C \end{pmatrix},$$

and we know that for any symmetric matrix T , here $T = M$, and any invertible matrix N , here

$$N = \begin{pmatrix} I & -BC^{-1} \\ 0 & I \end{pmatrix},$$

the matrix T is positive definite ($T \succ 0$) iff NTN^\top (which is obviously symmetric) is positive definite ($NTN^\top \succ 0$). But a block diagonal matrix is positive definite iff each diagonal block is positive definite, which concludes the proof.

(2) This is because for any symmetric matrix T and any invertible matrix N , we have $T \succeq 0$ iff $NTN^\top \succeq 0$. \square

Another version of Proposition 43.3 using the Schur complement of A instead of the Schur complement of C also holds. The proof uses the factorization of M using the Schur complement of A (see Section 43.1).

Proposition 43.4. *For any symmetric matrix M of the form*

$$M = \begin{pmatrix} A & B \\ B^\top & C \end{pmatrix},$$

if A is invertible then the following properties hold:

- (1) $M \succ 0$ iff $A \succ 0$ and $C - B^\top A^{-1}B \succ 0$.
- (2) If $A \succ 0$, then $M \succeq 0$ iff $C - B^\top A^{-1}B \succeq 0$.

Here is an illustration of Proposition 43.4(2). Consider the nonlinear quadratic constraint

$$(Ax + b)^\top (Ax + b) \leq c^\top x + d,$$

were $A \in M_n(\mathbb{R})$, $x, b, c \in \mathbb{R}^n$ and $d \in \mathbb{R}$. Since obviously $I = I_n$ is invertible and $I \succ 0$, we have

$$\begin{pmatrix} I & Ax + b \\ (Ax + b)^\top & c^\top x + d \end{pmatrix} \succeq 0$$

iff $c^\top x + d - (Ax + b)^\top (Ax + b) \succeq 0$ iff $(Ax + b)^\top (Ax + b) \leq c^\top x + d$, since the matrix (a scalar) $c^\top x + d - (Ax + b)^\top (Ax + b)$ is the Schur complement of I in the above matrix.

The trick of using Schur complements to convert nonlinear inequality constraints into linear constraints on symmetric matrices involving the semidefinite ordering \succeq is used extensively to convert nonlinear problems into semidefinite programs; see Boyd and Vandenberghe [29].

When C is singular (or A is singular), it is still possible to characterize when a symmetric matrix M as above is positive semidefinite, but this requires using a version of the Schur complement involving the pseudo-inverse of C , namely $A - BC^+B^\top$ (or the Schur complement, $C - B^\top A^+B$, of A). We use the criterion of Proposition 42.5, which tells us when a quadratic function of the form $\frac{1}{2}x^\top Px - x^\top b$ has a minimum and what this optimum value is (where P is a symmetric matrix).

43.3 Symmetric Positive Semidefinite Matrices and Schur Complements

We now return to our original problem, characterizing when a symmetric matrix

$$M = \begin{pmatrix} A & B \\ B^\top & C \end{pmatrix}$$

is positive semidefinite. Thus, we want to know when the function

$$f(x, y) = (x^\top \ y^\top) \begin{pmatrix} A & B \\ B^\top & C \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = x^\top Ax + 2x^\top By + y^\top Cy$$

has a minimum with respect to both x and y . If we hold y constant, Proposition 42.5 implies that $f(x, y)$ has a minimum iff $A \succeq 0$ and $(I - AA^+)By = 0$, and then the minimum value is

$$f(x^*, y) = -y^\top B^\top A^+By + y^\top Cy = y^\top (C - B^\top A^+B)y.$$

Since we want $f(x, y)$ to be uniformly bounded from below for all x, y , we must have $(I - AA^+)B = 0$. Now $f(x^*, y)$ has a minimum iff $C - B^\top A^+B \succeq 0$. Therefore, we have established that $f(x, y)$ has a minimum over all x, y iff

$$A \succeq 0, \quad (I - AA^+)B = 0, \quad C - B^\top A^+B \succeq 0.$$

Similar reasoning applies if we first minimize with respect to y and then with respect to x , but this time, the Schur complement $A - BC^+B^\top$ of C is involved. Putting all these facts together, we get our main result:

Theorem 43.5. *Given any symmetric matrix*

$$M = \begin{pmatrix} A & B \\ B^\top & C \end{pmatrix}$$

the following conditions are equivalent:

- (1) $M \succeq 0$ (M is positive semidefinite).
- (2) $A \succeq 0, \quad (I - AA^+)B = 0, \quad C - B^\top A^+B \succeq 0$.
- (3) $C \succeq 0, \quad (I - CC^+)B^\top = 0, \quad A - BC^+B^\top \succeq 0$.

If $M \succeq 0$ as in Theorem 43.5, then it is easy to check that we have the following factorizations (using the fact that $A^+AA^+ = A^+$ and $C^+CC^+ = C^+$):

$$\begin{pmatrix} A & B \\ B^\top & C \end{pmatrix} = \begin{pmatrix} I & BC^+ \\ 0 & I \end{pmatrix} \begin{pmatrix} A - BC^+B^\top & 0 \\ 0 & C \end{pmatrix} \begin{pmatrix} I & 0 \\ C^+B^\top & I \end{pmatrix}$$

and

$$\begin{pmatrix} A & B \\ B^\top & C \end{pmatrix} = \begin{pmatrix} I & 0 \\ B^\top A^+ & I \end{pmatrix} \begin{pmatrix} A & 0 \\ 0 & C - B^\top A^+B \end{pmatrix} \begin{pmatrix} I & A^+B \\ 0 & I \end{pmatrix}.$$

43.4 Summary

The main concepts and results of this chapter are listed below:

- Schur complements.
- The matrix inversion lemma.
- Symmetric positive definite matrices and Schur complements.
- Symmetric positive semidefinite matrices and Schur complements.

43.5 Problems

Problem 43.1. Prove that maximizing the function $g(\lambda)$ given by

$$g(\lambda) = c_0 + \lambda c_1 - (b_0 + \lambda b_1)^\top (A_0 + \lambda A_1)^+ (b_0 + \lambda b_1),$$

subject to

$$A_0 + \lambda A_1 \succeq 0, \quad b_0 + \lambda b_1 \in \text{range}(A_0 + \lambda A_1),$$

with A_0, A_1 some $n \times n$ symmetric positive semidefinite matrices, $b_0, b_1 \in \mathbb{R}^n$, and $c_0, c_1 \in \mathbb{R}$, is equivalent to maximizing γ subject to the constraints

$$\begin{aligned} \lambda &\geq 0 \\ \begin{pmatrix} A_0 + \lambda A_1 & b_0 + \lambda b_1 \\ (b_0 + \lambda b_1)^\top & c_0 + \lambda c_1 - \gamma \end{pmatrix} &\succeq 0. \end{aligned}$$

Problem 43.2. Let a_1, \dots, a_m be m vectors in \mathbb{R}^n and assume that they span \mathbb{R}^n .

- (1) Prove that the matrix

$$\sum_{k=1}^m a_k a_k^\top$$

is symmetric positive definite.

- (2) Define the matrix X by

$$X = \left(\sum_{k=1}^m a_k a_k^\top \right)^{-1}.$$

Prove that

$$\begin{pmatrix} \sum_{k=1}^m a_k a_k^\top & a_i \\ a_i^\top & 1 \end{pmatrix} \succeq 0, \quad i = 1, \dots, m.$$

Deduce that

$$a_i^\top X a_i \leq 1, \quad 1 \leq i \leq m.$$

Problem 43.3. Consider the function g of Example 39.11 defined by

$$g(a, b, c) = \log(ac - b^2),$$

where $ac - b^2 > 0$. We found that the Hessian matrix of g is given by

$$Hg(a, b, c) = \frac{1}{(ac - b^2)^2} \begin{pmatrix} -c^2 & 2bc & -b^2 \\ 2bc & -2(b^2 + ac) & 2ab \\ -b^2 & 2ab & -a^2 \end{pmatrix}.$$

Use the Schur complement (of a^2) to prove that the matrix $-Hg(a, b, c)$ is symmetric positive definite if $ac - b^2 > 0$ and $a, c > 0$.

Part VII

Linear Optimization

Chapter 44

Convex Sets, Cones, \mathcal{H} -Polyhedra

44.1 What is Linear Programming?

What is *linear programming*? At first glance, one might think that this is some style of computer programming. After all, there is imperative programming, functional programming, object-oriented programming, *etc.* The term linear programming is somewhat misleading, because it really refers to a method for *planning* with linear constraints, or more accurately, an *optimization method* where both the objective function and the constraints are linear.¹

Linear programming was created in the late 1940's, one of the key players being George Dantzing, who invented the simplex algorithm. Kantorovitch also did some pioneering work on linear programming as early as 1939. The term *linear programming* has a military connotation because in the early 1950's it was used as a synonym for plans or schedules for training troops, logistical supply, resource allocation, *etc.* Unfortunately the term linear programming is well established and we are stuck with it.

Interestingly, even though originally most applications of linear programming were in the field of economics and industrial engineering, linear programming has become an important tool in theoretical computer science and in the theory of algorithms. Indeed, linear programming is often an effective tool for designing approximation algorithms to solve hard problems (typically NP-hard problems). Linear programming is also the “baby version” of convex programming, a very effective methodology which has received much attention in recent years.

Our goal is to present the mathematical underpinnings of linear programming, in particular the existence of an optimal solution if a linear program is feasible and bounded, and the duality theorem in linear programming, one of the deepest results in this field. The duality theorem in linear programming also has significant algorithmic implications but we do not discuss this here. We present the simplex algorithm, the dual simplex algorithm, and the primal dual algorithm. We also describe the tableau formalism for running the simplex

¹Again, we witness another unfortunate abuse of terminology; the constraints are in fact *affine*.

algorithm and its variants. A particularly nice feature of the tableau formalism is that the update of a tableau can be performed using elementary row operations identical to the operations used during the reduction of a matrix to row reduced echelon form (rref). What differs is the criterion for the choice of the pivot.

However, we do not discuss other methods such as the ellipsoid method or interior points methods. For these more algorithmic issues, we refer the reader to standard texts on linear programming. In our opinion, one of the clearest (and among the most concise!) is Matousek and Gardner [123]; Chvatal [40] and Schrijver [148] are classics. Papadimitriou and Steiglitz [134] offers a very crisp presentation in the broader context of combinatorial optimization, and Bertsimas and Tsitsiklis [21] and Vanderbei [181] are very complete.

Linear programming has to do with maximizing a linear cost function $c_1x_1 + \cdots + c_nx_n$ with respect to m “linear” inequalities of the form

$$a_{i1}x_1 + \cdots + a_{in}x_n \leq b_i.$$

These constraints can be put together into an $m \times n$ matrix $A = (a_{ij})$, and written more concisely as

$$Ax \leq b.$$

For technical reasons that will appear clearer later on, it is often preferable to add the nonnegativity constraints $x_i \geq 0$ for $i = 1, \dots, n$. We write $x \geq 0$. It is easy to show that every linear program is equivalent to another one satisfying the constraints $x \geq 0$, at the expense of adding new variables that are also constrained to be nonnegative. Let $\mathcal{P}(A, b)$ be the set of *feasible solutions* of our linear program given by

$$\mathcal{P}(A, b) = \{x \in \mathbb{R}^n \mid Ax \leq b, x \geq 0\}.$$

Then there are two basic questions:

- (1) Is $\mathcal{P}(A, b)$ nonempty, that is, does our linear program have a chance to have a solution?
- (2) Does the objective function $c_1x_1 + \cdots + c_nx_n$ have a maximum value on $\mathcal{P}(A, b)$?

The answer to both questions can be **no**. But if $\mathcal{P}(A, b)$ is nonempty and if the objective function is bounded above (on $\mathcal{P}(A, b)$), then it can be shown that the maximum of $c_1x_1 + \cdots + c_nx_n$ is achieved by some $x \in \mathcal{P}(A, b)$. Such a solution is called an *optimal solution*. Perhaps surprisingly, this result is not so easy to prove (unless one has the simplex method at his disposal). We will prove this result in full detail (see Proposition 45.1).

The reason why linear constraints are so important is that the domain of potential optimal solutions $\mathcal{P}(A, b)$ is *convex*. In fact, $\mathcal{P}(A, b)$ is a convex polyhedron which is the intersection of half-spaces cut out by affine hyperplanes. The objective function being linear is convex, and this is also a crucial fact. Thus, we are led to study convex sets, in particular those that arise from solutions of inequalities defined by affine forms, but also convex cones.

We give a brief introduction to these topics. As a reward, we provide several criteria for testing whether a system of inequalities

$$Ax \leq b, \quad x \geq 0$$

has a solution or not in terms of versions of the *Farkas lemma* (see Proposition 50.3 and Proposition 47.4). Then we give a complete proof of the strong duality theorem for linear programming (see Theorem 47.7). We also discuss the complementary slackness conditions and show that they can be exploited to design an algorithm for solving a linear program that uses both the primal problem and its dual. This algorithm known as the *primal dual algorithm*, although not used much nowadays, has been the source of inspiration for a whole class of approximation algorithms also known as primal dual algorithms.

We hope that this chapter and the next three will be a motivation for learning more about linear programming, convex optimization, but also convex geometry. The “bible” in convex optimization is Boyd and Vandenberghe [29], and one of the best sources for convex geometry is Ziegler [195]. This is a rather advanced text, so the reader may want to begin with Gallier [73].

44.2 Affine Subsets, Convex Sets, Affine Hyperplanes, Half-Spaces

We view \mathbb{R}^n as consisting of *column vectors* ($n \times 1$ matrices). As usual, row vectors represent *linear forms*, that is linear maps $\varphi: \mathbb{R}^n \rightarrow \mathbb{R}$, in the sense that the row vector y (a $1 \times n$ matrix) represents the linear form φ if $\varphi(x) = yx$ for all $x \in \mathbb{R}^n$. We denote the space of linear forms (row vectors) by $(\mathbb{R}^n)^*$.

Recall that a *linear combination* of vectors in \mathbb{R}^n is an expression

$$\lambda_1 x_1 + \cdots + \lambda_m x_m$$

where $x_1, \dots, x_m \in \mathbb{R}^n$ and where $\lambda_1, \dots, \lambda_m$ are *arbitrary* scalars in \mathbb{R} . Given a sequence of vectors $S = (x_1, \dots, x_m)$ with $x_i \in \mathbb{R}^n$, the set of all linear combinations of the vectors in S is the smallest (linear) subspace containing S called the *linear span* of S , and denoted $\text{span}(S)$. A *linear subspace* of \mathbb{R}^n is any nonempty subset of \mathbb{R}^n closed under linear combinations.

Definition 44.1. An *affine combination* of vectors in \mathbb{R}^n is an expression

$$\lambda_1 x_1 + \cdots + \lambda_m x_m$$

where $x_1, \dots, x_m \in \mathbb{R}^n$ and where $\lambda_1, \dots, \lambda_m$ are scalars in \mathbb{R} *satisfying the condition*

$$\lambda_1 + \cdots + \lambda_m = 1.$$

Given a sequence of vectors $S = (x_1, \dots, x_m)$ with $x_i \in \mathbb{R}^n$, the set of all affine combinations of the vectors in S is the smallest affine subspace containing S called the *affine hull* of S and denoted $\text{aff}(S)$.

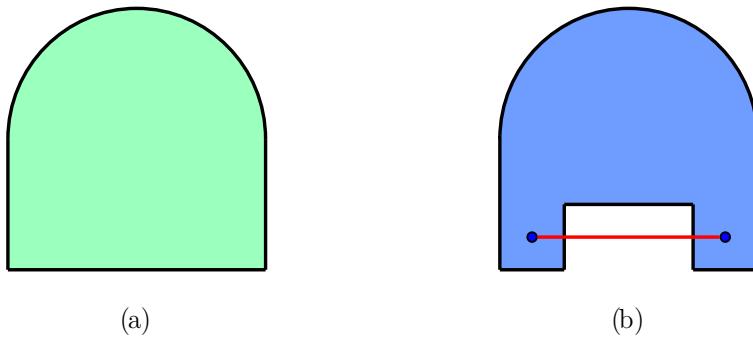

Figure 44.1: (a) A convex set; (b) A nonconvex set

Definition 44.2. An *affine subspace* A of \mathbb{R}^n is any subset of \mathbb{R}^n closed under affine combinations.

If A is a nonempty affine subspace of \mathbb{R}^n , then it can be shown that $V_A = \{a - b \mid a, b \in A\}$ is a linear subspace of \mathbb{R}^n and that

$$A = a + V_A = \{a + v \mid v \in V_A\}$$

for any $a \in A$; see Gallier [72] (Section 2.5).

Definition 44.3. Given an affine subspace A , the linear space $V_A = \{a - b \mid a, b \in A\}$ is called the *direction* of A . The *dimension* of the nonempty affine subspace A is the dimension of its direction V_A .

Definition 44.4. *Convex combinations* are affine combinations $\lambda_1 x_1 + \cdots + \lambda_m x_m$ satisfying the extra condition that $\lambda_i \geq 0$ for $i = 1, \dots, m$.

A convex set is defined as follows.

Definition 44.5. A subset V of \mathbb{R}^n is *convex* if for any two points $a, b \in V$, we have $c \in V$ for every point $c = (1 - \lambda)a + \lambda b$, with $0 \leq \lambda \leq 1$ ($\lambda \in \mathbb{R}$). Given any two points a, b , the notation $[a, b]$ is often used to denote the line segment between a and b , that is,

$$[a, b] = \{c \in \mathbb{R}^n \mid c = (1 - \lambda)a + \lambda b, 0 \leq \lambda \leq 1\},$$

and thus a set V is convex if $[a, b] \subseteq V$ for any two points $a, b \in V$ ($a = b$ is allowed). The *dimension* of a convex set V is the dimension of its affine hull $\text{aff}(V)$.

The empty set is trivially convex, every one-point set $\{a\}$ is convex, and the entire affine space \mathbb{R}^n is convex.

It is obvious that the intersection of any family (finite or infinite) of convex sets is convex.

Definition 44.6. Given any (nonempty) subset S of \mathbb{R}^n , the smallest convex set containing S is denoted by $\text{conv}(S)$ and called the *convex hull* of S (it is the intersection of all convex sets containing S).

It is essential not only to have a good understanding of $\text{conv}(S)$, but to also have good methods for computing it. We have the following simple but crucial result.

Proposition 44.1. For any family $S = (a_i)_{i \in I}$ of points in \mathbb{R}^n , the set V of convex combinations $\sum_{i \in I} \lambda_i a_i$ (where $\sum_{i \in I} \lambda_i = 1$ and $\lambda_i \geq 0$) is the convex hull $\text{conv}(S)$ of $S = (a_i)_{i \in I}$.

It is natural to wonder whether Proposition 44.1 can be sharpened in two directions: (1) Is it possible to have a fixed bound on the number of points involved in the convex combinations? (2) Is it necessary to consider convex combinations of all points, or is it possible to consider only a subset with special properties?

The answer is yes in both cases. In Case 1, Carathéodory's theorem asserts that it is enough to consider convex combinations of $n + 1$ points. For example, in the plane \mathbb{R}^2 , the convex hull of a set S of points is the union of all triangles (interior points included) with vertices in S . In Case 2, the theorem of Krein and Milman asserts that a convex set that is also compact is the convex hull of its extremal points (given a convex set S , a point $a \in S$ is *extremal* if $S - \{a\}$ is also convex).

We will not prove these theorems here, but we invite the reader to consult Gallier [73] or Berger [12].

Convex sets also arise as half-spaces cut out by affine hyperplanes.

Definition 44.7. An *affine form* $\varphi: \mathbb{R}^n \rightarrow \mathbb{R}$ is defined by some linear form $c \in (\mathbb{R}^n)^*$ and some scalar $\beta \in \mathbb{R}$ so that

$$\varphi(x) = cx + \beta \quad \text{for all } x \in \mathbb{R}^n.$$

If $c \neq 0$, the affine form φ specified by (c, β) defines the *affine hyperplane* (for short *hyperplane*) $H(\varphi)$ given by

$$H(\varphi) = \{x \in \mathbb{R}^n \mid \varphi(x) = 0\} = \{x \in \mathbb{R}^n \mid cx + \beta = 0\},$$

and the two *(closed) half-spaces*

$$\begin{aligned} H_+(\varphi) &= \{x \in \mathbb{R}^n \mid \varphi(x) \geq 0\} = \{x \in \mathbb{R}^n \mid cx + \beta \geq 0\}, \\ H_-(\varphi) &= \{x \in \mathbb{R}^n \mid \varphi(x) \leq 0\} = \{x \in \mathbb{R}^n \mid cx + \beta \leq 0\}. \end{aligned}$$

When $\beta = 0$, we call H a *linear hyperplane*.

Both $H_+(\varphi)$ and $H_-(\varphi)$ are convex and $H = H_+(\varphi) \cap H_-(\varphi)$.

For example, $\varphi: \mathbb{R}^2 \rightarrow \mathbb{R}$ with $\varphi(x, y) = 2x + y + 3$ is an affine form defining the line given by the equation $y = -2x - 3$. Another example of an affine form is $\varphi: \mathbb{R}^3 \rightarrow \mathbb{R}$

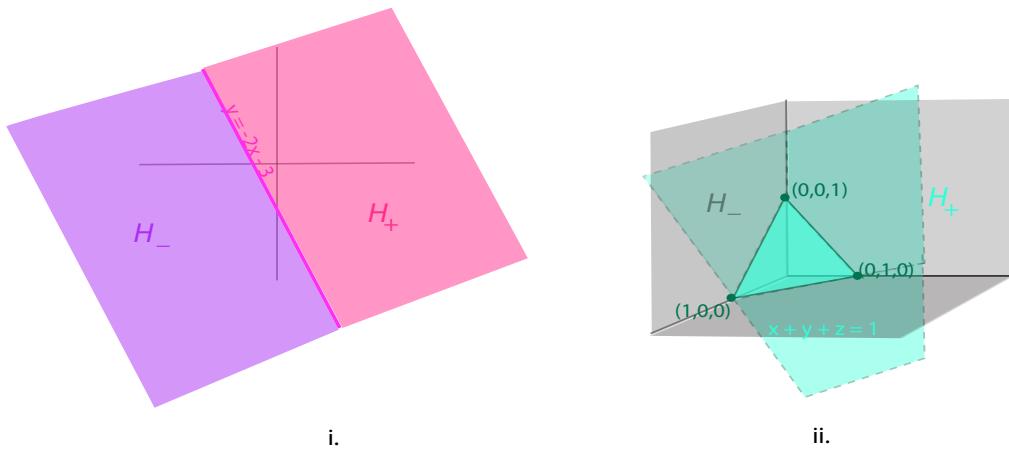

Figure 44.2: Figure i. illustrates the hyperplane $H(\varphi)$ for $\varphi(x, y) = 2x + y + 3$, while Figure ii. illustrates the hyperplane $H(\varphi)$ for $\varphi(x, y, z) = x + y + z - 1$.

with $\varphi(x, y, z) = x + y + z - 1$; this affine form defines the plane given by the equation $x + y + z = 1$, which is the plane through the points $(0, 0, 1)$, $(0, 1, 0)$, and $(1, 0, 0)$. Both of these hyperplanes are illustrated in Figure 44.2.

Definition 44.8. For any two vector $x, y \in \mathbb{R}^n$ with $x = (x_1, \dots, x_n)$ and $y = (y_1, \dots, y_n)$ we write $x \leq y$ iff $x_i \leq y_i$ for $i = 1, \dots, n$, and $x \geq y$ iff $y \leq x$. In particular $x \geq 0$ iff $x_i \geq 0$ for $i = 1, \dots, n$.

Certain special types of convex sets called cones and \mathcal{H} -polyhedra play an important role. The set of feasible solutions of a linear program is an \mathcal{H} -polyhedron, and cones play a crucial role in the proof of Proposition 45.1 and in the Farkas–Minkowski proposition (Proposition 47.2).

44.3 Cones, Polyhedral Cones, and \mathcal{H} -Polyhedra

Cones and polyhedral cones are defined as follows.

Definition 44.9. Given a nonempty subset $S \subseteq \mathbb{R}^n$, the *cone* $C = \text{cone}(S)$ spanned by S is the convex set

$$\text{cone}(S) = \left\{ \sum_{i=1}^k \lambda_i u_i, u_i \in S, \lambda_i \in \mathbb{R}, \lambda_i \geq 0 \right\},$$

of positive combinations of vectors from S . If S consists of a finite set of vectors, the cone $C = \text{cone}(S)$ is called a *polyhedral cone*. Figure 44.3 illustrates a polyhedral cone.

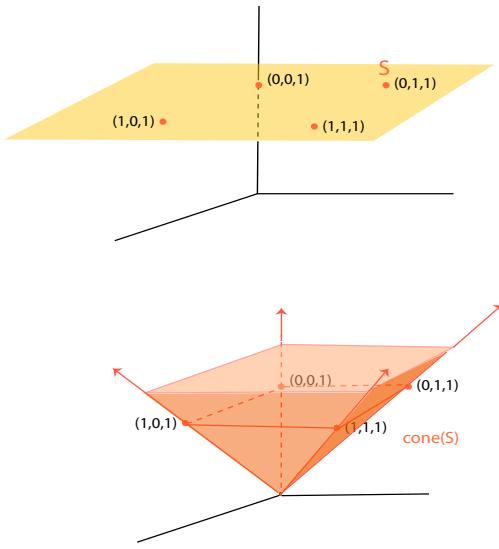

Figure 44.3: Let $S = \{(0, 0, 1), (1, 0, 1), (1, 1, 1), (0, 1, 1)\}$. The polyhedral cone, $\text{cone}(S)$, is the solid “pyramid” with apex at the origin and square cross sections.

Note that if some nonzero vector u belongs to a cone C , then $\lambda u \in C$ for all $\lambda \geq 0$, that is, the ray $\{\lambda u \mid \lambda \geq 0\}$ belongs to C .

Remark: The cones (and polyhedral cones) of Definition 44.9 are *always convex*. For this reason, we use the simpler terminology cone instead of convex cone. However, there are more general kinds of cones (see Definition 50.1) that are not convex (for example, a union of polyhedral cones or the linear cone generated by the curve in Figure 44.4), and if we were dealing with those we would refer to the cones of Definition 44.9 as convex cones.

Definition 44.10. An \mathcal{H} -polyhedron, for short a *polyhedron*, is any subset $\mathcal{P} = \bigcap_{i=1}^s C_i$ of \mathbb{R}^n defined as the intersection of a finite number s of closed half-spaces C_i . An example of an \mathcal{H} -polyhedron is shown in Figure 44.6. An \mathcal{H} -polytope is a bounded \mathcal{H} -polyhedron, which means that there is a closed ball $B_r(x)$ of center x and radius $r > 0$ such that $\mathcal{P} \subseteq B_r(x)$. An example of a \mathcal{H} -polytope is shown in Figure 44.5.

By convention, we agree that \mathbb{R}^n itself is an \mathcal{H} -polyhedron.

Remark: The \mathcal{H} -polyhedra of Definition 44.10 are always convex. For this reason, as in the case of cones we use the simpler terminology \mathcal{H} -polyhedron instead of convex \mathcal{H} -polyhedron. In algebraic topology, there are more general polyhedra that are not convex.

It can be shown that an \mathcal{H} -polytope \mathcal{P} is equal to the convex hull of finitely many points (the extreme points of \mathcal{P}). This is a nontrivial result whose proof takes a significant amount of work; see Gallier [73] and Ziegler [195].

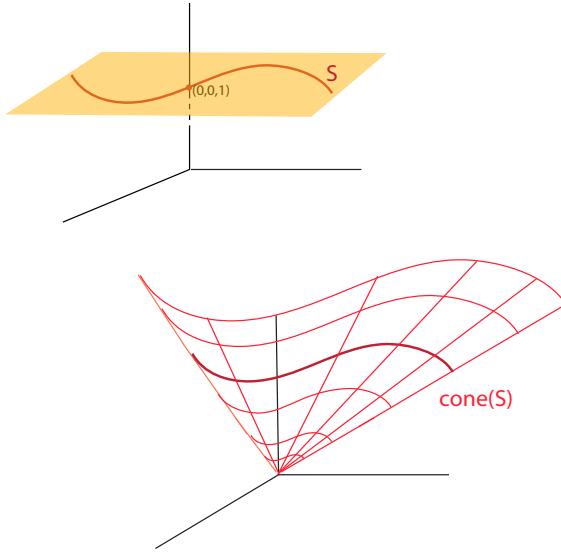

Figure 44.4: Let S be a planar curve in $z = 1$. The linear cone of S , consisting of all half rays connecting S to the origin, is not convex.

An unbounded \mathcal{H} -polyhedron is not equal to the convex hull of finite set of points. To obtain an equivalent notion we introduce the notion of a \mathcal{V} -polyhedron.

Definition 44.11. A \mathcal{V} -polyhedron is any convex subset $A \subseteq \mathbb{R}^n$ of the form

$$A = \text{conv}(Y) + \text{cone}(V) = \{a + v \mid a \in \text{conv}(Y), v \in \text{cone}(V)\},$$

where $Y \subseteq \mathbb{R}^n$ and $V \subseteq \mathbb{R}^n$ are *finite* (possibly empty).

When $V = \emptyset$ we simply have a *polytope*, and when $Y = \emptyset$ or $Y = \{0\}$, we simply have a cone.

It can be shown that every \mathcal{H} -polyhedron is a \mathcal{V} -polyhedron and conversely. This is one of the major theorems in the theory of polyhedra, and its proof is nontrivial. For a complete proof, see Gallier [73] and Ziegler [195].

Every polyhedral cone is closed. This is an important fact that is used in the proof of several other key results such as Proposition 45.1 and the Farkas–Minkowski proposition (Proposition 47.2).

Although it seems obvious that a polyhedral cone should be closed, a rigorous proof is not entirely trivial.

Indeed, the fact that a polyhedral cone is closed relies crucially on the fact that C is spanned by a *finite* number of vectors, because the cone generated by an infinite set may not be closed. For example, consider the closed disk $D \subseteq \mathbb{R}^2$ of center $(0, 1)$ and radius 1,

Figure 44.5: An icosahedron is an example of an \mathcal{H} -polytope.

which is tangent to the x -axis at the origin. Then the cone(D) consists of the open upper half-plane *plus* the origin $(0, 0)$, but this set is not closed.

Proposition 44.2. *Every polyhedral cone C is closed.*

Proof. This is proven by showing that

1. Every primitive cone is closed, where a *primitive cone* is a polyhedral cone spanned by linearly independent vectors.
2. A polyhedral cone C is the union of finitely many primitive cones.

Assume that (a_1, \dots, a_m) are linearly independent vectors in \mathbb{R}^n , and consider any sequence $(x^{(k)})_{k \geq 0}$

$$x^{(k)} = \sum_{i=1}^m \lambda_i^{(k)} a_i$$

of vectors in the primitive cone $\text{cone}(\{a_1, \dots, a_m\})$, which means that $\lambda_j^{(k)} \geq 0$ for $i = 1, \dots, m$ and all $k \geq 0$. The vectors $x^{(k)}$ belong to the subspace U spanned by (a_1, \dots, a_m) , and U is closed. Assume that the sequence $(x^{(k)})_{k \geq 0}$ converges to a limit $x \in \mathbb{R}^n$. Since U is closed and $x^{(k)} \in U$ for all $k \geq 0$, we have $x \in U$. If we write $x = x_1 a_1 + \dots + x_m a_m$, we would like to prove that $x_i \geq 0$ for $i = 1, \dots, m$. The sequence the $(x^{(k)})_{k \geq 0}$ converges to x iff

$$\lim_{k \rightarrow \infty} \|x^{(k)} - x\| = 0,$$

iff

$$\lim_{k \rightarrow \infty} \left(\sum_{i=1}^m |\lambda_i^{(k)} - x_i|^2 \right)^{1/2} = 0$$

iff

$$\lim_{k \rightarrow \infty} \lambda_i^{(k)} = x_i, \quad i = 1, \dots, m.$$

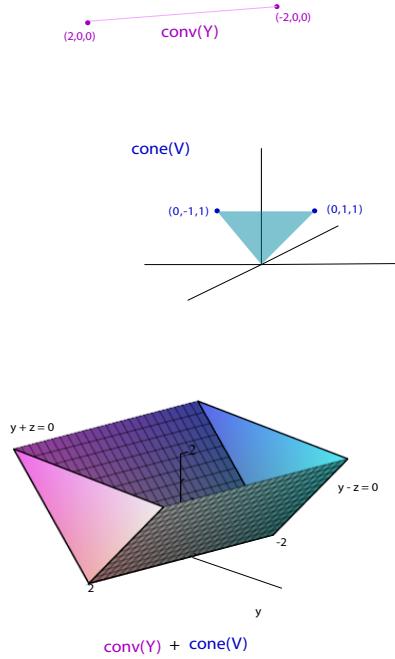

Figure 44.6: The “triangular trough” determined by the inequalities $y - z \leq 0$, $y + z \geq 0$, and $-2 \leq x \leq 2$ is an \mathcal{H} -polyhedron and an \mathcal{V} -polyhedron, where $Y = \{(2, 0, 0), (-2, 0, 0)\}$ and $V = \{(0, 1, 1), (0, -1, 1)\}$.

Since $\lambda_i^{(k)} \geq 0$ for $i = 1, \dots, m$ and all $k \geq 0$, we have $x_i \geq 0$ for $i = 1, \dots, m$, so $x \in \text{cone}(\{a_1, \dots, a_m\})$.

Next, assume that x belongs to the polyhedral cone C . Consider a positive combination

$$x = \lambda_1 a_1 + \dots + \lambda_k a_k, \quad (*_1)$$

for some nonzero $a_1, \dots, a_k \in C$, with $\lambda_i \geq 0$ and with k minimal. Since k is minimal, we must have $\lambda_i > 0$ for $i = 1, \dots, k$. We claim that (a_1, \dots, a_k) are linearly independent.

If not, there is some nontrivial linear combination

$$\mu_1 a_1 + \dots + \mu_k a_k = 0, \quad (*_2)$$

and since the a_i are nonzero, $\mu_j \neq 0$ for some at least some j . We may assume that $\mu_j < 0$ for some j (otherwise, we consider the family $(-\mu_i)_{1 \leq i \leq k}$), so let

$$J = \{j \in \{1, \dots, k\} \mid \mu_j < 0\}.$$

For any $t \in \mathbb{R}$, since $x = \lambda_1 a_1 + \dots + \lambda_k a_k$, using $(*_2)$ we get

$$x = (\lambda_1 + t\mu_1)a_1 + \dots + (\lambda_k + t\mu_k)a_k, \quad (*_3)$$

and if we pick

$$t = \min_{j \in J} \left(-\frac{\lambda_j}{\mu_j} \right) \geq 0,$$

we have $(\lambda_i + t\mu_i) \geq 0$ for $i = 1, \dots, k$, but $\lambda_j + t\mu_j = 0$ for some $j \in J$, so $(*_3)$ is an expression of x with less than k nonzero coefficients, contradicting the minimality of k in $(*_1)$. Therefore, (a_1, \dots, a_k) are linearly independent.

Since a polyhedral cone C is spanned by finitely many vectors, there are finitely many primitive cones (corresponding to linearly independent subfamilies), and since every $x \in C$, belongs to some primitive cone, C is the union of a finite number of primitive cones. Since every primitive cone is closed, as a union of finitely many closed sets, C itself is closed.

The above facts are also proven in Matousek and Gardner [123] (Chapter 6, Section 5, Lemma 6.5.3, 6.5.4, and 6.5.5). \square

Another way to prove that a polyhedral cone C is closed is to show that C is also a \mathcal{H} -polyhedron. This takes even more work; see Gallier [73] (Chapter 4, Section 4, Proposition 4.16). Yet another proof is given in Lax [113] (Chapter 13, Theorem 1).

44.4 Summary

The main concepts and results of this chapter are listed below:

- Affine combination.
- Affine hull.
- Affine subspace; direction of an affine subspace, dimension of an affine subspace.
- Convex combination.
- Convex set, dimension of a convex set.
- Convex hull.
- Affine form.
- Affine hyperplane, half-spaces.
- Cone, polyhedral cone.
- \mathcal{H} -polyhedron, \mathcal{H} -polytope.
- \mathcal{V} -polyhedron, polytope.
- Primitive cone.

44.5 Problems

Problem 44.1. Prove Proposition 44.1.

Problem 44.2. Describe an icosahedron both as an \mathcal{H} -polytope and as a \mathcal{V} -polytope. Do the same thing for a dodecahedron. What do you observe?

Chapter 45

Linear Programs

In this chapter we introduce linear programs and the basic notions relating to this concept. We define the \mathcal{H} -polyhedron $\mathcal{P}(A, b)$ of feasible solutions. Then we define bounded and unbounded linear programs and the notion of optimal solution. We define slack variables and the important notion of *linear program in standard form*.

We show that if a linear program in standard form has a feasible solution and is bounded above, then it has an optimal solution. This is not an obvious result and the proof relies on the fact that a polyhedral cone is closed (this result was shown in the previous chapter).

Next we show that in order to find optimal solutions it suffices to consider solutions of a special form called *basic feasible solutions*. We prove that if a linear program in standard form has a feasible solution and is bounded above, then some basic feasible solution is an optimal solution (Theorem 45.4).

Geometrically, a basic feasible solution corresponds to a *vertex*. In Theorem 45.6 we prove that a basic feasible solution of a linear program in standard form is a vertex of the polyhedron $\mathcal{P}(A, b)$. Finally, we prove that if a linear program in standard form has some feasible solution, then it has a basic feasible solution (see Theorem 45.7). This fact allows the simplex algorithm described in the next chapter to get started.

45.1 Linear Programs, Feasible Solutions, Optimal Solutions

The purpose of linear programming is to solve the following type of optimization problem.

Definition 45.1. A Linear Program (P) is the following kind of optimization problem:

$$\begin{aligned} & \text{maximize } cx \\ & \text{subject to} \\ & \quad a_1x \leq b_1 \\ & \quad \dots \\ & \quad a_m x \leq b_m \\ & \quad x \geq 0, \end{aligned}$$

where $x \in \mathbb{R}^n$, $c, a_1, \dots, a_m \in (\mathbb{R}^n)^*$, $b_1, \dots, b_m \in \mathbb{R}$.

The linear form c defines the *objective function* $x \mapsto cx$ of the Linear Program (P) (from \mathbb{R}^n to \mathbb{R}), and the inequalities $a_i x \leq b_i$ and $x_j \geq 0$ are called the *constraints* of the Linear Program (P).

If we define the $m \times n$ matrix

$$A = \begin{pmatrix} a_1 \\ \vdots \\ a_m \end{pmatrix}$$

whose rows are the row vectors a_1, \dots, a_m and b as the column vector

$$b = \begin{pmatrix} b_1 \\ \vdots \\ b_m \end{pmatrix},$$

the m inequality constraints $a_i x \leq b_i$ can be written in matrix form as

$$Ax \leq b.$$

Thus the Linear Program (P) can also be stated as the Linear Program (P):

$$\begin{aligned} & \text{maximize } cx \\ & \text{subject to } Ax \leq b \text{ and } x \geq 0. \end{aligned}$$

We should note that in many applications, the natural primal optimization problem is actually the *minimization* of some objective function $cx = c_1x_1 + \dots + c_nx_n$, rather its maximization. For example, many of the optimization problems considered in Papadimitriou and Steiglitz [134] are minimization problems.

Of course, minimizing cx is equivalent to maximizing $-cx$, so our presentation covers minimization too.

Here is an explicit example of a linear program of Type (P):

Example 45.1.

maximize $x_1 + x_2$

subject to

$$x_2 - x_1 \leq 1$$

$$x_1 + 6x_2 \leq 15$$

$$4x_1 - x_2 \leq 10$$

$$x_1 \geq 0, x_2 \geq 0,$$

and in matrix form

$$\text{maximize } (1 \ 1) \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}$$

subject to

$$\begin{pmatrix} -1 & 1 \\ 1 & 6 \\ 4 & -1 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \leq \begin{pmatrix} 1 \\ 15 \\ 10 \end{pmatrix}$$

$$x_1 \geq 0, x_2 \geq 0.$$

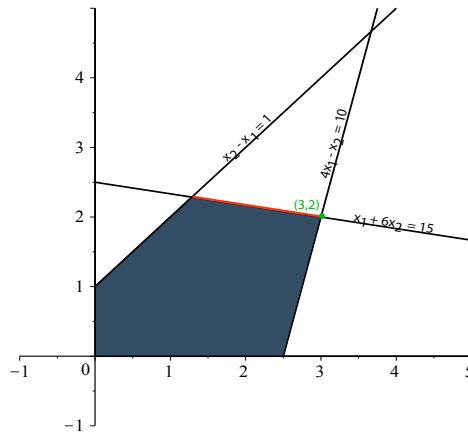

Figure 45.1: The \mathcal{H} -polyhedron associated with Example 45.1. The green point $(3, 2)$ is the unique optimal solution.

It turns out that $x_1 = 3, x_2 = 2$ yields the maximum of the objective function $x_1 + x_2$, which is 5. This is illustrated in Figure 45.1. Observe that the set of points that satisfy the above constraints is a convex region cut out by half planes determined by the lines of

equations

$$\begin{aligned}x_2 - x_1 &= 1 \\x_1 + 6x_2 &= 15 \\4x_1 - x_2 &= 10 \\x_1 &= 0 \\x_2 &= 0.\end{aligned}$$

In general, each constraint $a_i x \leq b_i$ corresponds to the affine form φ_i given by $\varphi_i(x) = a_i x - b_i$ and defines the half-space $H_-(\varphi_i)$, and each inequality $x_j \geq 0$ defines the half-space $H_+(x_j)$. The intersection of these half-spaces is the set of solutions of all these constraints. It is a (possibly empty) \mathcal{H} -polyhedron denoted $\mathcal{P}(A, b)$.

Definition 45.2. If $\mathcal{P}(A, b) = \emptyset$, we say that the Linear Program (P) has *no feasible solution*, and otherwise any $x \in \mathcal{P}(A, b)$ is called a *feasible solution* of (P) .

The linear program shown in Example 45.2 obtained by reversing the direction of the inequalities $x_2 - x_1 \leq 1$ and $4x_1 - x_2 \leq 10$ in the linear program of Example 45.1 has no feasible solution; see Figure 45.2.

Example 45.2.

$$\begin{aligned}\text{maximize } \quad & x_1 + x_2 \\ \text{subject to } \quad & x_1 - x_2 \leq -1 \\ & x_1 + 6x_2 \leq 15 \\ & x_2 - 4x_1 \leq -10 \\ & x_1 \geq 0, \quad x_2 \geq 0.\end{aligned}$$

Assume $\mathcal{P}(A, b) \neq \emptyset$, so that the Linear Program (P) has a feasible solution. In this case, consider the image $\{cx \in \mathbb{R} \mid x \in \mathcal{P}(A, b)\}$ of $\mathcal{P}(A, b)$ under the objective function $x \mapsto cx$.

Definition 45.3. If the set $\{cx \in \mathbb{R} \mid x \in \mathcal{P}(A, b)\}$ is unbounded above, then we say that the Linear Program (P) is *unbounded*.

The linear program shown in Example 45.3 obtained from the linear program of Example 45.1 by deleting the constraints $4x_1 - x_2 \leq 10$ and $x_1 + 6x_2 \leq 15$ is unbounded.

Example 45.3.

$$\begin{aligned}\text{maximize } \quad & x_1 + x_2 \\ \text{subject to } \quad & x_2 - x_1 \leq 1 \\ & x_1 \geq 0, \quad x_2 \geq 0.\end{aligned}$$

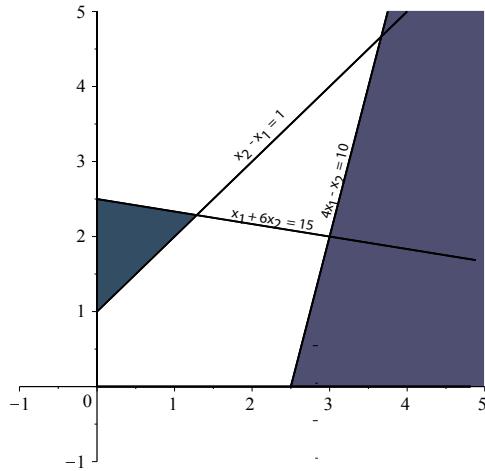

Figure 45.2: There is no \mathcal{H} -polyhedron associated with Example 45.2 since the blue and purple regions do not overlap.

Otherwise, we will prove shortly that if μ is the least upper bound of the set $\{cx \in \mathbb{R} \mid x \in \mathcal{P}(A, b)\}$, then there is some $p \in \mathcal{P}(A, b)$ such that

$$cp = \mu,$$

that is, the objective function $x \mapsto cx$ has a maximum value μ on $\mathcal{P}(A, b)$ which is achieved by some $p \in \mathcal{P}(A, b)$.

Definition 45.4. If the set $\{cx \in \mathbb{R} \mid x \in \mathcal{P}(A, b)\}$ is nonempty and bounded above, any point $p \in \mathcal{P}(A, b)$ such that $cp = \max\{cx \in \mathbb{R} \mid x \in \mathcal{P}(A, b)\}$ is called an *optimal solution* (or *optimum*) of (P) . Optimal solutions are often denoted by an upper *; for example, p^* .

The linear program of Example 45.1 has a unique optimal solution $(3, 2)$, but observe that the linear program of Example 45.4 in which the objective function is $(1/6)x_1 + x_2$ has infinitely many optimal solutions; the maximum of the objective function is $15/6$ which occurs along the points of orange boundary line in Figure 45.1.

Example 45.4.

$$\begin{aligned} & \text{maximize} && \frac{1}{6}x_1 + x_2 \\ & \text{subject to} && \\ & && x_2 - x_1 \leq 1 \\ & && x_1 + 6x_2 \leq 15 \\ & && 4x_1 - x_2 \leq 10 \\ & && x_1 \geq 0, x_2 \geq 0. \end{aligned}$$

The proof that if the set $\{cx \in \mathbb{R} \mid x \in \mathcal{P}(A, b)\}$ is nonempty and bounded above, then there is an optimal solution $p \in \mathcal{P}(A, b)$, is not as trivial as it might seem. It relies on the fact that a polyhedral cone is closed, a fact that was shown in Section 44.3.

We also use a trick that makes the proof simpler, which is that a Linear Program (P) with inequality constraints $Ax \leq b$

$$\begin{aligned} & \text{maximize} && cx \\ & \text{subject to} && Ax \leq b \text{ and } x \geq 0, \end{aligned}$$

is equivalent to the Linear Program (P_2) with equality constraints

$$\begin{aligned} & \text{maximize} && \hat{c}\hat{x} \\ & \text{subject to} && \hat{A}\hat{x} = b \text{ and } \hat{x} \geq 0, \end{aligned}$$

where \hat{A} is an $m \times (n+m)$ matrix, \hat{c} is a linear form in $(\mathbb{R}^{n+m})^*$, and $\hat{x} \in \mathbb{R}^{n+m}$, given by

$$\hat{A} = (A \ I_m), \quad \hat{c} = (c \ 0_m^\top), \quad \text{and} \quad \hat{x} = \begin{pmatrix} x \\ z \end{pmatrix},$$

with $x \in \mathbb{R}^n$ and $z \in \mathbb{R}^m$.

Indeed, $\hat{A}\hat{x} = b$ and $\hat{x} \geq 0$ iff

$$Ax + z = b, \quad x \geq 0, \quad z \geq 0,$$

iff

$$Ax \leq b, \quad x \geq 0,$$

and $\hat{c}\hat{x} = cx$.

Definition 45.5. The variables z are called *slack variables*, and a linear program of the form (P_2) is called a linear program in *standard form*.

The result of converting the linear program of Example 45.4 to standard form is the program shown in Example 45.5.

Example 45.5.

$$\begin{aligned} & \text{maximize} && \frac{1}{6}x_1 + x_2 \\ & \text{subject to} && \begin{aligned} x_2 - x_1 + z_1 &= 1 \\ x_1 + 6x_2 + z_2 &= 15 \\ 4x_1 - x_2 + z_3 &= 10 \\ x_1 \geq 0, x_2 \geq 0, z_1 \geq 0, z_2 \geq 0, z_3 \geq 0. \end{aligned} \end{aligned}$$

We can now prove that if a linear program has a feasible solution and is bounded, then it has an optimal solution.

Proposition 45.1. *Let (P_2) be a linear program in standard form, with equality constraint $Ax = b$. If $\mathcal{P}(A, b)$ is nonempty and bounded above, and if μ is the least upper bound of the set $\{cx \in \mathbb{R} \mid x \in \mathcal{P}(A, b)\}$, then there is some $p \in \mathcal{P}(A, b)$ such that*

$$cp = \mu,$$

that is, the objective function $x \mapsto cx$ has a maximum value μ on $\mathcal{P}(A, b)$ which is achieved by some optimum solution $p \in \mathcal{P}(A, b)$.

Proof. Since $\mu = \sup\{cx \in \mathbb{R} \mid x \in \mathcal{P}(A, b)\}$, there is a sequence $(x^{(k)})_{k \geq 0}$ of vectors $x^{(k)} \in \mathcal{P}(A, b)$ such that $\lim_{k \rightarrow \infty} cx^{(k)} = \mu$. In particular, if we write $x^{(k)} = (x_1^{(k)}, \dots, x_n^{(k)})$ we have $x_j^{(k)} \geq 0$ for $j = 1, \dots, n$ and for all $k \geq 0$. Let \tilde{A} be the $(m+1) \times n$ matrix

$$\tilde{A} = \begin{pmatrix} c \\ A \end{pmatrix},$$

and consider the sequence $(\tilde{A}x^{(k)})_{k \geq 0}$ of vectors $\tilde{A}x^{(k)} \in \mathbb{R}^{m+1}$. We have

$$\tilde{A}x^{(k)} = \begin{pmatrix} c \\ A \end{pmatrix} x^{(k)} = \begin{pmatrix} cx^{(k)} \\ Ax^{(k)} \end{pmatrix} = \begin{pmatrix} cx^{(k)} \\ b \end{pmatrix},$$

since by hypothesis $x^{(k)} \in \mathcal{P}(A, b)$, and the constraints are $Ax = b$ and $x \geq 0$. Since by hypothesis $\lim_{k \rightarrow \infty} cx^{(k)} = \mu$, the sequence $(\tilde{A}x^{(k)})_{k \geq 0}$ converges to the vector $\begin{pmatrix} \mu \\ b \end{pmatrix}$. Now, observe that each vector $\tilde{A}x^{(k)}$ can be written as the convex combination

$$\tilde{A}x^{(k)} = \sum_{j=1}^n x_j^{(k)} \tilde{A}^j,$$

with $x_j^{(k)} \geq 0$ and where $\tilde{A}^j \in \mathbb{R}^{m+1}$ is the j th column of \tilde{A} . Therefore, $\tilde{A}x^{(k)}$ belongs to the polyhedral cone

$$C = \text{cone}(\tilde{A}^1, \dots, \tilde{A}^n) = \{\tilde{A}x \mid x \in \mathbb{R}^n, x \geq 0\},$$

and since by Proposition 44.2 this cone is closed, $\lim_{k \geq \infty} \tilde{A}x^{(k)} \in C$, which means that there is some $u \in \mathbb{R}^n$ with $u \geq 0$ such that

$$\begin{pmatrix} \mu \\ b \end{pmatrix} = \lim_{k \geq \infty} \tilde{A}x^{(k)} = \tilde{A}u = \begin{pmatrix} cu \\ Au \end{pmatrix},$$

that is, $cu = \mu$ and $Au = b$. Hence, u is an optimal solution of (P_2) . \square

The next question is, how do we find such an optimal solution? It turns out that for linear programs in standard form where the constraints are of the form $Ax = b$ and $x \geq 0$, there are always optimal solutions of a special type called *basic feasible solutions*.

45.2 Basic Feasible Solutions and Vertices

If the system $Ax = b$ has a solution and if some row of A is a linear combination of other rows, then the corresponding equation is redundant, so we may assume that the rows of A are linearly independent; that is, we may assume that A has rank m , so $m \leq n$.

Definition 45.6. If A is an $m \times n$ matrix, for any nonempty subset K of $\{1, \dots, n\}$, let A_K be the submatrix of A consisting of the columns of A whose indices belong to K . We denote the j th column of the matrix A by A^j .

Definition 45.7. Given a Linear Program (P_2)

$$\begin{aligned} &\text{maximize} && cx \\ &\text{subject to} && Ax = b \text{ and } x \geq 0, \end{aligned}$$

where A has rank m , a vector $x \in \mathbb{R}^n$ is a *basic feasible solution* of (P) if $x \in \mathcal{P}(A, b) \neq \emptyset$, and if there is some subset K of $\{1, \dots, n\}$ of size m such that

- (1) The matrix A_K is invertible (that is, the columns of A_K are linearly independent).
- (2) $x_j = 0$ for all $j \notin K$.

The subset K is called a *basis* of x . Every index $k \in K$ is called *basic*, and every index $j \notin K$ is called *nonbasic*. Similarly, the columns A^k corresponding to indices $k \in K$ are called *basic*, and the columns A^j corresponding to indices $j \notin K$ are called *nonbasic*. The variables corresponding to basic indices $k \in K$ are called *basic variables*, and the variables corresponding to indices $j \notin K$ are called *nonbasic*.

For example, the linear program

$$\begin{aligned} &\text{maximize} && x_1 + x_2 \\ &\text{subject to} && x_1 + x_2 + x_3 = 1 \text{ and } x_1 \geq 0, x_2 \geq 0, x_3 \geq 0, \end{aligned} \quad (*)$$

has three basic feasible solutions; the basic feasible solution $K = \{1\}$ corresponds to the point $(1, 0, 0)$; the basic feasible solution $K = \{2\}$ corresponds to the point $(0, 1, 0)$; the basic feasible solution $K = \{3\}$ corresponds to the point $(0, 0, 1)$. Each of these points corresponds to the vertices of the slanted purple triangle illustrated in Figure 45.3. The vertices $(1, 0, 0)$ and $(0, 1, 0)$ optimize the objective function with a value of 1.

We now show that if the Standard Linear Program (P_2) as in Definition 45.7 has some feasible solution and is bounded above, then some basic feasible solution is an optimal solution. We follow Matousek and Gardner [123] (Chapter 4, Section 2, Theorem 4.2.3).

First we obtain a more convenient characterization of a basic feasible solution.

Proposition 45.2. *Given any Standard Linear Program (P_2) where $Ax = b$ and A is an $m \times n$ matrix of rank m , for any feasible solution x , if $J_> = \{j \in \{1, \dots, n\} \mid x_j > 0\}$, then x is a basic feasible solution iff the columns of the matrix $A_{J_>}$ are linearly independent.*

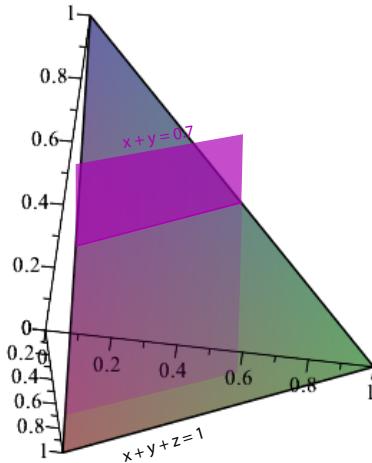

Figure 45.3: The \mathcal{H} -polytope associated with Linear Program (*). The objective function (with $x_1 \rightarrow x$ and $x_2 \rightarrow y$) is represented by vertical planes parallel to the purple plane $x + y = 0.7$, and reaches its maximal value when $x + y = 1$.

Proof. If x is a basic feasible solution, then there is some subset $K \subseteq \{1, \dots, n\}$ of size m such that the columns of A_K are linearly independent and $x_j = 0$ for all $j \notin K$, so by definition, $J_> \subseteq K$, which implies that the columns of the matrix $A_{J_>}$ are linearly independent.

Conversely, assume that x is a feasible solution such that the columns of the matrix $A_{J_>}$ are linearly independent. If $|J_>| = m$, we are done since we can pick $K = J_>$ and then x is a basic feasible solution. If $|J_>| < m$, we can extend $J_>$ to an m -element subset K by adding $m - |J_>|$ column indices so that the columns of A_K are linearly independent, which is possible since A has rank m . \square

Next we prove that if a linear program in standard form has any feasible solution x_0 and is bounded above, then it has some basic feasible solution \tilde{x} which is as good as x_0 , in the sense that $c\tilde{x} \geq cx_0$.

Proposition 45.3. *Let (P_2) be any standard linear program with objective function cx , where $Ax = b$ and A is an $m \times n$ matrix of rank m . If (P_2) is bounded above and if x_0 is some feasible solution of (P_2) , then there is some basic feasible solution \tilde{x} such that $c\tilde{x} \geq cx_0$.*

Proof. Among the feasible solutions x such that $cx \geq cx_0$ (x_0 is one of them) pick one with the maximum number of coordinates x_j equal to 0, say \tilde{x} . Let

$$K = J_> = \{j \in \{1, \dots, n\} \mid \tilde{x}_j > 0\}$$

and let $s = |K|$. We claim that \tilde{x} is a basic feasible solution, and by construction $c\tilde{x} \geq cx_0$.

If the columns of A_K are linearly independent, then by Proposition 45.2 we know that \tilde{x} is a basic feasible solution and we are done.

Otherwise, the columns of A_K are linearly dependent, so there is some nonzero vector $v = (v_1, \dots, v_s)$ such that $A_K v = 0$. Let $w \in \mathbb{R}^n$ be the vector obtained by extending v by setting $w_j = 0$ for all $j \notin K$. By construction,

$$Aw = A_K v = 0.$$

We will derive a contradiction by exhibiting a feasible solution $x(t_0)$ such that $cx(t_0) \geq cx_0$ with more zero coordinates than \tilde{x} .

For this we claim that we may assume that w satisfies the following two conditions:

- (1) $cw \geq 0$.
- (2) There is some $j \in K$ such that $w_j < 0$.

If $cw = 0$ and if Condition (2) fails, since $w \neq 0$, we have $w_j > 0$ for some $j \in K$, in which case we can use $-w$, for which $w_j < 0$.

If $cw < 0$, then $c(-w) > 0$, so we may assume that $cw > 0$. If $w_j > 0$ for all $j \in K$, since \tilde{x} is feasible, $\tilde{x} \geq 0$, and so $x(t) = \tilde{x} + tw \geq 0$ for all $t \geq 0$. Furthermore, since $Aw = 0$ and \tilde{x} is feasible, we have

$$Ax(t) = A\tilde{x} + tAw = b,$$

and thus $x(t)$ is feasible for all $t \geq 0$. We also have

$$cx(t) = c\tilde{x} + tcw.$$

Since $cw > 0$, as $t > 0$ goes to infinity the objective function $cx(t)$ also tends to infinity, contradicting the fact that it is bounded above. Therefore, some w satisfying Conditions (1) and (2) above must exist.

We show that there is some $t_0 > 0$ such that $cx(t_0) \geq cx_0$ and $x(t_0) = \tilde{x} + t_0w$ is feasible, yet $x(t_0)$ has more zero coordinates than \tilde{x} , a contradiction.

Since $x(t) = \tilde{x} + tw$, we have

$$x(t)_i = \tilde{x}_i + tw_i,$$

so if we let $I = \{i \in \{1, \dots, n\} \mid w_i < 0\} \subseteq K$, which is nonempty since w satisfies Condition (2) above, if we pick

$$t_0 = \min_{i \in I} \left\{ \frac{-\tilde{x}_i}{w_i} \right\},$$

then $t_0 > 0$, because $w_i < 0$ for all $i \in I$, and by definition of K we have $\tilde{x}_i > 0$ for all $i \in K$. By the definition of $t_0 > 0$ and since $\tilde{x} \geq 0$, we have

$$x(t_0)_j = \tilde{x}_j + t_0w_j \geq 0 \quad \text{for all } j \in K,$$

so $x(t_0) \geq 0$, and $x(t_0)_i = 0$ for some $i \in I$. Since $Ax(t_0) = b$ (for any t), $x(t_0)$ is a feasible solution,

$$cx(t_0) = c\tilde{x} + t_0cw \geq cx_0 + t_0cw \geq cx_0,$$

and $x(t_0)_i = 0$ for some $i \in I$, we see that $x(t_0)$ has more zero coordinates than \tilde{x} , a contradiction. \square

Proposition 45.3 implies the following important result.

Theorem 45.4. *Let (P_2) be any standard linear program with objective function cx , where $Ax = b$ and A is an $m \times n$ matrix of rank m . If (P_2) has some feasible solution and if it is bounded above, then some basic feasible solution \tilde{x} is an optimal solution of (P_2) .*

Proof. By Proposition 45.3, for any feasible solution x there is some basic feasible solution \tilde{x} such that $cx \leq c\tilde{x}$. But there are only finitely many basic feasible solutions, so one of them has to yield the maximum of the objective function. \square

Geometrically, basic solutions are exactly the vertices of the polyhedron $\mathcal{P}(A, b)$, a notion that we now define.

Definition 45.8. Given an \mathcal{H} -polyhedron $\mathcal{P} \subseteq \mathbb{R}^n$, a *vertex* of \mathcal{P} is a point $v \in \mathcal{P}$ with property that there is some nonzero linear form $c \in (\mathbb{R}^n)^*$ and some $\mu \in \mathbb{R}$, such that v is the unique point of \mathcal{P} for which the map $x \mapsto cx$ has the maximum value μ ; that is, $cy < cv = \mu$ for all $y \in \mathcal{P} - \{v\}$. Geometrically, this means that the hyperplane of equation $cy = \mu$ touches \mathcal{P} exactly at v . More generally, a convex subset F of \mathcal{P} is a *k-dimensional face* of \mathcal{P} if F has dimension k and if there is some affine form $\varphi(x) = cx - \mu$ such that $cy = \mu$ for all $y \in F$, and $cy < \mu$ for all $y \in \mathcal{P} - F$. A 1-dimensional face is called an *edge*.

The concept of a vertex is illustrated in Figure 45.4, while the concept of an edge is illustrated in Figure 45.5.

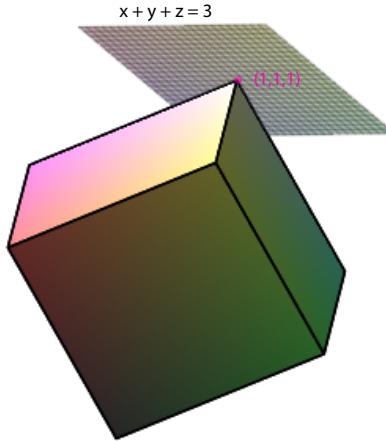

Figure 45.4: The cube centered at the origin with diagonal through $(-1, -1, -1)$ and $(1, 1, 1)$ has eight vertices. The vertex $(1, 1, 1)$ is associated with the linear form $x + y + z = 3$.

Since a k -dimensional face F of \mathcal{P} is equal to the intersection of the hyperplane $H(\varphi)$ of equation $cx = \mu$ with \mathcal{P} , it is indeed convex and the notion of dimension makes sense.

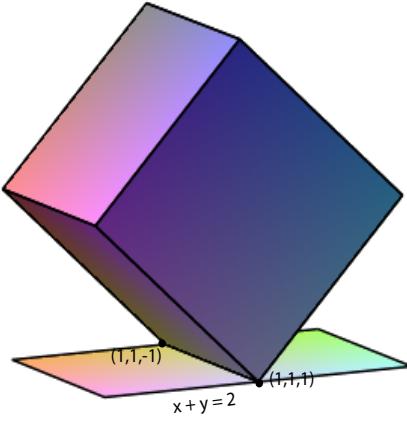

Figure 45.5: The cube centered at the origin with diagonal through $(-1, -1, -1)$ and $(1, 1, 1)$ has twelve edges. The edge from $(1, 1, -1)$ to $(1, 1, 1)$ is associated with the linear form $x + y = 2$.

Observe that a 0-dimensional face of \mathcal{P} is a vertex. If \mathcal{P} has dimension d , then the $(d - 1)$ -dimensional faces of \mathcal{P} are called its *facets*.

If (P) is a linear program in standard form, then its basic feasible solutions are exactly the vertices of the polyhedron $\mathcal{P}(A, b)$. To prove this fact we need the following simple proposition

Proposition 45.5. *Let $Ax = b$ be a linear system where A is an $m \times n$ matrix of rank m . For any subset $K \subseteq \{1, \dots, n\}$ of size m , if A_K is invertible, then there is at most one basic feasible solution $x \in \mathbb{R}^n$ with $x_j = 0$ for all $j \notin K$ (of course, $x \geq 0$)*

Proof. In order for x to be feasible we must have $Ax = b$. Write $N = \{1, \dots, n\} - K$, x_K for the vector consisting of the coordinates of x with indices in K , and x_N for the vector consisting of the coordinates of x with indices in N . Then

$$Ax = A_K x_K + A_N x_N = b.$$

In order for x to be a basic feasible solution we must have $x_N = 0$, so

$$A_K x_K = b.$$

Since by hypothesis A_K is invertible, $x_K = A_K^{-1}b$ is uniquely determined. If $x_K \geq 0$ then x is a basic feasible solution, otherwise it is not. This proves that there is at most one basic feasible solution $x \in \mathbb{R}^n$ with $x_j = 0$ for all $j \notin K$. \square

Theorem 45.6. *Let (P) be a linear program in standard form, where $Ax = b$ and A is an $m \times n$ matrix of rank m . For every $v \in \mathcal{P}(A, b)$, the following conditions are equivalent:*

- (1) v is a vertex of the Polyhedron $\mathcal{P}(A, b)$.
- (2) v is a basic feasible solution of the Linear Program (P) .

Proof. First, assume that v is a vertex of $\mathcal{P}(A, b)$, and let $\varphi(x) = cx - \mu$ be a linear form such that $cy < \mu$ for all $y \in \mathcal{P}(A, b)$ and $c v = \mu$. This means that v is the unique point of $\mathcal{P}(A, b)$ for which the objective function $x \mapsto cx$ has the maximum value μ on $\mathcal{P}(A, b)$, so by Theorem 45.4, since this maximum is achieved by some basic feasible solution, by uniqueness v must be a basic feasible solution.

Conversely, suppose v is a basic feasible solution of (P) corresponding to a subset $K \subseteq \{1, \dots, n\}$ of size m . Let $\hat{c} \in (\mathbb{R}^n)^*$ be the linear form defined by

$$\hat{c}_j = \begin{cases} 0 & \text{if } j \in K \\ -1 & \text{if } j \notin K. \end{cases}$$

By construction $\hat{c}v = 0$ and $\hat{c}x \leq 0$ for any $x \geq 0$, hence the function $x \mapsto \hat{c}x$ on $\mathcal{P}(A, b)$ has a maximum at v . Furthermore, $\hat{c}x < 0$ for any $x \geq 0$ such that $x_j > 0$ for some $j \notin K$. However, by Proposition 45.5, the vector v is the only basic feasible solution such that $v_j = 0$ for all $j \notin K$, and therefore v is the only point of $\mathcal{P}(A, b)$ maximizing the function $x \mapsto \hat{c}x$, so it is a vertex. \square

In theory, to find an optimal solution we try all $\binom{n}{m}$ possible m -elements subsets K of $\{1, \dots, n\}$ and solve for the corresponding unique solution x_K of $A_K x = b$. Then we check whether such a solution satisfies $x_K \geq 0$, compute cx_K , and return some feasible x_K for which the objective function is maximum. This is a totally impractical algorithm.

A practical algorithm is the *simplex algorithm*. Basically, the simplex algorithm tries to “climb” in the polyhedron $\mathcal{P}(A, b)$ from vertex to vertex along edges (using basic feasible solutions), trying to maximize the objective function. We present the simplex algorithm in the next chapter. The reader may also consult texts on linear programming. In particular, we recommend Matousek and Gardner [123], Chvatal [40], Papadimitriou and Steiglitz [134], Bertsimas and Tsitsiklis [21], Ciarlet [41], Schrijver [148], and Vanderbei [181].

Observe that Theorem 45.4 asserts that if a Linear Program (P) in standard form (where $Ax = b$ and A is an $m \times n$ matrix of rank m) has some feasible solution and is bounded above, then some basic feasible solution is an optimal solution. By Theorem 45.6, the polyhedron $\mathcal{P}(A, b)$ must have some vertex.

But suppose we only know that $\mathcal{P}(A, b)$ is nonempty; that is, we don’t know that the objective function cx is bounded above. Does $\mathcal{P}(A, b)$ have some vertex?

The answer to the above question is *yes*, and this is important because the simplex algorithm needs an initial basic feasible solution to get started. Here we prove that if $\mathcal{P}(A, b)$ is nonempty, then it must contain a vertex. This proof still doesn’t constructively yield a vertex, but we will see in the next chapter that the simplex algorithm always finds a vertex if there is one (provided that we use a pivot rule that prevents cycling).

Theorem 45.7. Let (P) be a linear program in standard form, where $Ax = b$ and A is an $m \times n$ matrix of rank m . If $\mathcal{P}(A, b)$ is nonempty (there is a feasible solution), then $\mathcal{P}(A, b)$ has some vertex; equivalently, (P) has some basic feasible solution.

Proof. The proof relies on a trick, which is to add slack variables x_{n+1}, \dots, x_{n+m} and use the new objective function $-(x_{n+1} + \dots + x_{n+m})$.

If we let \widehat{A} be the $m \times (m+n)$ -matrix, and x, \bar{x} , and \widehat{x} be the vectors given by

$$\widehat{A} = (A \quad I_m), \quad x = \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix} \in \mathbb{R}^n, \quad \bar{x} = \begin{pmatrix} x_{n+1} \\ \vdots \\ x_{n+m} \end{pmatrix} \in \mathbb{R}^m, \quad \widehat{x} = \begin{pmatrix} x \\ \bar{x} \end{pmatrix} \in \mathbb{R}^{n+m},$$

then consider the Linear Program (\widehat{P}) in standard form

$$\begin{aligned} &\text{maximize} && -(x_{n+1} + \dots + x_{n+m}) \\ &\text{subject to} && \widehat{A}\widehat{x} = b \text{ and } \widehat{x} \geq 0. \end{aligned}$$

Since $x_i \geq 0$ for all i , the objective function $-(x_{n+1} + \dots + x_{n+m})$ is bounded above by 0. The system $\widehat{A}\widehat{x} = b$ is equivalent to the system

$$Ax + \bar{x} = b,$$

so for every feasible solution $u \in \mathcal{P}(A, b)$, since $Au = b$, the vector $(u, 0_m)$ is also a feasible solution of (\widehat{P}) , in fact an optimal solution since the value of the objective function $-(x_{n+1} + \dots + x_{n+m})$ for $\bar{x} = 0$ is 0. By Proposition 45.3, the linear program (\widehat{P}) has some basic feasible solution (u^*, w^*) for which the value of the objective function is greater than or equal to the value of the objective function for $(u, 0_m)$, and since $(u, 0_m)$ is an optimal solution, (u^*, w^*) is also an optimal solution of (\widehat{P}) . This implies that $w^* = 0$, since otherwise the objective function $-(x_{n+1} + \dots + x_{n+m})$ would have a strictly negative value.

Therefore, $(u^*, 0_m)$ is a basic feasible solution of (\widehat{P}) , and thus the columns corresponding to nonzero components of u^* are linearly independent. Some of the coordinates of u^* could be equal to 0, but since A has rank m we can add columns of A to obtain a basis K associated with u^* , and u^* is indeed a basic feasible solution of (P) . \square

The definition of a basic feasible solution can be adapted to linear programs where the constraints are of the form $Ax \leq b$, $x \geq 0$; see Matousek and Gardner [123] (Chapter 4, Section 4, Definition 4.4.2).

The most general type of linear program allows constraints of the form $a_i x \geq b_i$ or $a_i x = b_i$ besides constraints of the form $a_i x \leq b_i$. The variables x_i may also take negative values. It is always possible to convert such programs to the type considered in Definition 45.1. We proceed as follows.

Every constraint $a_i x \geq b_i$ is replaced by the constraint $-a_i x \leq -b_i$. Every equality constraint $a_i x = b_i$ is replaced by the two constraints $a_i x \leq b_i$ and $-a_i x \leq -b_i$.

If there are n variables x_i , we create n new variables y_i and n new variables z_i and replace every variable x_i by $y_i - z_i$. We also add the $2n$ constraints $y_i \geq 0$ and $z_i \geq 0$. If the constraints are given by the inequalities $Ax \leq b$, we now have constraints given by

$$(A \quad -A) \begin{pmatrix} y \\ z \end{pmatrix} \leq b, \quad y \geq 0, z \geq 0.$$

We replace the objective function cx by $cy - cz$.

Remark: We also showed that we can replace the inequality constraints $Ax \leq b$ by equality constraints $Ax = b$, by adding slack variables constrained to be nonnegative.

45.3 Summary

The main concepts and results of this chapter are listed below:

- Linear program.
- Objective function, constraints.
- Feasible solution.
- Bounded and unbounded linear programs.
- Optimal solution, optimum.
- Slack variables, linear program in standard form.
- Basic feasible solution.
- Basis of a variable.
- Basic, nonbasic index, basic, nonbasic variable.
- Vertex, face, edge, facet.

45.4 Problems

Problem 45.1. Convert the following program to standard form:

$$\begin{aligned} & \text{maximize} && x_1 + x_2 \\ & \text{subject to} && \\ & && x_2 - x_1 \leq 1 \\ & && x_1 + 6x_2 \leq 15 \\ & && -4x_1 + x_2 \geq 10. \end{aligned}$$

Problem 45.2. Convert the following program to standard form:

$$\begin{aligned} & \text{maximize} && 3x_1 - 2x_2 \\ & \text{subject to} && \\ & && 2x_1 - x_2 \leq 4 \\ & && x_1 + 3x_2 \geq 5 \\ & && x_2 \geq 0. \end{aligned}$$

Problem 45.3. The notion of basic feasible solution for linear programs where the constraints are of the form $Ax \leq b$, $x \geq 0$ is defined as follows. A basic feasible solution of a (general) linear program with n variables is a feasible solution for which some n linearly independent constraints hold with equality.

Prove that the definition of a basic feasible solution for linear programs in standard form is a special case of the above definition.

Problem 45.4. Consider the linear program

$$\begin{aligned} & \text{maximize} && x_1 + x_2 \\ & \text{subject to} && \\ & && x_1 + x_2 \leq 1. \end{aligned}$$

Show that none of the optimal solutions are basic.

Problem 45.5. The *standard n-simplex* is the subset Δ^n of \mathbb{R}^{n+1} given by

$$\Delta^n = \{(x_1, \dots, x_{n+1}) \in \mathbb{R}^{n+1} \mid x_1 + \dots + x_{n+1} = 1, x_i \geq 0, 1 \leq i \leq n+1\}.$$

- (1) Prove that Δ^n is convex and that it is the convex hull of the $n+1$ vectors e_1, \dots, e_{n+1} , where e_i is the i th canonical unit basis vector, $i = 1, \dots, n+1$.
- (2) Prove that Δ^n is the intersection of $n+1$ half spaces and determine the hyperplanes defining these half-spaces.

Remark: The volume under the standard simplex Δ^n is $1/(n+1)!$.

Problem 45.6. The n -dimensional *cross-polytope* is the subset XP_n of \mathbb{R}^n given by

$$XP_n = \{(x_1, \dots, x_n) \in \mathbb{R}^n \mid |x_1| + \dots + |x_n| \leq 1\}.$$

- (1) Prove that XP_n is convex and that it is the convex hull of the $2n$ vectors $\pm e_i$, where e_i is the i th canonical unit basis vector, $i = 1, \dots, n$.
- (2) Prove that XP_n is the intersection of 2^n half spaces and determine the hyperplanes defining these half-spaces.

Remark: The volume of XP_n is $2^n/n!$.

Problem 45.7. The n -dimensional *hypercube* is the subset C_n of \mathbb{R}^n given by

$$C_n = \{(x_1, \dots, x_n) \in \mathbb{R}^n \mid |x_i| \leq 1, 1 \leq i \leq n\}.$$

- (1) Prove that C_n is convex and that it is the convex hull of the 2^n vectors $(\pm 1, \dots, \pm 1)$, $i = 1, \dots, n$.
- (2) Prove that C_n is the intersection of $2n$ half spaces and determine the hyperplanes defining these half-spaces.

Remark: The volume of C_n is 2^n .

Chapter 46

The Simplex Algorithm

46.1 The Idea Behind the Simplex Algorithm

The simplex algorithm, due to Dantzig, applies to a linear program (P) in standard form, where the constraints are given by $Ax = b$ and $x \geq 0$, with A a $m \times n$ matrix of rank m , and with an objective function $x \mapsto cx$. This algorithm either reports that (P) has no feasible solution, or that (P) is unbounded, or yields an optimal solution. Geometrically, the algorithm climbs from vertex to vertex in the polyhedron $\mathcal{P}(A, b)$, trying to improve the value of the objective function. Since vertices correspond to basic feasible solutions, the simplex algorithm actually works with basic feasible solutions.

Recall that a basic feasible solution x is a feasible solution for which there is a subset $K \subseteq \{1, \dots, n\}$ of size m such that the matrix A_K consisting of the columns of A whose indices belong to K are linearly independent, and that $x_j = 0$ for all $j \notin K$. We also let $J_>(x)$ be the set of indices

$$J_>(x) = \{j \in \{1, \dots, n\} \mid x_j > 0\},$$

so for a basic feasible solution x associated with K , we have $J_>(x) \subseteq K$. In fact, by Proposition 45.2, a feasible solution x is a basic feasible solution iff the columns of $A_{J_>(x)}$ are linearly independent.

If $J_>(x)$ had cardinality m for all basic feasible solutions x , then the simplex algorithm would make progress at every step, in the sense that it would strictly increase the value of the objective function. Unfortunately, it is possible that $|J_>(x)| < m$ for certain basic feasible solutions, and in this case a step of the simplex algorithm may not increase the value of the objective function. Worse, in rare cases, it is possible that the algorithm enters an infinite loop. This phenomenon called *cycling* can be detected, but in this case the algorithm fails to give a conclusive answer.

Fortunately, there are ways of preventing the simplex algorithm from cycling (for example, Bland's rule discussed later), although proving that these rules work correctly is quite involved.

The potential “bad” behavior of a basic feasible solution is recorded in the following definition.

Definition 46.1. Given a Linear Program (P) in standard form where the constraints are given by $Ax = b$ and $x \geq 0$, with A an $m \times n$ matrix of rank m , a basic feasible solution x is *degenerate* if $|J_>(x)| < m$, otherwise it is *nondegenerate*.

The origin 0_n , if it is a basic feasible solution, is degenerate. For a less trivial example, $x = (0, 0, 0, 2)$ is a degenerate basic feasible solution of the following linear program in which $m = 2$ and $n = 4$.

Example 46.1.

$$\begin{aligned} & \text{maximize} && x_2 \\ & \text{subject to} && \\ & && -x_1 + x_2 + x_3 = 0 \\ & && x_1 + x_4 = 2 \\ & && x_1 \geq 0, x_2 \geq 0, x_3 \geq 0, x_4 \geq 0. \end{aligned}$$

The matrix A and the vector b are given by

$$A = \begin{pmatrix} -1 & 1 & 1 & 0 \\ 1 & 0 & 0 & 1 \end{pmatrix}, \quad b = \begin{pmatrix} 0 \\ 2 \end{pmatrix},$$

and if $x = (0, 0, 0, 2)$, then $J_>(x) = \{4\}$. There are two ways of forming a set of two linearly independent columns of A containing the fourth column.

Given a basic feasible solution x associated with a subset K of size m , since the columns of the matrix A_K are linearly independent, by abuse of language we call the columns of A_K a *basis* of x .

If u is a vertex of (P), that is, a basic feasible solution of (P) associated with a basis K (of size m), in “normal mode,” the simplex algorithm tries to move along an edge from the vertex u to an adjacent vertex v (with $u, v \in \mathcal{P}(A, b) \subseteq \mathbb{R}^n$) corresponding to a basic feasible solution whose basis is obtained by replacing one of the basic vectors A^k with $k \in K$ by another nonbasic vector A^j for some $j \notin K$, in such a way that the value of the objective function is increased.

Let us demonstrate this process on an example.

Example 46.2. Let (P) be the following linear program in standard form.

$$\begin{aligned} & \text{maximize} && x_1 + x_2 \\ & \text{subject to} && \\ & && -x_1 + x_2 + x_3 = 1 \\ & && x_1 + x_4 = 3 \\ & && x_2 + x_5 = 2 \\ & && x_1 \geq 0, x_2 \geq 0, x_3 \geq 0, x_4 \geq 0, x_5 \geq 0. \end{aligned}$$

The matrix A and the vector b are given by

$$A = \begin{pmatrix} -1 & 1 & 1 & 0 & 0 \\ 1 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 1 \end{pmatrix}, \quad b = \begin{pmatrix} 1 \\ 3 \\ 2 \end{pmatrix}.$$

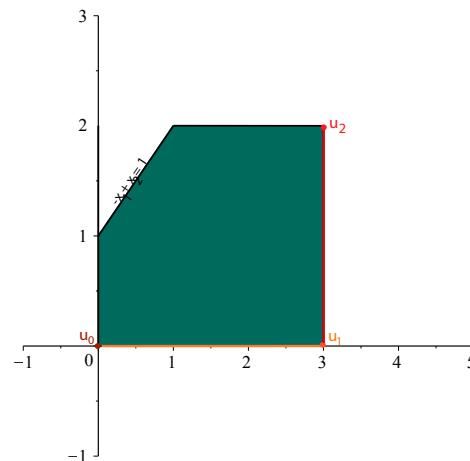

Figure 46.1: The planar \mathcal{H} -polyhedron associated with Example 46.2. The initial basic feasible solution is the origin. The simplex algorithm first moves along the horizontal orange line to feasible solution at vertex u_1 . It then moves along the vertical red line to obtain the optimal feasible solution u_2 .

The vector $u_0 = (0, 0, 1, 3, 2)$ corresponding to the basis $K = \{3, 4, 5\}$ is a basic feasible solution, and the corresponding value of the objective function is $0 + 0 = 0$. Since the columns (A^3, A^4, A^5) corresponding to $K = \{3, 4, 5\}$ are linearly independent we can express A^1 and A^2 as

$$\begin{aligned} A^1 &= -A^3 + A^4 \\ A^2 &= A^3 + A^5. \end{aligned}$$

Since

$$1A^3 + 3A^4 + 2A^5 = Au_0 = b,$$

for any $\theta \in \mathbb{R}$, we have

$$\begin{aligned} b &= 1A^3 + 3A^4 + 2A^5 - \theta A^1 + \theta A^1 \\ &= 1A^3 + 3A^4 + 2A^5 - \theta(-A^3 + A^4) + \theta A^1 \\ &= \theta A^1 + (1 + \theta)A^3 + (3 - \theta)A^4 + 2A^5, \end{aligned}$$

and

$$\begin{aligned} b &= 1A^3 + 3A^4 + 2A^5 - \theta A^2 + \theta A^2 \\ &= 1A^3 + 3A^4 + 2A^5 - \theta(A^3 + A^5) + \theta A^2 \\ &= \theta A^2 + (1 - \theta)A^3 + 3A^4 + (2 - \theta)A^5. \end{aligned}$$

In the first case, the vector $(\theta, 0, 1 + \theta, 3 - \theta, 2)$ is a feasible solution iff $0 \leq \theta \leq 3$, and the new value of the objective function is θ .

In the second case, the vector $(0, \theta, 1 - \theta, 3, 2 - \theta, 1)$ is a feasible solution iff $0 \leq \theta \leq 1$, and the new value of the objective function is also θ .

Consider the first case. It is natural to ask whether we can get another vertex and increase the objective function by setting to zero one of the coordinates of $(\theta, 0, 1 + \theta, 3 - \theta, 2)$, in this case the fourth one, by picking $\theta = 3$. This yields the feasible solution $(3, 0, 4, 0, 2)$, which corresponds to the basis (A^1, A^3, A^5) , and so is indeed a basic feasible solution, with an improved value of the objective function equal to 3. Note that A^4 left the basis (A^3, A^4, A^5) and A^1 entered the new basis (A^1, A^3, A^5) .

We can now express A^2 and A^4 in terms of the basis (A^1, A^3, A^5) , which is easy to do since we already have A^1 and A^2 in term of (A^3, A^4, A^5) , and A^1 and A^4 are swapped. Such a step is called a *pivoting step*. We obtain

$$\begin{aligned} A^2 &= A^3 + A^5 \\ A^4 &= A^1 + A^3. \end{aligned}$$

Then we repeat the process with $u_1 = (3, 0, 4, 0, 2)$ and the basis (A^1, A^3, A^5) . We have

$$\begin{aligned} b &= 3A^1 + 4A^3 + 2A^5 - \theta A^2 + \theta A^2 \\ &= 3A^1 + 4A^3 + 2A^5 - \theta(A^3 + A^5) + \theta A^2 \\ &= 3A^1 + \theta A^2 + (4 - \theta)A^3 + (2 - \theta)A^5, \end{aligned}$$

and

$$\begin{aligned} b &= 3A^1 + 4A^3 + 2A^5 - \theta A^4 + \theta A^4 \\ &= 3A^1 + 4A^3 + 2A^5 - \theta(A^1 + A^3) + \theta A^4 \\ &= (3 - \theta)A^1 + (4 - \theta)A^3 + \theta A^4 + 2A^5. \end{aligned}$$

In the first case, the point $(3, \theta, 4 - \theta, 0, 2 - \theta)$ is a feasible solution iff $0 \leq \theta \leq 2$, and the new value of the objective function is $3 + \theta$. In the second case, the point $(3 - \theta, 0, 4 - \theta, \theta, 2)$ is a feasible solution iff $0 \leq \theta \leq 3$, and the new value of the objective function is $3 - \theta$. To increase the objective function, we must choose the first case and we pick $\theta = 2$. Then we get the feasible solution $u_2 = (3, 2, 2, 0, 0)$, which corresponds to the basis (A^1, A^2, A^3) , and thus is a basic feasible solution. The new value of the objective function is 5.

Next we express A^4 and A^5 in terms of the basis (A^1, A^2, A^3) . Again this is easy to do since we just swapped A^5 and A^2 (a pivoting step), and we get

$$\begin{aligned} A^5 &= A^2 - A^3 \\ A^4 &= A^1 + A^3. \end{aligned}$$

We repeat the process with $u_2 = (3, 2, 2, 0, 0)$ and the basis (A^1, A^2, A^3) . We have

$$\begin{aligned} b &= 3A^1 + 2A^2 + 2A^3 - \theta A^4 + \theta A^4 \\ &= 3A^1 + 2A^2 + 2A^3 - \theta(A^1 + A^3) + \theta A^4 \\ &= (3 - \theta)A^1 + 2A^2 + (2 - \theta)A^3 + \theta A^4, \end{aligned}$$

and

$$\begin{aligned} b &= 3A^1 + 2A^2 + 2A^3 - \theta A^5 + \theta A^5 \\ &= 3A^1 + 2A^2 + 2A^3 - \theta(A^2 - A^3) + \theta A^5 \\ &= 3A^1 + (2 - \theta)A^2 + (2 + \theta)A^3 + \theta A^5. \end{aligned}$$

In the first case, the point $(3 - \theta, 2, 2 - \theta, \theta, 0)$ is a feasible solution iff $0 \leq \theta \leq 2$, and the value of the objective function is $5 - \theta$. In the second case, the point $(3, 2 - \theta, 2 + \theta, 0, \theta)$ is a feasible solution iff $0 \leq \theta \leq 2$, and the value of the objective function is also $5 - \theta$. Since we must have $\theta \geq 0$ to have a feasible solution, there is no way to increase the objective function. In this situation, it turns out that we have reached an optimal solution, in our case $u_2 = (3, 2, 2, 0, 0)$, with the maximum of the objective function equal to 5.

We could also have applied the simplex algorithm to the vertex $u_0 = (0, 0, 1, 3, 2)$ and to the vector $(0, \theta, 1 - \theta, 3, 2 - \theta, 1)$, which is a feasible solution iff $0 \leq \theta \leq 1$, with new value of the objective function θ . By picking $\theta = 1$, we obtain the feasible solution $(0, 1, 0, 3, 1)$, corresponding to the basis (A^2, A^4, A^5) , which is indeed a vertex. The new value of the objective function is 1. Then we express A^1 and A^3 in terms the basis (A^2, A^4, A^5) obtaining

$$\begin{aligned} A^1 &= A^4 - A^3 \\ A^3 &= A^2 - A^5, \end{aligned}$$

and repeat the process with $(0, 1, 0, 3, 1)$ and the basis (A^2, A^4, A^5) . After three more steps we will reach the optimal solution $u_2 = (3, 2, 2, 0, 0)$.

Let us go back to the linear program of Example 46.1 with objective function x_2 and where the matrix A and the vector b are given by

$$A = \begin{pmatrix} -1 & 1 & 1 & 0 \\ 1 & 0 & 0 & 1 \end{pmatrix}, \quad b = \begin{pmatrix} 0 \\ 2 \end{pmatrix}.$$

Recall that $u_0 = (0, 0, 0, 2)$ is a degenerate basic feasible solution, and the objective function has the value 0. See Figure 46.2 for a planar picture of the \mathcal{H} -polyhedron associated with Example 46.1.

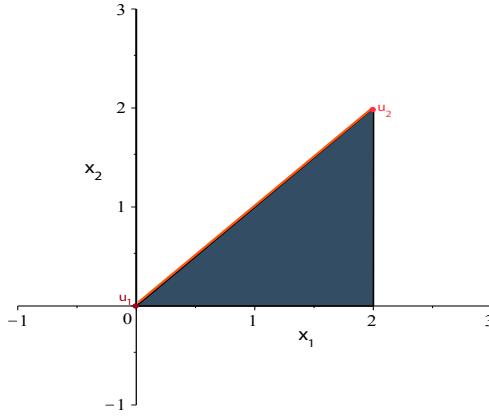

Figure 46.2: The planar \mathcal{H} -polyhedron associated with Example 46.1. The initial basic feasible solution is the origin. The simplex algorithm moves along the slanted orange line to the apex of the triangle.

Pick the basis (A^3, A^4) . Then we have

$$\begin{aligned} A^1 &= -A^3 + A^4 \\ A^2 &= A^3, \end{aligned}$$

and we get

$$\begin{aligned} b &= 2A^4 - \theta A^1 + \theta A^2 \\ &= 2A^4 - \theta(-A^3 + A^4) + \theta A^3 \\ &= \theta A^1 + \theta A^3 + (2 - \theta)A^4, \end{aligned}$$

and

$$\begin{aligned} b &= 2A^4 - \theta A^2 + \theta A^1 \\ &= 2A^4 - \theta A^3 + \theta A^2 \\ &= \theta A^2 - \theta A^3 + 2A^4. \end{aligned}$$

In the first case, the point $(\theta, 0, \theta, 2 - \theta)$ is a feasible solution iff $0 \leq \theta \leq 2$, and the value of the objective function is 0, and in the second case the point $(0, \theta, -\theta, 2)$ is a feasible solution iff $\theta = 0$, and the value of the objective function is θ . However, since we must have $\theta = 0$ in the second case, there is no way to increase the objective function either.

It turns out that in order to make the cases considered by the simplex algorithm as mutually exclusive as possible, since in the second case the coefficient of θ in the value of the objective function is nonzero, namely 1, we should choose the second case. We must pick $\theta = 0$, but we can swap the vectors A^3 and A^2 (because A^2 is coming in and A^3 has the coefficient $-\theta$, which is the reason why θ must be zero), and we obtain the basic feasible solution $u_1 = (0, 0, 0, 2)$ with the new basis (A^2, A^4) . Note that this basic feasible solution corresponds to the same vertex $(0, 0, 0, 2)$ as before, but the basis has changed. The vectors A^1 and A^3 can be expressed in terms of the basis (A^2, A^4) as

$$\begin{aligned} A^1 &= -A^2 + A^4 \\ A^3 &= A^2. \end{aligned}$$

We now repeat the procedure with $u_1 = (0, 0, 0, 2)$ and the basis (A^2, A^4) , and we get

$$\begin{aligned} b &= 2A^4 - \theta A^1 + \theta A^3 \\ &= 2A^4 - \theta(-A^2 + A^4) + \theta A^1 \\ &= \theta A^1 + \theta A^2 + (2 - \theta)A^4, \end{aligned}$$

and

$$\begin{aligned} b &= 2A^4 - \theta A^3 + \theta A^1 \\ &= 2A^4 - \theta A^2 + \theta A^3 \\ &= -\theta A^2 + \theta A^3 + 2A^4. \end{aligned}$$

In the first case, the point $(\theta, \theta, 0, 2 - \theta)$ is a feasible solution iff $0 \leq \theta \leq 2$ and the value of the objective function is θ , and in the second case the point $(0, -\theta, \theta, 2)$ is a feasible solution iff $\theta = 0$ and the value of the objective function is θ . In order to increase the objective function we must choose the first case and pick $\theta = 2$. We obtain the feasible solution $u_2 = (2, 2, 0, 0)$ whose corresponding basis is (A^1, A^2) and the value of the objective function is 2.

The vectors A^3 and A^4 are expressed in terms of the basis (A^1, A^2) as

$$\begin{aligned} A^3 &= A^2 \\ A^4 &= A^1 + A^3, \end{aligned}$$

and we repeat the procedure with $u_2 = (2, 2, 0, 0)$ and the basis (A^1, A^2) . We get

$$\begin{aligned} b &= 2A^1 + 2A^2 - \theta A^3 + \theta A^4 \\ &= 2A^1 + 2A^2 - \theta A^2 + \theta A^3 \\ &= 2A^1 + (2 - \theta)A^2 + \theta A^3, \end{aligned}$$

and

$$\begin{aligned} b &= 2A^1 + 2A^2 - \theta A^4 + \theta A^4 \\ &= 2A^1 + 2A^2 - \theta(A^1 + A^3) + \theta A^4 \\ &= (2 - \theta)A^1 + 2A^2 - \theta A^3 + \theta A^4. \end{aligned}$$

In the first case, the point $(2, 2 - \theta, 0, \theta)$ is a feasible solution iff $0 \leq \theta \leq 2$ and the value of the objective function is $2 - \theta$, and in the second case, the point $(2 - \theta, 2, -\theta, \theta)$ is a feasible solution iff $\theta = 0$ and the value of the objective function is 2. This time there is no way to improve the objective function and we have reached an optimal solution $u_2 = (2, 2, 0, 0)$ with the maximum of the objective function equal to 2.

Let us now consider an example of an unbounded linear program.

Example 46.3. Let (P) be the following linear program in standard form.

maximize x_1

subject to

$$\begin{aligned} x_1 - x_2 + x_3 &= 1 \\ -x_1 + x_2 + x_4 &= 2 \\ x_1 \geq 0, x_2 \geq 0, x_3 \geq 0, x_4 \geq 0. \end{aligned}$$

The matrix A and the vector b are given by

$$A = \begin{pmatrix} 1 & -1 & 1 & 0 \\ -1 & 1 & 0 & 1 \end{pmatrix}, \quad b = \begin{pmatrix} 1 \\ 2 \end{pmatrix}.$$

The vector $u_0 = (0, 0, 1, 2)$ corresponding to the basis $K = \{3, 4\}$ is a basic feasible solution, and the corresponding value of the objective function is 0. The vectors A^1 and A^2 are expressed in terms of the basis (A^3, A^4) by

$$\begin{aligned} A^1 &= A^3 - A^4 \\ A^2 &= -A^3 + A^4. \end{aligned}$$

Starting with $u_0 = (0, 0, 1, 2)$, we get

$$\begin{aligned} b &= A^3 + 2A^4 - \theta A^1 + \theta A^1 \\ &= A^3 + 2A^4 - \theta(A^3 - A^4) + \theta A^1 \\ &= \theta A^1 + (1 - \theta)A^3 + (2 + \theta)A^4, \end{aligned}$$

and

$$\begin{aligned} b &= A^3 + 2A^4 - \theta A^2 + \theta A^2 \\ &= A^3 + 2A^4 - \theta(-A^3 + A^4) + \theta A^2 \\ &= \theta A^2 + (1 + \theta)A^3 + (2 - \theta)A^4. \end{aligned}$$

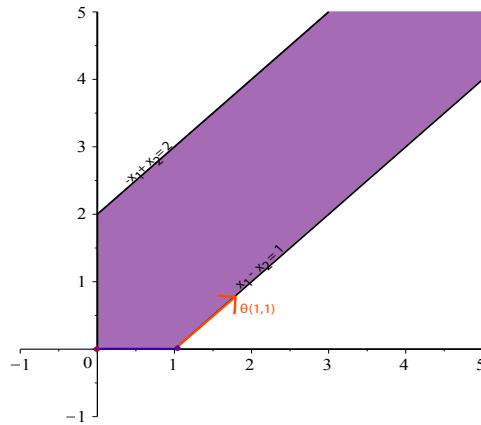

Figure 46.3: The planar \mathcal{H} -polyhedron associated with Example 46.3. The initial basic feasible solution is the origin. The simplex algorithm first moves along the horizontal indigo line to basic feasible solution at vertex $(1, 0)$. Any optimal feasible solution occurs by moving along the boundary line parameterized by the orange arrow $\theta(1, 1)$.

In the first case, the point $(\theta, 0, 1 - \theta, 2 + \theta)$ is a feasible solution iff $0 \leq \theta \leq 1$ and the value of the objective function is θ , and in the second case, the point $(0, \theta, 1 + \theta, 2 - \theta)$ is a feasible solution iff $0 \leq \theta \leq 2$ and the value of the objective function is 0. In order to increase the objective function we must choose the first case, and we pick $\theta = 1$. We get the feasible solution $u_1 = (1, 0, 0, 3)$ corresponding to the basis (A^1, A^4) , so it is a basic feasible solution, and the value of the objective function is 1.

The vectors A^2 and A^3 are given in terms of the basis (A^1, A^4) by

$$\begin{aligned} A^2 &= -A^1 \\ A^3 &= A^1 + A^4. \end{aligned}$$

Repeating the process with $u_1 = (1, 0, 0, 3)$, we get

$$\begin{aligned} b &= A^1 + 3A^4 - \theta A^2 + \theta A^2 \\ &= A^1 + 3A^4 - \theta(-A^1) + \theta A^2 \\ &= (1 + \theta)A^1 + \theta A^2 + 3A^4, \end{aligned}$$

and

$$\begin{aligned} b &= A^1 + 3A^4 - \theta A^3 + \theta A^3 \\ &= A^1 + 3A^4 - \theta(A^1 + A^4) + \theta A^3 \\ &= (1 - \theta)A^1 + \theta A^3 + (3 - \theta)A^4. \end{aligned}$$

In the first case, the point $(1 + \theta, \theta, 0, 3)$ is a feasible solution for all $\theta \geq 0$ and the value of the objective function is $1 + \theta$, and in the second case, the point $(1 - \theta, 0, \theta, 3 - \theta)$ is a feasible solution iff $0 \leq \theta \leq 1$ and the value of the objective function is $1 - \theta$. This time, we are in the situation where the points

$$(1 + \theta, \theta, 0, 3) = (1, 0, 0, 3) + \theta(1, 1, 0, 0), \quad \theta \geq 0$$

form an infinite ray in the set of feasible solutions, and the objective function $1 + \theta$ is unbounded from above on this ray. This indicates that our linear program, although feasible, is unbounded.

Let us now describe a step of the simplex algorithm in general.

46.2 The Simplex Algorithm in General

We assume that we already have an initial vertex u_0 to start from. This vertex corresponds to a basic feasible solution with basis K_0 . We will show later that it is always possible to find a basic feasible solution of a Linear Program (P) in standard form, or to detect that (P) has no feasible solution.

The idea behind the simplex algorithm is this: Given a pair (u, K) consisting of a basic feasible solution u and a basis K for u , find another pair (u^+, K^+) consisting of another basic feasible solution u^+ and a basis K^+ for u^+ , such that K^+ is obtained from K by deleting some basic index $k^- \in K$ and adding some nonbasic index $j^+ \notin K$, in such a way that the value of the objective function increases (preferably strictly). The step which consists in swapping the vectors A^{k^-} and A^{j^+} is called a *pivoting step*.

Let u be a given vertex corresponds to a basic feasible solution with basis K . Since the m vectors A^k corresponding to indices $k \in K$ are linearly independent, they form a basis, so for every nonbasic $j \notin K$, we write

$$A^j = \sum_{k \in K} \gamma_k^j A^k. \quad (*)$$

We let $\gamma_K^j \in \mathbb{R}^m$ be the vector given by $\gamma_K^j = (\gamma_k^j)_{k \in K}$. Actually, since the vector γ_K^j depends on K , to be very precise we should denote its components by $(\gamma_K^j)_k$, but to simplify notation we usually write γ_k^j instead of $(\gamma_K^j)_k$ (unless confusion arises). We will explain later how the coefficients γ_k^j can be computed efficiently.

Since u is a feasible solution we have $u \geq 0$ and $Au = b$, that is,

$$\sum_{k \in K} u_k A^k = b. \quad (**)$$

For every nonbasic $j \notin K$, a candidate for entering the basis K , we try to find a new vertex $u(\theta)$ that improves the objective function, and for this we add $-\theta A^j + \theta A^j = 0$ to b in

Equation (**) and then replace the occurrence of A^j in $-\theta A^j$ by the right hand side of Equation (*) to obtain

$$\begin{aligned} b &= \sum_{k \in K} u_k A^k - \theta A^j + \theta A^j \\ &= \sum_{k \in K} u_k A^k - \theta \left(\sum_{k \in K} \gamma_k^j A^k \right) + \theta A^j \\ &= \sum_{k \in K} (u_k - \theta \gamma_k^j) A^k + \theta A^j. \end{aligned}$$

Consequently, the vector $u(\theta)$ appearing on the right-hand side of the above equation given by

$$u(\theta)_i = \begin{cases} u_i - \theta \gamma_i^j & \text{if } i \in K \\ \theta & \text{if } i = j \\ 0 & \text{if } i \notin K \cup \{j\} \end{cases}$$

automatically satisfies the constraints $Au(\theta) = b$, and this vector is a feasible solution iff

$$\theta \geq 0 \quad \text{and} \quad u_k \geq \theta \gamma_k^j \quad \text{for all } k \in K.$$

Obviously $\theta = 0$ is a solution, and if

$$\theta^j = \min \left\{ \frac{u_k}{\gamma_k^j} \mid \gamma_k^j > 0, k \in K \right\} > 0,$$

then we have a range of feasible solutions for $0 \leq \theta \leq \theta^j$. The value of the objective function for $u(\theta)$ is

$$cu(\theta) = \sum_{k \in K} c_k (u_k - \theta \gamma_k^j) + \theta c_j = cu + \theta \left(c_j - \sum_{k \in K} \gamma_k^j c_k \right).$$

Since the potential change in the objective function is

$$\theta \left(c_j - \sum_{k \in K} \gamma_k^j c_k \right)$$

and $\theta \geq 0$, if $c_j - \sum_{k \in K} \gamma_k^j c_k \leq 0$, then the objective function can't be increased.

However, if $c_{j^+} - \sum_{k \in K} \gamma_k^{j^+} c_k > 0$ for some $j^+ \notin K$, and if $\theta^{j^+} > 0$, then the objective function can be strictly increased by choosing any $\theta > 0$ such that $\theta \leq \theta^{j^+}$, so it is natural to zero at least one coefficient of $u(\theta)$ by picking $\theta = \theta^{j^+}$, which also maximizes the increase of the objective function. In this case (Case below (B2)), we obtain a new feasible solution $u^+ = u(\theta^{j^+})$.

Now, if $\theta^{j^+} > 0$, then there is some index $k \in K$ such $u_k > 0$, $\gamma_k^{j^+} > 0$, and $\theta^{j^+} = u_k / \gamma_k^{j^+}$, so we can pick such an index k^- for the vector A^{k^-} leaving the basis K . We claim that

$K^+ = (K - \{k^-\}) \cup \{j^+\}$ is a basis. This is because the coefficient $\gamma_{k^-}^{j^+}$ associated with the column A^{k^-} is nonzero (in fact, $\gamma_{k^-}^{j^+} > 0$), so Equation (*), namely

$$A^{j^+} = \gamma_{k^-}^{j^+} A^{k^-} + \sum_{k \in K - \{k^-\}} \gamma_k^{j^+} A^k,$$

yields the equation

$$A^{k^-} = (\gamma_{k^-}^{j^+})^{-1} A^{j^+} - \sum_{k \in K - \{k^-\}} (\gamma_{k^-}^{j^+})^{-1} \gamma_k^{j^+} A^k,$$

and these equations imply that the subspaces spanned by the vectors $(A^k)_{k \in K}$ and the vectors $(A^k)_{k \in K^+}$ are identical. However, K is a basis of dimension m so this subspace has dimension m , and since K^+ also has m elements, it must be a basis. Therefore, $u^+ = u(\theta^{j^+})$ is a basic feasible solution.

The above case is the most common one, but other situations may arise. In what follows, we discuss all eventualities.

Case (A).

We have $c_j - \sum_{k \in K} \gamma_k^j c_k \leq 0$ for all $j \notin K$. Then it turns out that u is an *optimal solution*. Otherwise, we are in Case (B).

Case (B).

We have $c_j - \sum_{k \in K} \gamma_k^j c_k > 0$ for some $j \notin K$ (not necessarily unique). There are three subcases.

Case (B1).

If for some $j \notin K$ as above we also have $\gamma_k^j \leq 0$ for all $k \in K$, since $u_k \geq 0$ for all $k \in K$, this places no restriction on θ , and the objective function is *unbounded above*. This is demonstrated by Example 46.3 with $K = \{3, 4\}$ and $j = 2$ since $\gamma_{\{3,4\}}^2 = (-1, 0)$.

Case (B2).

There is some index $j^+ \notin K$ such that simultaneously

- (1) $c_{j^+} - \sum_{k \in K} \gamma_k^{j^+} c_k > 0$, which means that the objective function can potentially be increased;
- (2) There is some $k \in K$ such that $\gamma_k^{j^+} > 0$, and for every $k \in K$, if $\gamma_k^{j^+} > 0$ then $u_k > 0$, which implies that $\theta^{j^+} > 0$.

If we pick $\theta = \theta^{j^+}$ where

$$\theta^{j^+} = \min \left\{ \frac{u_k}{\gamma_k^{j^+}} \mid \gamma_k^{j^+} > 0, k \in K \right\} > 0,$$

then the feasible solution u^+ given by

$$u_i^+ = \begin{cases} u_i - \theta^{j^+} \gamma_i^{j^+} & \text{if } i \in K \\ \theta^{j^+} & \text{if } i = j^+ \\ 0 & \text{if } i \notin K \cup \{j^+\} \end{cases}$$

is a vertex of $\mathcal{P}(A, b)$. If we pick any index $k^- \in K$ such that $\theta^{j^+} = u_{k^-}/\gamma_{k^-}^{j^+}$, then $K^+ = (K - \{k^-\}) \cup \{j^+\}$ is a basis for u^+ . The vector A^{j^+} enters the new basis K^+ , and the vector A^{k^-} leaves the old basis K . This is a *pivoting step*. The objective function increases strictly. This is demonstrated by Example 46.2 with $K = \{3, 4, 5\}$, $j = 1$, and $k = 4$, Then $\gamma_{\{3,4,5\}}^1 = (-1, 1, 0)$, with $\gamma_4^1 = 1$. Since $u = (0, 0, 1, 3, 2)$, $\theta^1 = \frac{u_4}{\gamma_4^1} = 3$, and the new optimal solutions becomes $u^+ = (3, 0, 1 - 3(-1), 3 - 3(1), 2 - 3(0)) = (3, 0, 4, 0, 2)$.

Case (B3).

There is some index $j \notin K$ such that $c_j - \sum_{k \in K} \gamma_k^j c_k > 0$, and for each of the indices $j \notin K$ satisfying the above property we have simultaneously

- (1) $c_j - \sum_{k \in K} \gamma_k^j c_k > 0$, which means that the objective function can potentially be increased;
- (2) There is some $k \in K$ such that $\gamma_k^j > 0$, and $u_k = 0$, which implies that $\theta^j = 0$.

Consequently, the objective function *does not change*. In this case, u is a degenerate basic feasible solution.

We can associate to $u^+ = u$ a new basis K^+ as follows: Pick any index $j^+ \notin K$ such that

$$c_{j^+} - \sum_{k \in K} \gamma_k^{j^+} c_k > 0,$$

and any index $k^- \in K$ such that

$$\gamma_{k^-}^{j^+} > 0,$$

and let $K^+ = (K - \{k^-\}) \cup \{j^+\}$. As in Case (B2), The vector A^{j^+} enters the new basis K^+ , and the vector A^{k^-} leaves the old basis K . This is a *pivoting step*. However, the objective function *does not change* since $\theta^{j^+} = 0$. This is demonstrated by Example 46.1 with $K = \{3, 4\}$, $j = 2$, and $k = 3$.

It is easy to prove that in Case (A) the basic feasible solution u is an optimal solution, and that in Case (B1) the linear program is unbounded. We already proved that in Case (B2) the vector u^+ and its basis K^+ constitutes a basic feasible solution, and the proof in Case (B3) is similar. For details, see Ciarlet [41] (Chapter 10).

It is convenient to reinterpret the various cases considered by introducing the following sets:

$$\begin{aligned} B_1 &= \left\{ j \notin K \mid c_j - \sum_{k \in K} \gamma_k^j c_k > 0, \max_{k \in K} \gamma_k^j \leq 0 \right\} \\ B_2 &= \left\{ j \notin K \mid c_j - \sum_{k \in K} \gamma_k^j c_k > 0, \max_{k \in K} \gamma_k^j > 0, \min \left\{ \frac{u_k}{\gamma_k^j} \mid k \in K, \gamma_k^j > 0 \right\} > 0 \right\} \\ B_3 &= \left\{ j \notin K \mid c_j - \sum_{k \in K} \gamma_k^j c_k > 0, \max_{k \in K} \gamma_k^j > 0, \min \left\{ \frac{u_k}{\gamma_k^j} \mid k \in K, \gamma_k^j > 0 \right\} = 0 \right\}, \end{aligned}$$

and

$$B = B_1 \cup B_2 \cup B_3 = \left\{ j \notin K \mid c_j - \sum_{k \in K} \gamma_k^j c_k > 0 \right\}.$$

Then it is easy to see that the following equivalences hold:

$$\begin{aligned} \text{Case (A)} &\iff B = \emptyset, & \text{Case (B)} &\iff B \neq \emptyset \\ \text{Case (B1)} &\iff B_1 \neq \emptyset \\ \text{Case (B2)} &\iff B_2 \neq \emptyset \\ \text{Case (B3)} &\iff B_3 \neq \emptyset. \end{aligned}$$

Furthermore, Cases (A) and (B), Cases (B1) and (B3), and Cases (B2) and (B3) are mutually exclusive, while Cases (B1) and (B2) are not.

If Case (B1) and Case (B2) arise simultaneously, we opt for Case (B1) which says that the Linear Program (P) is unbounded and terminate the algorithm.

Here are a few remarks about the method.

In Case (B2), which is the path followed by the algorithm most frequently, various choices have to be made for the index $j^+ \notin K$ for which $\theta^{j^+} > 0$ (the new index in K^+). Similarly, various choices have to be made for the index $k^- \in K$ leaving K , but such choices are typically less important.

Similarly in Case (B3), various choices have to be made for the new index $j^+ \notin K$ going into K^+ . In Cases (B2) and (B3), criteria for making such choices are called *pivot rules*.

Case (B3) only arises when u is a degenerate vertex. But even if u is degenerate, Case (B2) may arise if $u_k > 0$ whenever $\gamma_k^j > 0$. It may also happen that u is nondegenerate but as a result of Case (B2), the new vertex u^+ is degenerate because at least two components $u_{k_1} - \theta^{j^+} \gamma_{k_1}^{j^+}$ and $u_{k_2} - \theta^{j^+} \gamma_{k_2}^{j^+}$ vanish for some distinct $k_1, k_2 \in K$.

Cases (A) and (B1) correspond to situations where the algorithm terminates, and Case (B2) can only arise a finite number of times during execution of the simplex algorithm, since the objective function is strictly increased from vertex to vertex and there are only finitely many vertices. Therefore, if the simplex algorithm is started on any initial basic feasible solution u_0 , then one of three mutually exclusive situations may arise:

- (1) There is a finite sequence of occurrences of Case (B2) and/or Case (B3) ending with an occurrence of Case (A). Then the last vertex produced by the algorithm is an optimal solution. This is what occurred in Examples 46.1 and 46.2.
- (2) There is a finite sequence of occurrences of Case (B2) and/or Case (B3) ending with an occurrence of Case (B1). We conclude that the problem is unbounded, and thus has no solution. This is what occurred in Example 46.3.
- (3) There is a finite sequence of occurrences of Case (B2) and/or Case (B3), followed by an infinite sequence of Case (B3). If this occurs, the algorithm visits the same basis twice. This a phenomenon known as *cycling*. In this eventually the algorithm fails to come to a conclusion.

There are examples for which cycling occur, although this is rare in practice. Such an example is given in Chvatal [40]; see Chapter 3, pages 31-32, for an example with seven variables and three equations that cycles after six iterations under a certain pivot rule.

The third possibility can be avoided by the choice of a suitable pivot rule. Two of these rules are *Bland's rule* and the *lexicographic rule*; see Chvatal [40] (Chapter 3, pages 34-38).

Bland's rule says: choose the smallest of the eligible incoming indices $j^+ \notin K$, and similarly choose the smallest of the eligible outgoing indices $k^- \in K$.

It can be proven that cycling cannot occur if Bland's rule is chosen as the pivot rule. The proof is very technical; see Chvatal [40] (Chapter 3, pages 37-38), Matousek and Gardner [123] (Chapter 5, Theorem 5.8.1), and Papadimitriou and Steiglitz [134] (Section 2.7). Therefore, assuming that some initial basic feasible solution is provided, and using a suitable pivot rule (such as Bland's rule), the simplex algorithm always terminates and either yields an optimal solution or reports that the linear program is unbounded. Unfortunately, Bland's rules is one of the slowest pivot rules.

The choice of a pivot rule affects greatly the number of pivoting steps that the simplex algorithms goes through. It is not our intention here to explain the various pivot rules. We simply mention the following rules, referring the reader to Matousek and Gardner [123] (Chapter 5, Section 5.7) or to the texts cited in Section 44.1.

1. Largest coefficient, or Dantzig's rule.
2. Largest increase.
3. Steepest edge.
4. Bland's Rule.
5. Random edge.

The steepest edge rule is one of the most popular. The idea is to maximize the ratio

$$\frac{c(u^+ - u)}{\|u^+ - u\|}.$$

The random edge rule picks the index $j^+ \notin K$ of the entering basis vector uniformly at random among all eligible indices.

Let us now return to the issue of the initialization of the simplex algorithm. We use the Linear Program (\widehat{P}) introduced during the proof of Theorem 45.7.

Consider a Linear Program $(P2)$

$$\begin{aligned} & \text{maximize} && cx \\ & \text{subject to} && Ax = b \text{ and } x \geq 0, \end{aligned}$$

in standard form where A is an $m \times n$ matrix of rank m .

First, observe that since the constraints are equations, we can ensure that $b \geq 0$, because every equation $a_i x = b_i$ where $b_i < 0$ can be replaced by $-a_i x = -b_i$. The next step is to introduce the Linear Program (\widehat{P}) in standard form

$$\begin{aligned} & \text{maximize} && -(x_{n+1} + \cdots + x_{n+m}) \\ & \text{subject to} && \widehat{A}\widehat{x} = b \text{ and } \widehat{x} \geq 0, \end{aligned}$$

where \widehat{A} and \widehat{x} are given by

$$\widehat{A} = (A \ I_m), \quad \widehat{x} = \begin{pmatrix} x_1 \\ \vdots \\ x_{n+m} \end{pmatrix}.$$

Since we assumed that $b \geq 0$, the vector $\widehat{x} = (0_n, b)$ is a feasible solution of (\widehat{P}) , in fact a basic feasible solution since the matrix associated with the indices $n+1, \dots, n+m$ is the identity matrix I_m . Furthermore, since $x_i \geq 0$ for all i , the objective function $-(x_{n+1} + \cdots + x_{n+m})$ is bounded above by 0.

If we execute the simplex algorithm with a pivot rule that prevents cycling, starting with the basic feasible solution $(0_n, d)$, since the objective function is bounded by 0, the simplex algorithm terminates with an optimal solution given by some basic feasible solution, say (u^*, w^*) , with $u^* \in \mathbb{R}^n$ and $w^* \in \mathbb{R}^m$.

As in the proof of Theorem 45.7, for every feasible solution $u \in \mathcal{P}(A, b)$, the vector $(u, 0_m)$ is an optimal solution of (\widehat{P}) . Therefore, if $w^* \neq 0$, then $\mathcal{P}(A, b) = \emptyset$, since otherwise for every feasible solution $u \in \mathcal{P}(A, b)$ the vector $(u, 0_m)$ would yield a value of the objective function $-(x_{n+1} + \cdots + x_{n+m})$ equal to 0, but (u^*, w^*) yields a strictly negative value since $w^* \neq 0$.

Otherwise, $w^* = 0$, and u^* is a feasible solution of $(P2)$. Since $(u^*, 0_m)$ is a basic feasible solution of (\widehat{P}) the columns corresponding to nonzero components of u^* are linearly independent. Some of the coordinates of u^* could be equal to 0, but since A has rank m we can add columns of A to obtain a basis K^* associated with u^* , and u^* is indeed a basic feasible solution of $(P2)$.

Running the simplex algorithm on the Linear Program \widehat{P} to obtain an initial feasible solution (u_0, K_0) of the linear program $(P2)$ is called *Phase I* of the simplex algorithm. Running the simplex algorithm on the Linear Program $(P2)$ with some initial feasible solution (u_0, K_0) is called *Phase II* of the simplex algorithm. If a feasible solution of the Linear Program $(P2)$ is readily available then Phase I is skipped. Sometimes, at the end of Phase I, an optimal solution of $(P2)$ is already obtained.

In summary, we proved the following fact worth recording.

Proposition 46.1. *For any Linear Program $(P2)$*

$$\begin{aligned} & \text{maximize} && cx \\ & \text{subject to} && Ax = b \text{ and } x \geq 0, \end{aligned}$$

in standard form, where A is an $m \times n$ matrix of rank m and $b \geq 0$, consider the Linear Program (\widehat{P}) in standard form

$$\begin{aligned} & \text{maximize} && -(x_{n+1} + \cdots + x_{n+m}) \\ & \text{subject to} && \widehat{A}\widehat{x} = b \text{ and } \widehat{x} \geq 0. \end{aligned}$$

The simplex algorithm with a pivot rule that prevents cycling started on the basic feasible solution $\widehat{x} = (0_n, b)$ of (\widehat{P}) terminates with an optimal solution (u^, w^*) .*

- (1) *If $w^* \neq 0$, then $\mathcal{P}(A, b) = \emptyset$, that is, the Linear Program $(P2)$ has no feasible solution.*
- (2) *If $w^* = 0$, then $\mathcal{P}(A, b) \neq \emptyset$, and u^* is a basic feasible solution of $(P2)$ associated with some basis K .*

Proposition 46.1 shows that determining whether the polyhedron $\mathcal{P}(A, b)$ defined by a system of equations $Ax = b$ and inequalities $x \geq 0$ is nonempty is decidable. This decision procedure uses a fail-safe version of the simplex algorithm (that prevents cycling), and the proof that it always terminates and returns an answer is nontrivial.

46.3 How to Perform a Pivoting Step Efficiently

We now discuss briefly how to perform the computation of (u^+, K^+) from a basic feasible solution (u, K) .

In order to avoid applying permutation matrices it is preferable to allow a basis K to be a sequence of indices, possibly out of order. Thus, for any $m \times n$ matrix A (with $m \leq n$)

and any sequence $K = (k_1, k_2, \dots, k_m)$ of m elements with $k_i \in \{1, \dots, n\}$, the matrix A_K denotes the $m \times m$ matrix whose i th column is the k_i th column of A , and similarly for any vector $u \in \mathbb{R}^n$ (resp. any linear form $c \in (\mathbb{R}^n)^*$), the vector $u_K \in \mathbb{R}^m$ (the linear form $c_K \in (\mathbb{R}^m)^*$) is the vector whose i th entry is the k_i th entry in u (resp. the linear whose i th entry is the k_i th entry in c).

For each nonbasic $j \notin K$, we have

$$A^j = \gamma_{k_1}^j A^{k_1} + \dots + \gamma_{k_m}^j A^{k_m} = A_K \gamma_K^j,$$

so the vector γ_K^j is given by $\gamma_K^j = A_K^{-1} A^j$, that is, by solving the system

$$A_K \gamma_K^j = A^j. \quad (*_\gamma)$$

To be very precise, since the vector γ_K^j depends on K its components should be denoted by $(\gamma_K^j)_{k_i}$, but as we said before, to simplify notation we write $\gamma_{k_i}^j$ instead of $(\gamma_K^j)_{k_i}$.

In order to decide which case applies ((A), (B1), (B2), (B3)), we need to compute the numbers $c_j - \sum_{k \in K} \gamma_k^j c_k$ for all $j \notin K$. For this, observe that

$$c_j - \sum_{k \in K} \gamma_k^j c_k = c_j - c_K \gamma_K^j = c_j - c_K A_K^{-1} A^j.$$

If we write $\beta_K = c_K A_K^{-1}$, then

$$c_j - \sum_{k \in K} \gamma_k^j c_k = c_j - \beta_K A^j,$$

and we see that $\beta_K^\top \in \mathbb{R}^m$ is the solution of the system $\beta_K^\top = (A_K^{-1})^\top c_K^\top$, which means that β_K^\top is the solution of the system

$$A_K^\top \beta_K^\top = c_K^\top. \quad (*_\beta)$$

Remark: Observe that since u is a basis feasible solution of (P) , we have $u_j = 0$ for all $j \notin K$, so u is the solution of the equation $A_K u_K = b$. As a consequence, the value of the objective function for u is $cu = c_K u_K = c_K A_K^{-1} b$. This fact will play a crucial role in Section 47.2 to show that when the simplex algorithm terminates with an optimal solution of the Linear Program (P) , then it also produces an optimal solution of the Dual Linear Program (D) .

Assume that we have a basic feasible solution u , a basis K for u , and that we also have the matrix A_K as well its inverse A_K^{-1} (perhaps implicitly) and also the inverse $(A_K^\top)^{-1}$ of A_K^\top (perhaps implicitly). Here is a description of an iteration step of the simplex algorithm, following almost exactly Chvatal (Chvatal [40], Chapter 7, Box 7.1).

An Iteration Step of the (Revised) Simplex Method

Step 1. Compute the numbers $c_j - \sum_{k \in K} \gamma_k^j c_k = c_j - \beta_K A^j$ for all $j \notin K$, and for this, compute β_K^\top as the solution of the system

$$A_K^\top \beta_K^\top = c_K^\top.$$

If $c_j - \beta_K A^j \leq 0$ for all $j \notin K$, stop and return the optimal solution u (Case (A)).

Step 2. If Case (B) arises, use a pivot rule to determine which index $j^+ \notin K$ should enter the new basis K^+ (the condition $c_{j^+} - \beta_K A^{j^+} > 0$ should hold).

Step 3. Compute $\max_{k \in K} \gamma_k^{j^+}$. For this, solve the linear system

$$A_K \gamma_K^{j^+} = A^{j^+}.$$

Step 4. If $\max_{k \in K} \gamma_k^{j^+} \leq 0$, then stop and report that Linear Program (P) is unbounded (Case (B1)).

Step 5. If $\max_{k \in K} \gamma_k^{j^+} > 0$, use the ratios $u_k / \gamma_k^{j^+}$ for all $k \in K$ such that $\gamma_k^{j^+} > 0$ to compute θ^{j^+} , and use a pivot rule to determine which index $k^- \in K$ such that $\theta^{j^+} = u_{k^-} / \gamma_{k^-}^{j^+}$ should leave K (Case (B2)).

If $\max_{k \in K} \gamma_k^{j^+} = 0$, then use a pivot rule to determine which index k^- for which $\gamma_{k^-}^{j^+} > 0$ should leave the basis K (Case (B3)).

Step 6. Update u , K , and A_K , to u^+ and K^+ , and A_{K^+} . During this step, given the basis K specified by the sequence $K = (k_1, \dots, k_\ell, \dots, k_m)$, with $k^- = k_\ell$, then K^+ is the sequence obtained by replacing k_ℓ by the incoming index j^+ , so $K^+ = (k_1, \dots, j^+, \dots, k_m)$ with j^+ in the ℓ th slot.

The vector u is easily updated. To compute A_{K^+} from A_K we take advantage of the fact that A_K and A_{K^+} only differ by a *single column*, namely the ℓ th column A^{j^+} , which is given by the linear combination

$$A^{j^+} = A_K \gamma_K^{j^+}.$$

To simplify notation, denote $\gamma_K^{j^+}$ by γ , and recall that $k^- = k_\ell$. If $K = (k_1, \dots, k_m)$, then $A_K = [A^{k_1} \cdots A^{k^-} \cdots A^{k_m}]$, and since A_{K^+} is the result of replacing the ℓ th column A^{k^-} of A_K by the column A^{j^+} , we have

$$A_{K^+} = [A^{k_1} \cdots A^{j^+} \cdots A^{k_m}] = [A^{k_1} \cdots A_K \gamma \cdots A^{k_m}] = A_K E(\gamma),$$

where $E(\gamma)$ is the following invertible matrix obtained from the identity matrix I_m by replacing its ℓ th column by γ :

$$E(\gamma) = \begin{pmatrix} 1 & & \gamma_1 & & \\ & \ddots & \vdots & & \\ & & 1 & \gamma_{\ell-1} & \\ & & & \gamma_\ell & \\ & & & \gamma_{\ell+1} & 1 \\ & & & \vdots & \ddots \\ & & & \gamma_m & & 1 \end{pmatrix}.$$

Since $\gamma_\ell = \gamma_{k^-}^{j^+} > 0$, the matrix $E(\gamma)$ is invertible, and it is easy to check that its inverse is given by

$$E(\gamma)^{-1} = \begin{pmatrix} 1 & -\gamma_\ell^{-1}\gamma_1 & & \\ & \ddots & \vdots & \\ & & 1 & -\gamma_\ell^{-1}\gamma_{\ell-1} \\ & & & \gamma_\ell^{-1} \\ & & & -\gamma_\ell^{-1}\gamma_{\ell+1} & 1 \\ & & & \vdots & \ddots \\ & & & -\gamma_\ell^{-1}\gamma_m & & 1 \end{pmatrix},$$

which is very cheap to compute. We also have

$$A_{K^+}^{-1} = E(\gamma)^{-1} A_K^{-1}.$$

Consequently, if A_K and A_K^{-1} are available, then A_{K^+} and $A_{K^+}^{-1}$ can be computed cheaply in terms of A_K and A_K^{-1} and matrices of the form $E(\gamma)$. Then the systems $(*_\gamma)$ to find the vectors γ_K^j can be solved cheaply.

Since

$$A_{K^+}^\top = E(\gamma)^\top A_K^\top$$

and

$$(A_{K^+}^\top)^{-1} = (A_K^\top)^{-1} (E(\gamma)^\top)^{-1},$$

the matrices $A_{K^+}^\top$ and $(A_{K^+}^\top)^{-1}$ can also be computed cheaply from A_K^\top , $(A_K^\top)^{-1}$, and matrices of the form $E(\gamma)^\top$. Thus the systems $(*_\beta)$ to find the linear forms β_K can also be solved cheaply.

A matrix of the form $E(\gamma)$ is called an *eta matrix*; see Chvatal [40] (Chapter 7). We showed that the matrix A_{K^s} obtained after s steps of the simplex algorithm can be written as

$$A_{K^s} = A_{K^{s-1}} E_s$$

for some eta matrix E_s , so A_{K^s} can be written as the product

$$A_{K^s} = E_1 E_2 \cdots E_s$$

of s eta matrices. Such a factorization is called an *eta factorization*. The eta factorization can be used to either invert A_{K^s} or to solve a system of the form $A_{K^s} \gamma = A^{j^+}$ iteratively. Which method is more efficient depends on the sparsity of the E_i .

In summary, there are cheap methods for finding the next basic feasible solution (u^+, K^+) from (u, K) . We simply wanted to give the reader a flavor of these techniques. We refer the reader to texts on linear programming for detailed presentations of methods for implementing efficiently the simplex method. In particular, the *revised simplex method* is presented in Chvatal [40], Papadimitriou and Steiglitz [134], Bertsimas and Tsitsiklis [21], and Vanderbei [181].

46.4 The Simplex Algorithm Using Tableaux

We now describe a formalism for presenting the simplex algorithm, namely (*full*) *tableaux*. This is the traditional formalism used in all books, modulo minor variations. A particularly nice feature of the tableau formalism is that the update of a tableau can be performed using elementary row operations *identical* to the operations used during the reduction of a matrix to row reduced echelon form (rref). What differs is the criterion for the choice of the pivot.

Since the quantities $c_j - c_K \gamma_K^j$ play a crucial role in determining which column A^j should come into the basis, the notation \bar{c}_j is used to denote $c_j - c_K \gamma_K^j$, which is called the *reduced cost* of the variable x_j . The reduced costs actually depend on K so to be very precise we should denote them by $(\bar{c}_K)_j$, but to simplify notation we write \bar{c}_j instead of $(\bar{c}_K)_j$. We will see shortly how $(\bar{c}_{K+})_i$ is computed in terms of $(\bar{c}_K)_i$.

Observe that the data needed to execute the next step of the simplex algorithm are

- (1) The current basic solution u_K and its basis $K = (k_1, \dots, k_m)$.
- (2) The reduced costs $\bar{c}_j = c_j - c_K A_K^{-1} A^j = c_j - c_K \gamma_K^j$, for all $j \notin K$.
- (3) The vectors $\gamma_K^j = (\gamma_{k_i}^j)_{i=1}^m$ for all $j \notin K$, that allow us to express each A^j as $A_K \gamma_K^j$.

All this information can be packed into a $(m + 1) \times (n + 1)$ matrix called a (*full*) *tableau* organized as follows:

$c_K u_K$	\bar{c}_1	\dots	\bar{c}_j	\dots	\bar{c}_n
u_{k_1}	γ_1^1	\dots	γ_1^j	\dots	γ_1^n
\vdots	\vdots		\vdots		\vdots
u_{k_m}	γ_m^1	\dots	γ_m^j	\dots	γ_m^n

It is convenient to think as the first row as Row 0, and of the first column as Column 0. Row 0 contains the current value of the objective function and the reduced costs. Column 0, except for its top entry, contains the components of the current basic solution u_K , and the remaining columns, except for their top entry, contain the vectors γ_K^j . Observe that the γ_K^j corresponding to indices j in K constitute a permutation of the identity matrix I_m . The entry $\gamma_{k_-}^{j+}$ is called the *pivot* element. A tableau together with the new basis $K^+ = (K - \{k^-\}) \cup \{j^+\}$ contains all the data needed to compute the new u_{K^+} , the new $\gamma_{K^+}^j$, and the new reduced costs $(\bar{c}_{K^+})_j$.

If we define the $m \times n$ matrix Γ as the matrix $\Gamma = [\gamma_K^1 \ \dots \ \gamma_K^n]$ whose j th column is γ_K^j , and \bar{c} as the row vector $\bar{c} = (\bar{c}_1 \ \dots \ \bar{c}_n)$, then the above tableau is denoted concisely by

$c_K u_K$	\bar{c}
u_K	Γ

We now show that the update of a tableau can be performed using elementary row operations identical to the operations used during the reduction of a matrix to row reduced echelon form (rref).

If $K = (k_1, \dots, k_m)$, j^+ is the index of the incoming basis vector, $k^- = k_\ell$ is the index of the column leaving the basis, and if $K^+ = (k_1, \dots, k_{\ell-1}, j^+, k_{\ell+1}, \dots, k_m)$, since $A_{K^+} = A_K E(\gamma_K^{j^+})$, the new columns $\gamma_{K^+}^j$ are computed in terms of the old columns γ_K^j using $(*_\gamma)$ and the equations

$$\gamma_{K^+}^j = A_{K^+}^{-1} A^j = E(\gamma_K^{j^+})^{-1} A_K^{-1} A^j = E(\gamma_K^{j^+})^{-1} \gamma_K^j.$$

Consequently, the matrix Γ^+ is given in terms of Γ by

$$\Gamma^+ = E(\gamma_K^{j^+})^{-1} \Gamma.$$

But the matrix $E(\gamma_K^{j^+})^{-1}$ is of the form

$$E(\gamma_K^{j^+})^{-1} = \begin{pmatrix} 1 & -(\gamma_{k^-}^{j^+})^{-1} \gamma_{k_1}^{j^+} & & \\ \ddots & \vdots & & \\ & 1 & -(\gamma_{k^-}^{j^+})^{-1} \gamma_{k_{\ell-1}}^{j^+} & \\ & & (\gamma_{k^-}^{j^+})^{-1} & \\ & & -(\gamma_{k^-}^{j^+})^{-1} \gamma_{k_{\ell+1}}^{j^+} & 1 \\ & & \vdots & \ddots \\ & & -(\gamma_{k^-}^{j^+})^{-1} \gamma_{k_m}^{j^+} & 1 \end{pmatrix},$$

with the column involving the γ s in the ℓ th column, and Γ^+ is obtained by applying the following elementary row operations to Γ :

1. Multiply Row ℓ by $1/\gamma_{k^-}^{j^+}$ (the inverse of the pivot) to make the entry on Row ℓ and Column j^+ equal to 1.
2. Subtract $\gamma_{k_i}^{j^+} \times$ (the normalized) Row ℓ from Row i , for $i = 1, \dots, \ell-1, \ell+1, \dots, m$.

These are *exactly* the elementary row operations that reduce the ℓ th column $\gamma_K^{j^+}$ of Γ to the ℓ th column of the identity matrix I_m . Thus, this step is identical to the sequence of steps that the procedure to convert a matrix to row reduced echelon form executes on the ℓ th column of the matrix. The only difference is the criterion for the choice of the pivot.

Since the new basic solution u_{K^+} is given by $u_{K^+} = A_{K^+}^{-1} b$, we have

$$u_{K^+} = E(\gamma_K^{j^+})^{-1} A_K^{-1} b = E(\gamma_K^{j^+})^{-1} u_K.$$

This means that u_+ is obtained from u_K by applying exactly the *same* elementary row operations that were applied to Γ . Consequently, just as in the procedure for reducing a

matrix to rref, we can apply elementary row operations to the matrix $[u_k \ \Gamma]$, which consists of rows $1, \dots, m$ of the tableau.

Once the new matrix Γ^+ is obtained, the new reduced costs are given by the following proposition.

Proposition 46.2. *Given any Linear Program (P2) in standard form*

$$\begin{aligned} & \text{maximize} && cx \\ & \text{subject to} && Ax = b \text{ and } x \geq 0, \end{aligned}$$

where A is an $m \times n$ matrix of rank m , if (u, K) is a basic (not necessarily feasible) solution of (P2) and if $K^+ = (K - \{k^-\}) \cup \{j^+\}$, with $K = (k_1, \dots, k_m)$ and $k^- = k_\ell$, then for $i = 1, \dots, n$ we have

$$c_i - c_{K^+} \gamma_{K^+}^i = c_i - c_K \gamma_K^i - \frac{\gamma_{k^-}^i}{\gamma_{k^-}^{j^+}} (c_{j^+} - c_K \gamma_K^{j^+}).$$

Using the reduced cost notation, the above equation is

$$(\bar{c}_{K^+})_i = (\bar{c}_K)_i - \frac{\gamma_{k^-}^i}{\gamma_{k^-}^{j^+}} (\bar{c}_K)_{j^+}.$$

Proof. Without any loss of generality and to simplify notation assume that $K = (1, \dots, m)$ and write j for j^+ and ℓ for k_m . Since $\gamma_K^i = A_K^{-1} A^i$, $\gamma_{K^+}^i = A_{K^+}^{-1} A^i$, and $A_{K^+} = A_K E(\gamma_K^j)$, we have

$$c_i - c_{K^+} \gamma_{K^+}^i = c_i - c_{K^+} A_{K^+}^{-1} A^i = c_i - c_{K^+} E(\gamma_K^j)^{-1} A_K^{-1} A^i = c_i - c_{K^+} E(\gamma_K^j)^{-1} \gamma_K^i,$$

where

$$E(\gamma_K^j)^{-1} = \begin{pmatrix} 1 & -(\gamma_\ell^j)^{-1} \gamma_1^j \\ \ddots & \vdots \\ 1 & -(\gamma_\ell^j)^{-1} \gamma_{\ell-1}^j \\ & (\gamma_\ell^j)^{-1} \\ & -(\gamma_\ell^j)^{-1} \gamma_{\ell+1}^j & 1 \\ & \vdots & \ddots \\ & -(\gamma_\ell^j)^{-1} \gamma_m^j & 1 \end{pmatrix}$$

where the ℓ th column contains the γ s. Since $c_{K^+} = (c_1, \dots, c_{\ell-1}, c_j, c_{\ell+1}, \dots, c_m)$, we have

$$c_{K^+} E(\gamma_K^j)^{-1} = \left(c_1, \dots, c_{\ell-1}, \frac{c_j}{\gamma_\ell^j} - \sum_{k=1, k \neq \ell}^m c_k \frac{\gamma_k^j}{\gamma_\ell^j}, c_{\ell+1}, \dots, c_m \right),$$

and

$$\begin{aligned}
c_{K^+} E(\gamma_K^j)^{-1} \gamma_K^i &= \left(c_1 \quad \dots \quad c_{\ell-1} \quad \frac{c_j}{\gamma_\ell^j} - \sum_{k=1, k \neq \ell}^m c_k \frac{\gamma_k^j}{\gamma_\ell^j} \quad c_{\ell+1} \quad \dots \quad c_m \right) \begin{pmatrix} \gamma_1^i \\ \vdots \\ \gamma_{\ell-1}^i \\ \gamma_\ell^i \\ \gamma_{\ell+1}^i \\ \vdots \\ \gamma_m^i \end{pmatrix} \\
&= \sum_{k=1, k \neq \ell}^m c_k \gamma_k^i + \frac{\gamma_\ell^i}{\gamma_\ell^j} \left(c_j - \sum_{k=1, k \neq \ell}^m c_k \gamma_k^j \right) \\
&= \sum_{k=1, k \neq \ell}^m c_k \gamma_k^i + \frac{\gamma_\ell^i}{\gamma_\ell^j} \left(c_j + c_\ell \gamma_\ell^j - \sum_{k=1}^m c_k \gamma_k^j \right) \\
&= \sum_{k=1}^m c_k \gamma_k^i + \frac{\gamma_\ell^i}{\gamma_\ell^j} \left(c_j - \sum_{k=1}^m c_k \gamma_k^j \right) \\
&= c_K \gamma_K^i + \frac{\gamma_\ell^i}{\gamma_\ell^j} (c_j - c_K \gamma_K^j),
\end{aligned}$$

and thus

$$c_i - c_{K^+} \gamma_{K^+}^i = c_i - c_{K^+} E(\gamma_K^j)^{-1} \gamma_K^i = c_i - c_K \gamma_K^i - \frac{\gamma_\ell^i}{\gamma_\ell^j} (c_j - c_K \gamma_K^j),$$

as claimed. \square

Since $(\gamma_{k^-}^1, \dots, \gamma_{k^-}^n)$ is the ℓ -th row of Γ , we see that Proposition 46.2 shows that

$$\bar{c}_{K^+} = \bar{c}_K - \frac{(\bar{c}_K)_{j^+}}{\gamma_{k^-}^{j^+}} \Gamma_\ell, \quad (\dagger)$$

where Γ_ℓ denotes the ℓ -th row of Γ and $\gamma_{k^-}^{j^+}$ is the pivot. This means that \bar{c}_{K^+} is obtained by the elementary row operations which consist of first normalizing the ℓ -th row by dividing it by the pivot $\gamma_{k^-}^{j^+}$, and then subtracting $(\bar{c}_K)_{j^+} \times$ the normalized Row ℓ from \bar{c}_K . These are exactly the row operations that make the reduced cost $(\bar{c}_K)_{j^+}$ zero.

Remark: It is easy to show that we also have

$$\bar{c}_{K^+} = c - c_{K^+} \Gamma^+.$$

We saw in Section 46.2 that the change in the objective function after a pivoting step during which column j^+ comes in and column k^- leaves is given by

$$\theta^{j^+} \left(c_{j^+} - \sum_{k \in K} \gamma_k^{j^+} c_k \right) = \theta^{j^+} (\bar{c}_K)_{j^+},$$

where

$$\theta^{j^+} = \frac{u_{k^-}}{\gamma_{k^-}^{j^+}}.$$

If we denote the value of the objective function $c_K u_K$ by z_K , then we see that

$$z_{K^+} = z_K + \frac{(\bar{c}_K)_{j^+}}{\gamma_{k^-}^{j^+}} u_{k^-}.$$

This means that the new value z_{K^+} of the objective function is obtained by first normalizing the ℓ th row by dividing it by the pivot $\gamma_{k^-}^{j^+}$, and then adding $(\bar{c}_K)_{j^+} \times$ the zeroth entry of the normalized ℓ th line by $(\bar{c}_K)_{j^+}$ to the zeroth entry of line 0.

In updating the reduced costs, we subtract rather than add $(\bar{c}_K)_{j^+} \times$ the normalized row ℓ from row 0. This suggests storing $-z_K$ as the zeroth entry on line 0 rather than z_K , because then all the entries row 0 are updated by the *same* elementary row operations. Therefore, from now on, we use tableau of the form

$-c_K u_K$	\bar{c}_1	\cdots	\bar{c}_j	\cdots	\bar{c}_n
u_{k_1}	γ_1^1	\cdots	γ_1^j	\cdots	γ_1^n
\vdots	\vdots		\vdots		\vdots
u_{k_m}	γ_m^1	\cdots	γ_m^j	\cdots	γ_m^n

The simplex algorithm first chooses the incoming column j^+ by picking some column for which $\bar{c}_j > 0$, and then chooses the outgoing column k^- by considering the ratios $u_k / \gamma_k^{j^+}$ for which $\gamma_k^{j^+} > 0$ (along column j^+), and picking k^- to achieve the minimum of these ratios.

Here is an illustration of the simplex algorithm using elementary row operations on an example from Papadimitriou and Steiglitz [134] (Section 2.9).

Example 46.4. Consider the linear program

$$\text{maximize } -2x_2 - x_4 - 5x_7$$

subject to

$$x_1 + x_2 + x_3 + x_4 = 4$$

$$x_1 + x_5 = 2$$

$$x_3 + x_6 = 3$$

$$3x_2 + x_3 + x_7 = 6$$

$$x_1, x_2, x_3, x_4, x_5, x_6, x_7 \geq 0.$$

We have the basic feasible solution $u = (0, 0, 0, 4, 2, 3, 6)$, with $K = (4, 5, 6, 7)$. Since $c_K = (-1, 0, 0, -5)$ and $c = (0, -2, 0, -1, 0, 0, -5)$ the first tableau is

34	1	14	6	0	0	0	0
$u_4 = 4$	1	1	1	1	0	0	0
$u_5 = 2$	(1)	0	0	0	1	0	0
$u_6 = 3$	0	0	1	0	0	1	0
$u_7 = 6$	0	3	1	0	0	0	1

Since $\bar{c}_j = c_j - c_K \gamma_K^j$, Row 0 is obtained by subtracting $-1 \times$ Row 1 and $-5 \times$ Row 4 from $c = (0, -2, 0, -1, 0, 0, -5)$. Let us pick Column $j^+ = 1$ as the incoming column. We have the ratios (for positive entries on Column 1)

$$4/1, 2/1,$$

and since the minimum is 2, we pick the outgoing column to be Column $k^- = 5$. The pivot 1 is indicated in red. The new basis is $K = (4, 1, 6, 7)$. Next we apply row operations to reduce Column 1 to the second vector of the identity matrix I_4 . For this, we subtract Row 2 from Row 1. We get the tableau

34	1	14	6	0	0	0	0
$u_4 = 2$	0	1	1	1	-1	0	0
$u_1 = 2$	(1)	0	0	0	1	0	0
$u_6 = 3$	0	0	1	0	0	1	0
$u_7 = 6$	0	3	1	0	0	0	1

To compute the new reduced costs, we want to set \bar{c}_1 to 0, so we apply the identical row operations and subtract Row 2 from Row 0 to obtain the tableau

32	0	14	6	0	-1	0	0
$u_4 = 2$	0	1	(1)	1	-1	0	0
$u_1 = 2$	1	0	0	0	1	0	0
$u_6 = 3$	0	0	1	0	0	1	0
$u_7 = 6$	0	3	1	0	0	0	1

Next, pick Column $j^+ = 3$ as the incoming column. We have the ratios (for positive entries on Column 3)

$$2/1, 3/1, 6/1,$$

and since the minimum is 2, we pick the outgoing column to be Column $k^- = 4$. The pivot 1 is indicated in red and the new basis is $K = (3, 1, 6, 7)$. Next we apply row operations to reduce Column 3 to the first vector of the identity matrix I_4 . For this, we subtract Row 1 from Row 3 and from Row 4 and obtain the tableau:

32	0	14	6	0	-1	0	0
$u_3 = 2$	0	1	(1)	1	-1	0	0
$u_1 = 2$	1	0	0	0	1	0	0
$u_6 = 1$	0	-1	0	-1	1	1	0
$u_7 = 4$	0	2	0	-1	1	0	1

To compute the new reduced costs, we want to set \bar{c}_3 to 0, so we subtract $6 \times$ Row 1 from Row 0 to get the tableau

20	0	8	0	-6	5	0	0
$u_3 = 2$	0	(1)	1	1	-1	0	0
$u_1 = 2$	1	0	0	0	1	0	0
$u_6 = 1$	0	-1	0	-1	1	1	0
$u_7 = 4$	0	2	0	-1	1	0	1

Next we pick $j^+ = 2$ as the incoming column. We have the ratios (for positive entries on Column 2)

$$2/1, 4/2,$$

and since the minimum is 2, we pick the outgoing column to be Column $k^- = 3$. The pivot 1 is indicated in red and the new basis is $K = (2, 1, 6, 7)$. Next we apply row operations to reduce Column 2 to the first vector of the identity matrix I_4 . For this, we add Row 1 to Row 3 and subtract $2 \times$ Row 1 from Row 4 to obtain the tableau:

20	0	8	0	-6	5	0	0
$u_2 = 2$	0	(1)	1	1	-1	0	0
$u_1 = 2$	1	0	0	0	1	0	0
$u_6 = 3$	0	0	1	0	0	1	0
$u_7 = 0$	0	0	-2	-3	3	0	1

To compute the new reduced costs, we want to set \bar{c}_2 to 0, so we subtract $8 \times$ Row 1 from Row 0 to get the tableau

4	0	0	-8	-14	13	0	0
$u_2 = 2$	0	1	1	1	-1	0	0
$u_1 = 2$	1	0	0	0	1	0	0
$u_6 = 3$	0	0	1	0	0	1	0
$u_7 = 0$	0	0	-2	-3	(3)	0	1

The only possible incoming column corresponds to $j^+ = 5$. We have the ratios (for positive entries on Column 5)

$$2/1, 0/3,$$

and since the minimum is 0, we pick the outgoing column to be Column $k^- = 7$. The pivot 3 is indicated in red and the new basis is $K = (2, 1, 6, 5)$. Since the minimum is 0, the basis $K = (2, 1, 6, 5)$ is degenerate (indeed, the component corresponding to the index 5 is 0). Next we apply row operations to reduce Column 5 to the fourth vector of the identity matrix I_4 . For this, we multiply Row 4 by $1/3$, and then add the normalized Row 4 to Row 1 and subtract the normalized Row 4 from Row 2 to obtain the tableau:

4	0	0	-8	-14	13	0	0
$u_2 = 2$	0	1	$1/3$	0	0	0	$1/3$
$u_1 = 2$	1	0	$2/3$	1	0	0	$-1/3$
$u_6 = 3$	0	0	1	0	0	1	0
$u_5 = 0$	0	0	$-2/3$	-1	1	0	$1/3$

To compute the new reduced costs, we want to set \bar{c}_5 to 0, so we subtract $13 \times$ Row 4 from Row 0 to get the tableau

4	0	0	$2/3$	-1	0	0	$-13/3$
$u_2 = 2$	0	1	$1/3$	0	0	0	$1/3$
$u_1 = 2$	1	0	2/3	1	0	0	$-1/3$
$u_6 = 3$	0	0	1	0	0	1	0
$u_5 = 0$	0	0	$-2/3$	-1	1	0	$1/3$

The only possible incoming column corresponds to $j^+ = 3$. We have the ratios (for positive entries on Column 3)

$$2/(1/3) = 6, 2/(2/3) = 3, 3/1 = 3,$$

and since the minimum is 3, we pick the outgoing column to be Column $k^- = 1$. The pivot $2/3$ is indicated in red and the new basis is $K = (2, 3, 6, 5)$. Next we apply row operations to reduce Column 3 to the second vector of the identity matrix I_4 . For this, we multiply Row 2 by $3/2$, subtract $(1/3) \times$ (normalized Row 2) from Row 1, and subtract normalized Row 2 from Row 3, and add $(2/3) \times$ (normalized Row 2) to Row 4 to obtain the tableau:

4	0	0	$2/3$	-1	0	0	$-13/3$
$u_2 = 1$	$-1/2$	1	0	$-1/2$	0	0	$1/2$
$u_3 = 3$	$3/2$	0	1	$3/2$	0	0	$-1/2$
$u_6 = 0$	$-3/2$	0	0	$-3/2$	0	1	$1/2$
$u_5 = 2$	1	0	0	0	1	0	0

To compute the new reduced costs, we want to set \bar{c}_3 to 0, so we subtract $(2/3) \times$ Row 2 from Row 0 to get the tableau

2	-1	0	0	-2	0	0	-4
$u_2 = 1$	$-1/2$	1	0	$-1/2$	0	0	$1/2$
$u_3 = 3$	$3/2$	0	1	$3/2$	0	0	$-1/2$
$u_6 = 0$	$-3/2$	0	0	$-3/2$	0	1	$1/2$
$u_5 = 2$	1	0	0	0	1	0	0

Since all the reduced cost are ≤ 0 , we have reached an optimal solution, namely $(0, 1, 3, 0, 2, 0, 0, 0)$, with optimal value -2 .

The progression of the simplex algorithm from one basic feasible solution to another corresponds to the visit of vertices of the polyhedron \mathcal{P} associated with the constraints of the linear program illustrated in Figure 46.4.

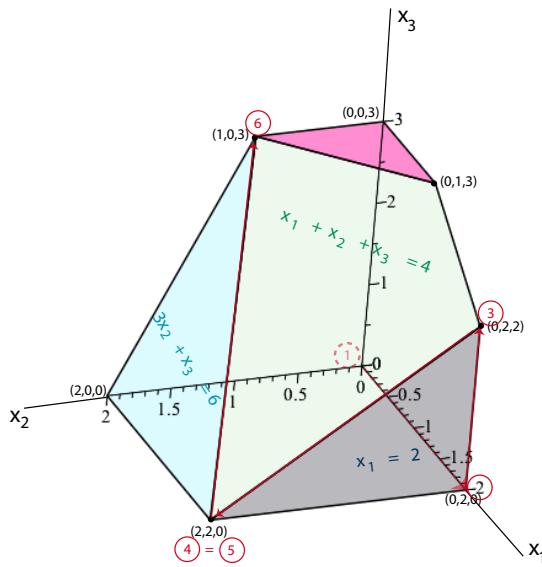

Figure 46.4: The polytope \mathcal{P} associated with the linear program optimized by the tableau method. The red arrowed path traces the progression of the simplex method from the origin to the vertex $(0, 1, 3)$.

As a final comment, if it is necessary to run Phase I of the simplex algorithm, in the event that the simplex algorithm terminates with an optimal solution $(u^*, 0_m)$ and a basis K^* such that some $u_i = 0$, then the basis K^* contains indices of basic columns A^j corresponding to slack variables that need to be *driven out* of the basis. This is easy to achieve by performing a pivoting step involving some other column j^+ corresponding to one of the original variables (not a slack variable) for which $(\gamma_{K^*})_i^{j^+} \neq 0$. In such a step, it doesn't matter whether $(\gamma_{K^*})_i^{j^+} < 0$ or $(\bar{c}_{K^*})_{j^+} \leq 0$. If the original matrix A has no redundant equations, such a step

is always possible. Otherwise, $(\gamma_{K^*})_i^j = 0$ for all non-slack variables, so we detected that the i th equation is redundant and we can delete it.

Other presentations of the tableau method can be found in Bertsimas and Tsitsiklis [21] and Papadimitriou and Steiglitz [134].

46.5 Computational Efficiency of the Simplex Method

Let us conclude with a few comments about the efficiency of the simplex algorithm. In *practice*, it was observed by Dantzig that for linear programs with $m < 50$ and $m + n < 200$, the simplex algorithms typically requires less than $3m/2$ iterations, but at most $3m$ iterations. This fact agrees with more recent empirical experiments with much larger programs that show that the number iterations is bounded by $3m$. Thus, it was somewhat of a shock in 1972 when Klee and Minty found a linear program with n variables and n equations for which the simplex algorithm with Dantzig's pivot rule requires requires $2^n - 1$ iterations. This program (taken from Chvatal [40], page 47) is reproduced below:

$$\begin{aligned} \text{maximize} \quad & \sum_{j=1}^n 10^{n-j} x_j \\ \text{subject to} \quad & \left(2 \sum_{j=1}^{i-1} 10^{i-j} x_j \right) + x_i \leq 100^{i-1} \\ & x_j \geq 0, \end{aligned}$$

for $i = 1, \dots, n$ and $j = 1, \dots, n$.

If $p = \max(m, n)$, then, in terms of worse case behavior, for all currently known pivot rules, the simplex algorithm has exponential complexity in p . However, as we said earlier, in practice, nasty examples such as the Klee–Minty example seem to be rare, and the number of iterations appears to be linear in m .

Whether or not a pivot rule (a clairvoyant rule) for which the simplex algorithms runs in polynomial time in terms of m is still an *open problem*.

The *Hirsch conjecture* claims that there is some pivot rule such that the simplex algorithm finds an optimal solution in $O(p)$ steps. The best bound known so far due to Kalai and Kleitman is $m^{1+\ln n} = (2n)^{\ln m}$. For more on this topic, see Matousek and Gardner [123] (Section 5.9) and Bertsimas and Tsitsiklis [21] (Section 3.7).

Researchers have investigated the problem of finding upper bounds on the expected number of pivoting steps if a randomized pivot rule is used. Bounds better than 2^m (but of course, not polynomial) have been found.

Understanding the complexity of linear programming, in particular of the simplex algorithm, is still ongoing. The interested reader is referred to Matousek and Gardner [123] (Chapter 5, Section 5.9) for some pointers.

In the next section we consider important theoretical criteria for determining whether a set of constraints $Ax \leq b$ and $x \geq 0$ has a solution or not.

46.6 Summary

The main concepts and results of this chapter are listed below:

- Degenerate and nondegenerate basic feasible solution.
- Pivoting step.
- Pivot rule.
- Cycling.
- Bland's rule, Dantzig's rule, steepest edge rule, random edge rule, largest increase rule, lexicographic rule.
- Phase I and Phase II of the simplex algorithm.
- eta matrix, eta factorization.
- Revised simplex method.
- Reduced cost.
- Full tableaux.
- The Hirsch conjecture.

46.7 Problems

Problem 46.1. In Section 46.2 prove that if Case (A) arises, then the basic feasible solution u is an optimal solution. Prove that if Case (B1) arises, then the linear program is unbounded. Prove that if Case (B3) arises, then (u^+, K^+) is a basic feasible solution.

Problem 46.2. In Section 46.2 prove that the following equivalences hold:

$$\begin{aligned} \text{Case (A)} &\iff B = \emptyset, & \text{Case (B)} &\iff B \neq \emptyset \\ \text{Case (B1)} &\iff B_1 \neq \emptyset \\ \text{Case (B2)} &\iff B_2 \neq \emptyset \\ \text{Case (B3)} &\iff B_3 \neq \emptyset. \end{aligned}$$

Furthermore, prove that Cases (A) and (B), Cases (B1) and (B3), and Cases (B2) and (B3) are mutually exclusive, while Cases (B1) and (B2) are not.

Problem 46.3. Consider the linear program (due to E.M.L. Beale):

$$\begin{aligned} \text{maximize } & (3/4)x_1 - 150x_2 + (1/50)x_3 - 6x_4 \\ \text{subject to } & (1/4)x_1 - 60x_2 - (1/25)x_3 + 9x_4 \leq 0 \\ & (1/4)x_1 - 90x_2 - (1/50)x_3 + 3x_4 \leq 0 \\ & x_3 \leq 1 \\ & x_1 \geq 0, x_2 \geq 0, x_3 \geq 0, x_4 \geq 0. \end{aligned}$$

(1) Convert the above program to standard form.

(2) Show that if we apply the simplex algorithm with the pivot rule which selects the column entering the basis as the column of smallest index, then the method cycles.

Problem 46.4. Read carefully the proof given by Chvatal that the lexicographic pivot rule and Bland's pivot rule prevent cycling; see Chvatal [40] (Chapter 3, pages 34-38).

Problem 46.5. Solve the following linear program (from Chvatal [40], Chapter 3, page 44) using the two-phase simplex algorithm:

$$\begin{aligned} \text{maximize } & 3x_1 + x_2 \\ \text{subject to } & x_1 - x_2 \leq -1 \\ & -x_1 - x_2 \leq -3 \\ & 2x_1 + x_2 \leq 4 \\ & x_1 \geq 0, x_2 \geq 0. \end{aligned}$$

Problem 46.6. Solve the following linear program (from Chvatal [40], Chapter 3, page 44) using the two-phase simplex algorithm:

$$\begin{aligned} \text{maximize } & 3x_1 + x_2 \\ \text{subject to } & x_1 - x_2 \leq -1 \\ & -x_1 - x_2 \leq -3 \\ & 2x_1 + x_2 \leq 2 \\ & x_1 \geq 0, x_2 \geq 0. \end{aligned}$$

Problem 46.7. Solve the following linear program (from Chvatal [40], Chapter 3, page 44) using the two-phase simplex algorithm:

$$\begin{aligned} & \text{maximize} && 3x_1 + x_2 \\ & \text{subject to} && \\ & && x_1 - x_2 \leq -1 \\ & && -x_1 - x_2 \leq -3 \\ & && 2x_1 - x_2 \leq 2 \\ & && x_1 \geq 0, x_2 \geq 0. \end{aligned}$$

Problem 46.8. Show that the following linear program (from Chvatal [40], Chapter 3, page 43) is unbounded.

$$\begin{aligned} & \text{maximize} && x_1 + 3x_2 - x_3 \\ & \text{subject to} && \\ & && 2x_1 + 2x_2 - x_3 \leq 10 \\ & && 3x_1 - 2x_2 + x_3 \leq 10 \\ & && x_1 - 3x_2 + x_3 \leq 10 \\ & && x_1 \geq 0, x_2 \geq 0, x_3 \geq 0. \end{aligned}$$

Hint. Try $x_1 = 0, x_3 = t$, and a suitable value for x_2 .

Chapter 47

Linear Programming and Duality

47.1 Variants of the Farkas Lemma

If A is an $m \times n$ matrix and if $b \in \mathbb{R}^m$ is a vector, it is known from linear algebra that the linear system $Ax = b$ has no solution iff there is some linear form $y \in (\mathbb{R}^m)^*$ such that $yA = 0$ and $yb \neq 0$. This means that the linear form y vanishes on the columns A^1, \dots, A^n of A but does not vanish on b . Since the linear form y defines the linear hyperplane H of equation $yz = 0$ (with $z \in \mathbb{R}^m$), **geometrically the equation $Ax = b$ has no solution iff there is a linear hyperplane H containing A^1, \dots, A^n and not containing b .** This is a kind of separation theorem that says that **the vectors A^1, \dots, A^n and b can be separated by some linear hyperplane H .**

What we would like to do is to generalize this kind of criterion, first to a system $Ax = b$ subject to the constraints $x \geq 0$, and next to sets of inequality constraints $Ax \leq b$ and $x \geq 0$. There are indeed such criteria going under the name of *Farkas lemma*.

The key is a separation result involving polyhedral cones known as the Farkas–Minkowski proposition. We have the following fundamental separation lemma.

Proposition 47.1. *Let $C \subseteq \mathbb{R}^n$ be a closed nonempty (convex) cone. For any point $a \in \mathbb{R}^n$, if $a \notin C$, then there is a linear hyperplane H (through 0) such that*

1. *C lies in one of the two half-spaces determined by H .*
2. *$a \notin H$*
3. *a lies in the other half-space determined by H .*

We say that H strictly separates C and a .

Proposition 47.1, which is illustrated in Figure 47.1, is an easy consequence of another separation theorem that asserts that given any two nonempty closed convex sets A and B of \mathbb{R}^n with A compact, there is a hyperplane H strictly separating A and B (which means that $A \cap H = \emptyset$, $B \cap H = \emptyset$, that A lies in one of the two half-spaces determined by H ,

and B lies in the other half-space determined by H); see Gallier [72] (Chapter 7, Corollary 7.4 and Proposition 7.3). This proof is nontrivial and involves a geometric version of the Hahn–Banach theorem.

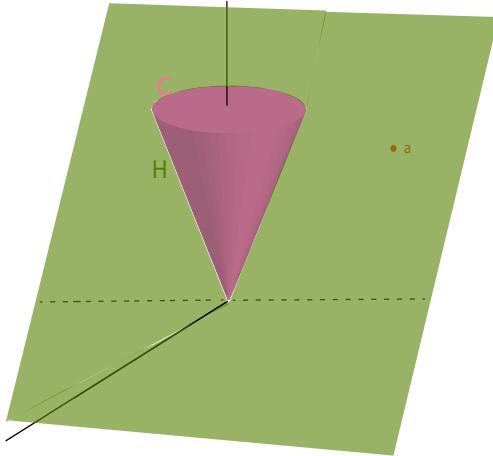

Figure 47.1: In \mathbb{R}^3 , the olive green hyperplane H separates the cone C from the orange point a .

The Farkas–Minkowski proposition is Proposition 47.1 applied to a polyhedral cone

$$C = \{\lambda_1 a_1 + \cdots + \lambda_n a_n \mid \lambda_i \geq 0, i = 1, \dots, n\}$$

where $\{a_1, \dots, a_n\}$ is a *finite* number of vectors $a_i \in \mathbb{R}^n$. By Proposition 44.2, any polyhedral cone is closed, so Proposition 47.1 applies and we obtain the following separation lemma.

Proposition 47.2. (Farkas–Minkowski) *Let $C \subseteq \mathbb{R}^n$ be a nonempty polyhedral cone $C = \text{cone}(\{a_1, \dots, a_n\})$. For any point $b \in \mathbb{R}^n$, if $b \notin C$, then there is a linear hyperplane H (through 0) such that*

1. *C lies in one of the two half-spaces determined by H .*
2. *$b \notin H$*
3. *b lies in the other half-space determined by H .*

Equivalently, there is a nonzero linear form $y \in (\mathbb{R}^n)^$ such that*

1. *$ya_i \geq 0$ for $i = 1, \dots, n$.*
2. *$yb < 0$.*

A direct proof of the Farkas–Minkowski proposition not involving Proposition 47.1 is given at the end of this section.

Remark: There is a generalization of the Farkas–Minkowski proposition applying to infinite dimensional real Hilbert spaces; see Theorem 48.12 (or Ciarlet [41], Chapter 9).

Proposition 47.2 implies our first version of Farkas' lemma.

Proposition 47.3. (*Farkas Lemma, Version I*) *Let A be an $m \times n$ matrix and let $b \in \mathbb{R}^m$ be any vector. The linear system $Ax = b$ has no solution $x \geq 0$ iff there is some nonzero linear form $y \in (\mathbb{R}^m)^*$ such that $yA \geq 0_n^\top$ and $yb < 0$.*

Proof. First assume that there is some nonzero linear form $y \in (\mathbb{R}^m)^*$ such that $yA \geq 0$ and $yb < 0$. If $x \geq 0$ is a solution of $Ax = b$, then we get

$$yAx = yb,$$

but if $yA \geq 0$ and $x \geq 0$, then $yAx \geq 0$, and yet by hypothesis $yb < 0$, a contradiction.

Next assume that $Ax = b$ has no solution $x \geq 0$. This means that b does not belong to the polyhedral cone $C = \text{cone}(\{A^1, \dots, A^n\})$ spanned by the columns of A . By Proposition 47.2, there is a nonzero linear form $y \in (\mathbb{R}^m)^*$ such that

$$1. \quad yA^j \geq 0 \text{ for } j = 1, \dots, n.$$

$$2. \quad yb < 0,$$

which says that $yA \geq 0_n^\top$ and $yb < 0$. □

Next consider the solvability of a system of inequalities of the form $Ax \leq b$ and $x \geq 0$.

Proposition 47.4. (*Farkas Lemma, Version II*) *Let A be an $m \times n$ matrix and let $b \in \mathbb{R}^m$ be any vector. The system of inequalities $Ax \leq b$ has no solution $x \geq 0$ iff there is some nonzero linear form $y \in (\mathbb{R}^m)^*$ such that $y \geq 0_m^\top$, $yA \geq 0_n^\top$ and $yb < 0$.*

Proof. We use the trick of linear programming which consists of adding “slack variables” z_i to convert inequalities $a_i x \leq b_i$ into equations $a_i x + z_i = b_i$ with $z_i \geq 0$ already discussed just before Definition 44.9. If we let $z = (z_1, \dots, z_m)$, it is obvious that the system $Ax \leq b$ has a solution $x \geq 0$ iff the equation

$$(A \quad I_m) \begin{pmatrix} x \\ z \end{pmatrix} = b$$

has a solution $\begin{pmatrix} x \\ z \end{pmatrix}$ with $x \geq 0$ and $z \geq 0$. Now by Farkas I, the above system has no solution with $x \geq 0$ and $z \geq 0$ iff there is some nonzero linear form $y \in (\mathbb{R}^m)^*$ such that

$$y(A \quad I_m) \geq 0_{n+m}^\top$$

and $yb < 0$, that is, $yA \geq 0_n^\top$, $y \geq 0_m^\top$ and $yb < 0$. □

In the next section we use Farkas II to prove the duality theorem in linear programming. Observe that by taking the negation of the equivalence in Farkas II we obtain a criterion of solvability, namely:

The system of inequalities $Ax \leq b$ has a solution $x \geq 0$ iff for every nonzero linear form $y \in (\mathbb{R}^m)^$ such that $y \geq 0_m^\top$, if $yA \geq 0_n^\top$, then $yb \geq 0$.*

We now prove the Farkas–Minkowski proposition without using Proposition 47.1. This approach uses a basic property of the distance function from a point to a closed set.

Definition 47.1. Let $X \subseteq \mathbb{R}^n$ be any nonempty set and let $a \in \mathbb{R}^n$ be any point. The *distance* $d(a, X)$ from a to X is defined as

$$d(a, X) = \inf_{x \in X} \|a - x\|.$$

Here, $\|\cdot\|$ denotes the Euclidean norm.

Proposition 47.5. *Let $X \subseteq \mathbb{R}^n$ be any nonempty set and let $a \in \mathbb{R}^n$ be any point. If X is closed, then there is some $z \in X$ such that $\|a - z\| = d(a, X)$.*

Proof. Since X is nonempty, pick any $x_0 \in X$, and let $r = \|a - x_0\|$. If $B_r(a)$ is the closed ball $B_r(a) = \{x \in \mathbb{R}^n \mid \|x - a\| \leq r\}$, then clearly

$$d(a, X) = \inf_{x \in X} \|a - x\| = \inf_{x \in X \cap B_r(a)} \|a - x\|.$$

Since $B_r(a)$ is compact and X is closed, $K = X \cap B_r(a)$ is also compact. But the function $x \mapsto \|a - x\|$ defined on the compact set K is continuous, and the image of a compact set by a continuous function is compact, so by Heine–Borel it has a minimum that is achieved by some $z \in K \subseteq X$. \square

Remark: If U is a nonempty, closed and convex subset of a Hilbert space V , a standard result of Hilbert space theory (the projection lemma, see Proposition 48.5) asserts that for any $v \in V$ there is a *unique* $p \in U$ such that

$$\|v - p\| = \inf_{u \in U} \|v - u\| = d(v, U),$$

and

$$\langle p - v, u - p \rangle \geq 0 \quad \text{for all } u \in U.$$

Here $\|w\| = \sqrt{\langle w, w \rangle}$, where $\langle -, - \rangle$ is the inner product of the Hilbert space V .

We can now give a proof of the Farkas–Minkowski proposition (Proposition 47.2) that does not use Proposition 47.1. This proof is adapted from Matousek and Gardner [123] (Chapter 6, Sections 6.5).

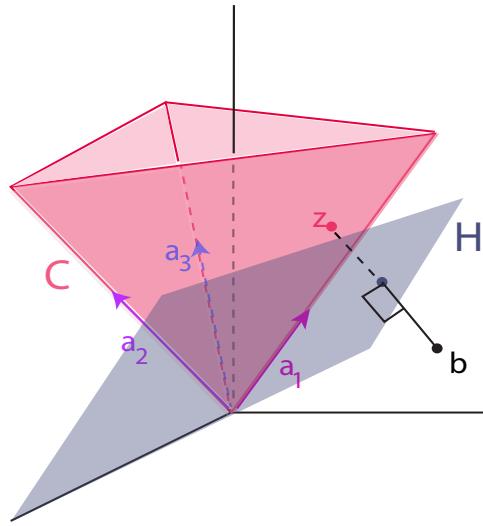

Figure 47.2: The hyperplane H , perpendicular to $z - b$, separates the point b from $C = \text{cone}(\{a_1, a_2, a_3\})$.

Proof of the Farkas–Minkowski proposition. Let $C = \text{cone}(\{a_1, \dots, a_m\})$ be a polyhedral cone (nonempty) and assume that $b \notin C$. By Proposition 44.2, the polyhedral cone is closed, and by Proposition 47.5 there is some $z \in C$ such that $d(b, C) = \|b - z\|$; that is, z is a point of C closest to b . Since $b \notin C$ and $z \in C$ we have $u = z - b \neq 0$, and we claim that the linear hyperplane H orthogonal to u does the job, as illustrated in Figure 47.2.

First let us show that

$$\langle u, z \rangle = \langle z - b, z \rangle = 0. \quad (*_1)$$

This is trivial if $z = 0$, so assume $z \neq 0$. If $\langle u, z \rangle \neq 0$, then either $\langle u, z \rangle > 0$ or $\langle u, z \rangle < 0$. In either case we show that we can find some point $z' \in C$ closer to b than z is, a contradiction.

Case 1: $\langle u, z \rangle > 0$.

Let $z' = (1 - \alpha)z$ for any α such that $0 < \alpha < 1$. Then $z' \in C$ and since $u = z - b$,

$$z' - b = (1 - \alpha)z - (z - u) = u - \alpha z,$$

so

$$\|z' - b\|^2 = \|u - \alpha z\|^2 = \|u\|^2 - 2\alpha \langle u, z \rangle + \alpha^2 \|z\|^2.$$

If we pick $\alpha > 0$ such that $\alpha < 2\langle u, z \rangle / \|z\|^2$, then $-2\alpha \langle u, z \rangle + \alpha^2 \|z\|^2 < 0$, so $\|z' - b\|^2 < \|u\|^2 = \|z - b\|^2$, contradicting the fact that z is a point of C closest to b .

Case 2: $\langle u, z \rangle < 0$.

Let $z' = (1 + \alpha)z$ for any $\alpha \geq -1$. Then $z' \in C$ and since $u = z - b$, we have $z' - b = (1 + \alpha)z - (z - u) = u + \alpha z$ so

$$\|z' - b\|^2 = \|u + \alpha z\|^2 = \|u\|^2 + 2\alpha \langle u, z \rangle + \alpha^2 \|z\|^2,$$

and if

$$0 < \alpha < -2\langle u, z \rangle / \|z\|^2,$$

then $2\alpha\langle u, z \rangle + \alpha^2 \|z\|^2 < 0$, so $\|z' - b\|^2 < \|u\|^2 = \|z - b\|^2$, a contradiction as above.

Therefore $\langle u, z \rangle = 0$. We have

$$\langle u, u \rangle = \langle u, z - b \rangle = \langle u, z \rangle - \langle u, b \rangle = -\langle u, b \rangle,$$

and since $u \neq 0$, we have $\langle u, u \rangle > 0$, so $\langle u, u \rangle = -\langle u, b \rangle$ implies that

$$\langle u, b \rangle < 0. \quad (*_2)$$

It remains to prove that $\langle u, a_i \rangle \geq 0$ for $i = 1, \dots, m$. Pick any $x \in C$ such that $x \neq z$. We claim that

$$\langle b - z, x - z \rangle \leq 0. \quad (*_3)$$

Otherwise $\langle b - z, x - z \rangle > 0$, that is, $\langle z - b, x - z \rangle < 0$, and we show that we can find some point $z' \in C$ on the line segment $[z, x]$ closer to b than z is.

For any α such that $0 \leq \alpha \leq 1$, we have $z' = (1 - \alpha)z + \alpha x = z + \alpha(x - z) \in C$, and since $z' - b = z - b + \alpha(x - z)$ we have

$$\|z' - b\|^2 = \|z - b + \alpha(x - z)\|^2 = \|z - b\|^2 + 2\alpha\langle z - b, x - z \rangle + \alpha^2 \|x - z\|^2,$$

so for any $\alpha > 0$ such that

$$\alpha < -2\langle z - b, x - z \rangle / \|x - z\|^2,$$

we have $2\alpha\langle z - b, x - z \rangle + \alpha^2 \|x - z\|^2 < 0$, which implies that $\|z' - b\|^2 < \|z - b\|^2$, contradicting that z is a point of C closest to b .

Since $\langle b - z, x - z \rangle \leq 0$, $u = z - b$, and by $(*_1)$, $\langle u, z \rangle = 0$, we have

$$0 \geq \langle b - z, x - z \rangle = \langle -u, x - z \rangle = -\langle u, x \rangle + \langle u, z \rangle = -\langle u, x \rangle,$$

which means that

$$\langle u, x \rangle \geq 0 \quad \text{for all } x \in C, \quad (*_3)$$

as claimed. In particular,

$$\langle u, a_i \rangle \geq 0 \quad \text{for } i = 1, \dots, m. \quad (*_4)$$

Then by $(*_2)$ and $(*_4)$, the linear form defined by $y = u^\top$ satisfies the properties $yb < 0$ and $ya_i \geq 0$ for $i = 1, \dots, m$, which proves the Farkas–Minkowski proposition. \square

There are other ways of proving the Farkas–Minkowski proposition, for instance using minimally infeasible systems or Fourier–Motzkin elimination; see Matousek and Gardner [123] (Chapter 6, Sections 6.6 and 6.7).

47.2 The Duality Theorem in Linear Programming

Let (P) be the linear program

$$\begin{aligned} & \text{maximize} && cx \\ & \text{subject to} && Ax \leq b \text{ and } x \geq 0, \end{aligned}$$

with A a $m \times n$ matrix, and assume that (P) has a feasible solution and is bounded above. Since by hypothesis the objective function $x \mapsto cx$ is bounded on $\mathcal{P}(A, b)$, it might be useful to deduce an *upper bound* for cx from the inequalities $Ax \leq b$, for any $x \in \mathcal{P}(A, b)$. We can do this as follows: for every inequality

$$a_i x \leq b_i \quad 1 \leq i \leq m,$$

pick a nonnegative scalar y_i , multiply both sides of the above inequality by y_i obtaining

$$y_i a_i x \leq y_i b_i \quad 1 \leq i \leq m,$$

(the direction of the inequality is preserved since $y_i \geq 0$), and then add up these m equations, which yields

$$(y_1 a_1 + \cdots + y_m a_m) x \leq y_1 b_1 + \cdots + y_m b_m.$$

If we can pick the $y_i \geq 0$ such that

$$c \leq y_1 a_1 + \cdots + y_m a_m,$$

then since $x_j \geq 0$, we have

$$cx \leq (y_1 a_1 + \cdots + y_m a_m) x \leq y_1 b_1 + \cdots + y_m b_m,$$

namely we found an upper bound of the value cx of the objective function of (P) for any feasible solution $x \in \mathcal{P}(A, b)$. If we let y be the linear form $y = (y_1, \dots, y_m)$, then since

$$A = \begin{pmatrix} a_1 \\ \vdots \\ a_m \end{pmatrix}$$

$y_1 a_1 + \cdots + y_m a_m = yA$, and $y_1 b_1 + \cdots + y_m b_m = yb$, what we did was to look for some $y \in (\mathbb{R}^m)^*$ such that

$$c \leq yA, \quad y \geq 0,$$

so that we have

$$cx \leq yb \quad \text{for all } x \in \mathcal{P}(A, b). \tag{*}$$

Then it is natural to look for a “best” value of yb , namely a minimum value, which leads to the definition of the *dual* of the linear program (P) , a notion due to John von Neumann.

Definition 47.2. Given any Linear Program (P)

$$\begin{aligned} & \text{maximize } cx \\ & \text{subject to } Ax \leq b \text{ and } x \geq 0, \end{aligned}$$

with A an $m \times n$ matrix, the *dual* (D) of (P) is the following optimization problem:

$$\begin{aligned} & \text{minimize } yb \\ & \text{subject to } yA \geq c \text{ and } y \geq 0, \end{aligned}$$

where $y \in (\mathbb{R}^m)^*$.

The variables y_1, \dots, y_m are called the *dual variables*. The original Linear Program (P) is called the *primal* linear program and the original variables x_1, \dots, x_n are the *primal variables*.

Here is an explicit example of a linear program and its dual.

Example 47.1. Consider the linear program illustrated by Figure 47.3

$$\begin{aligned} & \text{maximize } 2x_1 + 3x_2 \\ & \text{subject to} \\ & \quad 4x_1 + 8x_2 \leq 12 \\ & \quad 2x_1 + x_2 \leq 3 \\ & \quad 3x_1 + 2x_2 \leq 4 \\ & \quad x_1 \geq 0, x_2 \geq 0. \end{aligned}$$

Its dual linear program is illustrated in Figure 47.4

$$\begin{aligned} & \text{minimize } 12y_1 + 3y_2 + 4y_3 \\ & \text{subject to} \\ & \quad 4y_1 + 2y_2 + 3y_3 \geq 2 \\ & \quad 8y_1 + y_2 + 2y_3 \geq 3 \\ & \quad y_1 \geq 0, y_2 \geq 0, y_3 \geq 0. \end{aligned}$$

It can be checked that $(x_1, x_2) = (1/2, 5/4)$ is an optimal solution of the primal linear program, with the maximum value of the objective function $2x_1 + 3x_2$ equal to $19/4$, and that $(y_1, y_2, y_3) = (5/16, 0, 1/4)$ is an optimal solution of the dual linear program, with the minimum value of the objective function $12y_1 + 3y_2 + 4y_3$ also equal to $19/4$.

Observe that in the Primal Linear Program (P), we are looking for a *vector* $x \in \mathbb{R}^n$ maximizing the form cx , and that the constraints are determined by the action of the *rows* of the matrix A on x . On the other hand, in the Dual Linear Program (D), we are looking for a *linear form* $y \in (\mathbb{R}^*)^m$ minimizing the form yb , and the constraints are determined by

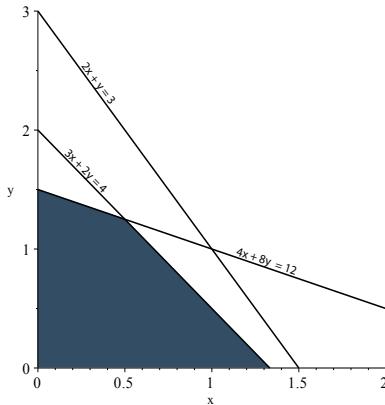

Figure 47.3: The \mathcal{H} -polytope for the linear program of Example 47.1. Note $x_1 \rightarrow x$ and $x_2 \rightarrow y$.

the action of y on the *columns* of A . This is the sense in which (D) is the *dual* ((P)). In most presentations, the fact that (P) and (D) perform a search for a solution in spaces that are dual to each other is obscured by excessive use of transposition.

To convert the Dual Program (D) to a standard maximization problem we change the objective function yb to $-b^\top y^\top$ and the inequality $yA \geq c$ to $-A^\top y^\top \leq -c^\top$. The Dual Linear Program (D') is now stated as (D')

$$\begin{aligned} & \text{maximize} && -b^\top y^\top \\ & \text{subject to} && -A^\top y^\top \leq -c^\top \text{ and } y^\top \geq 0, \end{aligned}$$

where $y \in (\mathbb{R}^m)^*$. Observe that the dual in maximization form (D'') of the Dual Program (D') gives back the Primal Program (P) .

The above discussion established the following inequality known as *weak duality*.

Proposition 47.6. *(Weak Duality) Given any Linear Program (P)*

$$\begin{aligned} & \text{maximize} && cx \\ & \text{subject to} && Ax \leq b \text{ and } x \geq 0, \end{aligned}$$

with A an $m \times n$ matrix, for any feasible solution $x \in \mathbb{R}^n$ of the Primal Problem (P) and every feasible solution $y \in (\mathbb{R}^m)^*$ of the Dual Problem (D) , we have

$$cx \leq yb.$$

Definition 47.3. We say that the Dual Linear Program (D) is *bounded below* if $\{yb \mid y^\top \in \mathcal{P}(-A^\top, -c^\top)\}$ is bounded below.

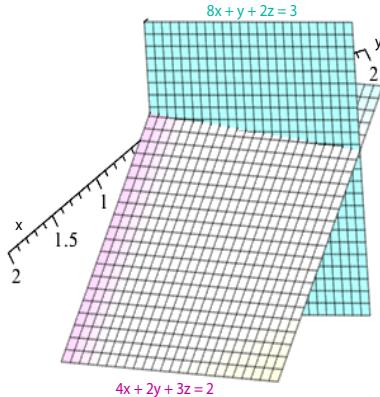

Figure 47.4: The \mathcal{H} -polyhedron for the dual linear program of Example 47.1 is the spacial region “above” the pink plane and in “front” of the blue plane. Note $y_1 \rightarrow x$, $y_2 \rightarrow y$, and $y_3 \rightarrow z$.

What happens if x^* is an optimal solution of (P) and if y^* is an optimal solution of (D) ? We have $c x^* \leq y^* b$, but is there a “duality gap,” that is, is it possible that $c x^* < y^* b$?

The answer is **no**, this is the *strong duality theorem*. Actually, the strong duality theorem asserts more than this.

Theorem 47.7. (*Strong Duality for Linear Programming*) Let (P) be any linear program

$$\begin{aligned} & \text{maximize} && cx \\ & \text{subject to} && Ax \leq b \text{ and } x \geq 0, \end{aligned}$$

with A an $m \times n$ matrix. The Primal Problem (P) has a feasible solution and is bounded above iff the Dual Problem (D) has a feasible solution and is bounded below. Furthermore, if (P) has a feasible solution and is bounded above, then for every optimal solution x^* of (P) and every optimal solution y^* of (D) , we have

$$c x^* = y^* b.$$

Proof. If (P) has a feasible solution and is bounded above, then we know from Proposition 45.1 that (P) has some optimal solution. Let x^* be any optimal solution of (P) . First we will show that (D) has a feasible solution v .

Let $\mu = c x^*$ be the maximum of the objective function $x \mapsto cx$. Then for any $\epsilon > 0$, the system of inequalities

$$Ax \leq b, \quad x \geq 0, \quad cx \geq \mu + \epsilon$$

has no solution, since otherwise μ would not be the maximum value of the objective function cx . We would like to apply Farkas II, so first we transform the above system of inequalities

into the system

$$\begin{pmatrix} A \\ -c \end{pmatrix} x \leq \begin{pmatrix} b \\ -(\mu + \epsilon) \end{pmatrix}.$$

By Proposition 47.4 (Farkas II), there is some linear form $(\lambda, z) \in (\mathbb{R}^{m+1})^*$ such that $\lambda \geq 0$, $z \geq 0$,

$$(\lambda \ z) \begin{pmatrix} A \\ -c \end{pmatrix} \geq 0_m^\top,$$

and

$$(\lambda \ z) \begin{pmatrix} b \\ -(\mu + \epsilon) \end{pmatrix} < 0,$$

which means that

$$\lambda A - zc \geq 0_m^\top, \quad \lambda b - z(\mu + \epsilon) < 0,$$

that is,

$$\begin{aligned} \lambda A &\geq zc \\ \lambda b &< z(\mu + \epsilon) \\ \lambda &\geq 0, \quad z \geq 0. \end{aligned}$$

On the other hand, since $x^* \geq 0$ is an optimal solution of the system $Ax \leq b$, by Farkas II again (by taking the negation of the equivalence), since $\lambda A \geq 0$ (for the same λ as before), we must have

$$\lambda b \geq 0. \tag{*_1}$$

We claim that $z > 0$. Otherwise, since $z \geq 0$, we must have $z = 0$, but then

$$\lambda b < z(\mu + \epsilon)$$

implies

$$\lambda b < 0, \tag{*_2}$$

and since $\lambda b \geq 0$ by $(*_1)$, we have a contradiction. Consequently, we can divide by $z > 0$ without changing the direction of inequalities, and we obtain

$$\begin{aligned} \frac{\lambda}{z} A &\geq c \\ \frac{\lambda}{z} b &< \mu + \epsilon \\ \frac{\lambda}{z} &\geq 0, \end{aligned}$$

which shows that $v = \lambda/z$ is a feasible solution of the Dual Problem (D) . However, weak duality (Proposition 47.6) implies that $cx^* = \mu \leq yb$ for any feasible solution $y \geq 0$ of the Dual Program (D) , so (D) is bounded below and by Proposition 45.1 applied to the version of (D) written as a maximization problem, we conclude that (D) has some optimal solution.

For any optimal solution y^* of (D) , since v is a feasible solution of (D) such that $vb < \mu + \epsilon$, we must have

$$\mu \leq y^*b < \mu + \epsilon,$$

and since our reasoning is valid for *any* $\epsilon > 0$, we conclude that $cx^* = \mu = y^*b$.

If we assume that the dual program (D) has a feasible solution and is bounded below, since the dual of (D) is (P) , we conclude that (P) is also feasible and bounded above. \square

The strong duality theorem can also be proven by the simplex method, because when it terminates with an optimal solution of (P) , the final tableau also produces an optimal solution y of (D) that can be read off the reduced costs of columns $n+1, \dots, n+m$ by flipping their signs. We follow the proof in Ciarlet [41] (Chapter 10).

Theorem 47.8. *Consider the Linear Program (P) ,*

$$\begin{aligned} & \text{maximize } cx \\ & \text{subject to } Ax \leq b \text{ and } x \geq 0, \end{aligned}$$

its equivalent version $(P2)$ in standard form,

$$\begin{aligned} & \text{maximize } \hat{c}\hat{x} \\ & \text{subject to } \hat{A}\hat{x} = b \text{ and } \hat{x} \geq 0, \end{aligned}$$

where \hat{A} is an $m \times (n+m)$ matrix, \hat{c} is a linear form in $(\mathbb{R}^{n+m})^$, and $\hat{x} \in \mathbb{R}^{n+m}$, given by*

$$\hat{A} = (A \ I_m), \quad \hat{c} = (c \ 0_m^\top), \quad x = \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix}, \quad \bar{x} = \begin{pmatrix} x_{n+1} \\ \vdots \\ x_{n+m} \end{pmatrix}, \quad \hat{x} = \begin{pmatrix} x \\ \bar{x} \end{pmatrix},$$

and the Dual (D) of (P) given by

$$\begin{aligned} & \text{minimize } yb \\ & \text{subject to } yA \geq c \text{ and } y \geq 0, \end{aligned}$$

where $y \in (\mathbb{R}^m)^$. If the simplex algorithm applied to the Linear Program $(P2)$ terminates with an optimal solution (\hat{u}^*, K^*) , where \hat{u}^* is a basic feasible solution and K^* is a basis for \hat{u}^* , then $y^* = \hat{c}_{K^*} \hat{A}_{K^*}^{-1}$ is an optimal solution for (D) such that $\hat{c}\hat{u}^* = y^*b$. Furthermore, y^* is given in terms of the reduced costs by $y^* = -((\bar{c}_{K^*})_{n+1} \dots (\bar{c}_{K^*})_{n+m})$.*

Proof. We know that K^* is a subset of $\{1, \dots, n+m\}$ consisting of m indices such that the corresponding columns of \hat{A} are linearly independent. Let $N^* = \{1, \dots, n+m\} - K^*$. The simplex method terminates with an optimal solution in Case (A), namely when

$$\hat{c}_j - \sum_{k \in K} \gamma_k^j \hat{c}_k \leq 0 \quad \text{for all } j \in N^*,$$

where $\widehat{A}^j = \sum_{k \in K^*} \gamma_k^j \widehat{A}^k$, or using the notations of Section 46.3,

$$\widehat{c}_j - \widehat{c}_{K^*} \widehat{A}_{K^*}^{-1} \widehat{A}^j \leq 0 \quad \text{for all } j \in N^*.$$

The above inequalities can be written as

$$\widehat{c}_{N^*} - \widehat{c}_{K^*} \widehat{A}_{K^*}^{-1} \widehat{A}_{N^*} \leq 0_n^\top,$$

or equivalently as

$$\widehat{c}_{K^*} \widehat{A}_{K^*}^{-1} \widehat{A}_{N^*} \geq \widehat{c}_{N^*}. \quad (*_1)$$

The value of the objective function for the optimal solution \widehat{u}^* is $\widehat{c} \widehat{u}^* = \widehat{c}_{K^*} \widehat{u}_{K^*}^*$, and since $\widehat{u}_{K^*}^*$ satisfies the equation $\widehat{A}_{K^*} \widehat{u}_{K^*}^* = b$, the value of the objective function is

$$\widehat{c}_{K^*} \widehat{u}_{K^*}^* = \widehat{c}_{K^*} \widehat{A}_{K^*}^{-1} b. \quad (*_2)$$

Then if we let $y^* = \widehat{c}_{K^*} \widehat{A}_{K^*}^{-1}$, obviously we have $y^* b = \widehat{c}_{K^*} \widehat{u}_{K^*}^*$, so if we can prove that y^* is a feasible solution of the Dual Linear program (D) , by weak duality, y^* is an optimal solution of (D) . We have

$$y^* \widehat{A}_{K^*} = \widehat{c}_{K^*} \widehat{A}_{K^*}^{-1} \widehat{A}_{K^*} = \widehat{c}_{K^*}, \quad (*_3)$$

and by $(*_1)$ we get

$$y^* \widehat{A}_{N^*} = \widehat{c}_{K^*} \widehat{A}_{K^*}^{-1} \widehat{A}_{N^*} \geq \widehat{c}_{N^*}. \quad (*_4)$$

Let P be the $(n+m) \times (n+m)$ permutation matrix defined so that

$$\widehat{A} P = (A \ I_m) P = (\widehat{A}_{K^*} \ \widehat{A}_{N^*}).$$

Then we also have

$$\widehat{c} P = (c \ 0_m^\top) P = (\widehat{c}_{K^*} \ \widehat{c}_{N^*}).$$

Using Equations $(*_3)$ and $(*_4)$ we obtain

$$y^* (\widehat{A}_{K^*} \ \widehat{A}_{N^*}) \geq (\widehat{c}_{K^*} \ \widehat{c}_{N^*}),$$

that is,

$$y^* (A \ I_m) P \geq (c \ 0_m^\top) P,$$

which is equivalent to

$$y^* (A \ I_m) \geq (c \ 0_m^\top),$$

that is

$$y^* A \geq c, \quad y \geq 0,$$

and these are exactly the conditions that say that y^* is a feasible solution of the Dual Program (D) .

The reduced costs are given by $(\widehat{c}_{K^*})_i = \widehat{c}_i - \widehat{c}_{K^*} \widehat{A}_{K^*}^{-1} \widehat{A}^i$, for $i = 1, \dots, n+m$. But for $i = n+j$ with $j = 1, \dots, m$ each column \widehat{A}^{n+j} is the j th vector of the identity matrix I_m and by definition $\widehat{c}_{n+j} = 0$, so

$$(\widehat{c}_{K^*})_{n+j} = -(\widehat{c}_{K^*} \widehat{A}_{K^*}^{-1})_j = -y_j^* \quad j = 1, \dots, m,$$

as claimed. \square

The fact that the above proof is fairly short is deceptive because this proof relies on the fact that there are versions of the simplex algorithm using pivot rules that prevent cycling, but the proof that such pivot rules work correctly is quite lengthy. Other proofs are given in Matousek and Gardner [123] (Chapter 6, Sections 6.3), Chvatal [40] (Chapter 5), and Papadimitriou and Steiglitz [134] (Section 2.7).

Observe that since the last m rows of the final tableau are actually obtained by multiplying $[u \ \widehat{A}]$ by $\widehat{A}_{K^*}^{-1}$, the $m \times m$ matrix consisting of the last m columns and last m rows of the final tableau is $\widehat{A}_{K^*}^{-1}$ (basically, the simplex algorithm has performed the steps of a Gauss–Jordan reduction). This fact allows saving some steps in the primal dual method.

By combining weak duality and strong duality, we obtain the following theorem which shows that exactly four cases arise.

Theorem 47.9. (*Duality Theorem of Linear Programming*) Let (P) be any linear program

$$\begin{aligned} & \text{maximize} && cx \\ & \text{subject to} && Ax \leq b \text{ and } x \geq 0, \end{aligned}$$

and let (D) be its dual program

$$\begin{aligned} & \text{minimize} && yb \\ & \text{subject to} && yA \geq c \text{ and } y \geq 0, \end{aligned}$$

with A an $m \times n$ matrix. Then exactly one of the following possibilities occur:

- (1) Neither (P) nor (D) has a feasible solution.
- (2) (P) is unbounded and (D) has no feasible solution.
- (3) (P) has no feasible solution and (D) is unbounded.
- (4) Both (P) and (D) have a feasible solution. Then both have an optimal solution, and for every optimal solution x^* of (P) and every optimal solution y^* of (D) , we have

$$cx^* = y^*b.$$

An interesting corollary of Theorem 47.9 is that there is a test to determine whether a Linear Program (P) has an optimal solution.

Corollary 47.10. *The Primal Program (P) has an optimal solution iff the following set of constraints is satisfiable:*

$$\begin{aligned} Ax &\leq b \\ yA &\geq c \\ cx &\geq yb \\ x &\geq 0, \quad y \geq 0_m^\top. \end{aligned}$$

In fact, for any feasible solution (x^*, y^*) of the above system, x^* is an optimal solution of (P) and y^* is an optimal solution of (D) .

47.3 Complementary Slackness Conditions

Another useful corollary of the strong duality theorem is the following result known as the *equilibrium theorem*.

Theorem 47.11. (Equilibrium Theorem) *For any Linear Program (P) and its Dual Linear Program (D) (with set of inequalities $Ax \leq b$ where A is an $m \times n$ matrix, and objective function $x \mapsto cx$), for any feasible solution x of (P) and any feasible solution y of (D) , x and y are optimal solutions iff*

$$y_i = 0 \quad \text{for all } i \text{ for which } \sum_{j=1}^n a_{ij}x_j < b_i \quad (*_D)$$

and

$$x_j = 0 \quad \text{for all } j \text{ for which } \sum_{i=1}^m y_i a_{ij} > c_j. \quad (*_P)$$

Proof. First assume that $(*_D)$ and $(*_P)$ hold. The equations in $(*_D)$ say that $y_i = 0$ unless $\sum_{j=1}^n a_{ij}x_j = b_i$, hence

$$yb = \sum_{i=1}^m y_i b_i = \sum_{i=1}^m y_i \sum_{j=1}^n a_{ij}x_j = \sum_{i=1}^m \sum_{j=1}^n y_i a_{ij}x_j.$$

Similarly, the equations in $(*_P)$ say that $x_j = 0$ unless $\sum_{i=1}^m y_i a_{ij} = c_j$, hence

$$cx = \sum_{j=1}^n c_j x_j = \sum_{j=1}^n \sum_{i=1}^m y_i a_{ij}x_j.$$

Consequently, we obtain

$$cx = yb.$$

By weak duality (Proposition 47.6), we have

$$cx \leq yb = cx$$

for all feasible solutions x of (P) , so x is an optimal solution of (P) . Similarly,

$$yb = cx \leq yb$$

for all feasible solutions y of (D) , so y is an optimal solution of (D) .

Let us now assume that x is an optimal solution of (P) and that y is an optimal solution of (D) . Then as in the proof of Proposition 47.6,

$$\sum_{j=1}^n c_j x_j \leq \sum_{i=1}^m \sum_{j=1}^n y_i a_{ij} x_j \leq \sum_{i=1}^m y_i b_i.$$

By strong duality, since x and y are optimal solutions the above inequalities are actually equalities, so in particular we have

$$\sum_{j=1}^n \left(c_j - \sum_{i=1}^m y_i a_{ij} \right) x_j = 0.$$

Since x and y are feasible, $x_i \geq 0$ and $y_j \geq 0$, so if $\sum_{i=1}^m y_i a_{ij} > c_j$, we must have $x_j = 0$. Similarly, we have

$$\sum_{i=1}^m y_i \left(\sum_{j=1}^n a_{ij} x_j - b_i \right) = 0,$$

so if $\sum_{j=1}^n a_{ij} x_j < b_i$, then $y_i = 0$. □

The equations in $(*_D)$ and $(*_P)$ are often called *complementary slackness conditions*. These conditions can be exploited to solve for an optimal solution of the primal problem with the help of the dual problem, and conversely. Indeed, if we guess a solution to one problem, then we may solve for a solution of the dual using the complementary slackness conditions, and then check that our guess was correct. This is the essence of the *primal-dual* method. To present this method, first we need to take a closer look at the dual of a linear program already in standard form.

47.4 Duality for Linear Programs in Standard Form

Let (P) be a linear program in standard form, where $Ax = b$ for some $m \times n$ matrix of rank m and some objective function $x \mapsto cx$ (of course, $x \geq 0$). To obtain the dual of (P) we convert the equations $Ax = b$ to the following system of inequalities involving a $(2m) \times n$ matrix:

$$\begin{pmatrix} A \\ -A \end{pmatrix} x \leq \begin{pmatrix} b \\ -b \end{pmatrix}.$$

Then if we denote the $2m$ dual variables by (y', y'') , with $y', y'' \in (\mathbb{R}^m)^*$, the dual of the above program is

$$\begin{aligned} & \text{minimize } y'b - y''b \\ & \text{subject to } (y' \ y'') \begin{pmatrix} A \\ -A \end{pmatrix} \geq c \text{ and } y', y'' \geq 0, \end{aligned}$$

where $y', y'' \in (\mathbb{R}^m)^*$, which is equivalent to

$$\begin{aligned} & \text{minimize } (y' - y'')b \\ & \text{subject to } (y' - y'')A \geq c \text{ and } y', y'' \geq 0, \end{aligned}$$

where $y', y'' \in (\mathbb{R}^m)^*$. If we write $y = y' - y''$, we find that the above linear program is equivalent to the following Linear Program (D):

$$\begin{aligned} & \text{minimize } yb \\ & \text{subject to } yA \geq c, \end{aligned}$$

where $y \in (\mathbb{R}^m)^*$. Observe that y is *not required* to be nonnegative; it is arbitrary.

Next we would like to know what is the version of Theorem 47.8 for a linear program already in standard form. This is very simple.

Theorem 47.12. *Consider the Linear Program (P2) in standard form*

$$\begin{aligned} & \text{maximize } cx \\ & \text{subject to } Ax = b \text{ and } x \geq 0, \end{aligned}$$

and its Dual (D) given by

$$\begin{aligned} & \text{minimize } yb \\ & \text{subject to } yA \geq c, \end{aligned}$$

where $y \in (\mathbb{R}^m)^$. If the simplex algorithm applied to the Linear Program (P2) terminates with an optimal solution (u^*, K^*) , where u^* is a basic feasible solution and K^* is a basis for u^* , then $y^* = c_{K^*} A_{K^*}^{-1}$ is an optimal solution for (D) such that $cu^* = y^*b$. Furthermore, if we assume that the simplex algorithm is started with a basic feasible solution (u_0, K_0) where $K_0 = (n-m+1, \dots, n)$ (the indices of the last m columns of A) and $A_{(n-m+1, \dots, n)} = I_m$ (the last m columns of A constitute the identity matrix I_m), then the optimal solution $y^* = c_{K^*} A_{K^*}^{-1}$ for (D) is given in terms of the reduced costs by*

$$y^* = c_{(n-m+1, \dots, n)} - (\bar{c}_{K^*})_{(n-m+1, \dots, n)},$$

and the $m \times m$ matrix consisting of last m columns and the last m rows of the final tableau is $A_{K^}^{-1}$.*

Proof. The proof of Theorem 47.8 applies with A instead of \widehat{A} , and we can show that

$$c_{K^*} A_{K^*}^{-1} A_{N^*} \geq c_{N^*},$$

and that $y^* = c_{K^*} A_{K^*}^{-1}$ satisfies, $c u^* = y^* b$, and

$$\begin{aligned} y^* A_{K^*} &= c_{K^*} A_{K^*}^{-1} A_{K^*} = c_{K^*}, \\ y^* A_{N^*} &= c_{K^*} A_{K^*}^{-1} A_{N^*} \geq c_{N^*}. \end{aligned}$$

Let P be the $n \times n$ permutation matrix defined so that

$$AP = (A_{K^*} \quad A_{N^*}).$$

Then we also have

$$cP = (c_{K^*} \quad c_{N^*}),$$

and using the above equations and inequalities we obtain

$$y^* (A_{K^*} \quad A_{N^*}) \geq (c_{K^*} \quad c_{N^*}),$$

that is, $y^* AP \geq cP$, which is equivalent to

$$y^* A \geq c,$$

which shows that y^* is a feasible solution of (D) (remember, y^* is arbitrary so there is no need for the constraint $y^* \geq 0$).

The reduced costs are given by

$$(\bar{c}_{K^*})_i = c_i - c_{K^*} A_{K^*}^{-1} A^i,$$

and since for $j = n-m+1, \dots, n$ the column A^j is the $(j+m-n)$ th column of the identity matrix I_m , we have

$$(\bar{c}_{K^*})_j = c_j - (c_{K^*} A_{K^*}^{-1})_{j+m-n} \quad j = n-m+1, \dots, n,$$

that is,

$$y^* = c_{(n-m+1, \dots, n)} - (\bar{c}_{K^*})_{(n-m+1, \dots, n)},$$

as claimed. Since the last m rows of the final tableau is obtained by multiplying $[u_0 \ A]$ by $A_{K^*}^{-1}$, and the last m columns of A constitute I_m , the last m rows and the last m columns of the final tableau constitute $A_{K^*}^{-1}$. \square

Let us now take a look at the complementary slackness conditions of Theorem 47.11. If we go back to the version of (P) given by

$$\begin{aligned} &\text{maximize} \quad cx \\ &\text{subject to} \quad \begin{pmatrix} A \\ -A \end{pmatrix} x \leq \begin{pmatrix} b \\ -b \end{pmatrix} \quad \text{and} \quad x \geq 0, \end{aligned}$$

and to the version of (D) given by

$$\begin{aligned} & \text{minimize} \quad y'b - y''b \\ & \text{subject to} \quad (y' \ y'') \begin{pmatrix} A \\ -A \end{pmatrix} \geq c \text{ and } y', y'' \geq 0, \end{aligned}$$

where $y', y'' \in (\mathbb{R}^m)^*$, since the inequalities $Ax \leq b$ and $-Ax \leq -b$ together imply that $Ax = b$, we have equality for all these inequality constraints, and so the Conditions $(*_D)$ place no constraints at all on y' and y'' , while the Conditions $(*_P)$ assert that

$$x_j = 0 \quad \text{for all } j \text{ for which } \sum_{i=1}^m (y'_i - y''_i) a_{ij} > c_j.$$

If we write $y = y' - y''$, the above conditions are equivalent to

$$x_j = 0 \quad \text{for all } j \text{ for which } \sum_{i=1}^m y_i a_{ij} > c_j.$$

Thus we have the following version of Theorem 47.11.

Theorem 47.13. (Equilibrium Theorem, Version 2) *For any Linear Program $(P2)$ in standard form (with $Ax = b$ where A is an $m \times n$ matrix, $x \geq 0$, and objective function $x \mapsto cx$) and its Dual Linear Program (D) , for any feasible solution x of (P) and any feasible solution y of (D) , x and y are optimal solutions iff*

$$x_j = 0 \quad \text{for all } j \text{ for which } \sum_{i=1}^m y_i a_{ij} > c_j. \quad (*_P)$$

Therefore, the slackness conditions applied to a Linear Program $(P2)$ in standard form and to its Dual (D) *only impose slackness conditions on the variables x_j of the primal problem.*

The above fact plays a crucial role in the primal-dual method.

47.5 The Dual Simplex Algorithm

Given a Linear Program $(P2)$ in standard form

$$\begin{aligned} & \text{maximize} \quad cx \\ & \text{subject to} \quad Ax = b \text{ and } x \geq 0, \end{aligned}$$

where A is an $m \times n$ matrix of rank m , if no obvious feasible solution is available *but if $c \leq 0$* , rather than using the method for finding a feasible solution described in Section 46.2 we may use a method known as the dual simplex algorithm. This method uses basic solutions (u, K) where $Au = b$ and $u_j = 0$ for all $u_j \notin K$, but does not require $u \geq 0$, so u may not be feasible. However, $y = c_K A_K^{-1}$ is required to be feasible for the dual program

$$\begin{aligned} & \text{minimize} \quad yb \\ & \text{subject to} \quad yA \geq c, \end{aligned}$$

where $y \in (\mathbb{R}^*)^m$. Since $c \leq 0$, observe that $y = 0_m^\top$ is a feasible solution of the dual.

If a basic solution u of $(P2)$ is found such that $u \geq 0$, then $cu = yb$ for $y = c_K A_K^{-1}$, and we have found an optimal solution u for $(P2)$ and y for (D) . The dual simplex method makes progress by attempting to make negative components of u zero and by decreasing the objective function of the dual program.

The dual simplex method starts with a basic solution (u, K) of $Ax = b$ which is not feasible but for which $y = c_K A_K^{-1}$ is dual feasible. In many cases the original linear program is specified by a set of inequalities $Ax \leq b$ with some $b_i < 0$, so by adding slack variables it is easy to find such basic solution u , and if in addition $c \leq 0$, then because the cost associated with slack variables is 0, we see that $y = 0$ is a feasible solution of the dual.

Given a basic solution (u, K) of $Ax = b$ (feasible or not), $y = c_K A_K^{-1}$ is dual feasible iff $c_K A_K^{-1} A \geq c$, and since $c_K A_K^{-1} A_K = c_K$, the inequality $c_K A_K^{-1} A \geq c$ is equivalent to $c_K A_K^{-1} A_N \geq c_N$, that is,

$$c_N - c_K A_K^{-1} A_N \leq 0, \quad (*_1)$$

where $N = \{1, \dots, n\} - K$. Equation $(*_1)$ is equivalent to

$$c_j - c_K \gamma_K^j \leq 0 \quad \text{for all } j \in N, \quad (*_2)$$

where $\gamma_K^j = A_K^{-1} A^j$. Recall that the notation \bar{c}_j is used to denote $c_j - c_K \gamma_K^j$, which is called the *reduced cost* of the variable x_j .

As in the simplex algorithm we need to decide which column A^k leaves the basis K and which column A^j enters the new basis K^+ , in such a way that $y^+ = c_{K^+} A_{K^+}^{-1}$ is a feasible solution of (D) , that is, $c_{N^+} - c_{K^+} A_{K^+}^{-1} A_{N^+} \leq 0$, where $N^+ = \{1, \dots, n\} - K^+$. We use Proposition 46.2 to decide which column k^- should leave the basis.

Suppose (u, K) is a solution of $Ax = b$ for which $y = c_K A_K^{-1}$ is dual feasible.

Case (A). If $u \geq 0$, then u is an optimal solution of $(P2)$.

Case (B). There is some $k \in K$ such that $u_k < 0$. In this case pick some $k^- \in K$ such that $u_{k^-} < 0$ (according to some pivot rule).

Case (B1). Suppose that $\gamma_{k^-}^j \geq 0$ for all $j \notin K$ (in fact, for all j , since $\gamma_{k^-}^j \in \{0, 1\}$ for all $j \in K$). If so, we claim that $(P2)$ is not feasible.

Indeed, let v be some basic feasible solution. We have $v \geq 0$ and $Av = b$, that is,

$$\sum_{j=1}^n v_j A^j = b,$$

so by multiplying both sides by A_K^{-1} and using the fact that by definition $\gamma_K^j = A_K^{-1} A^j$, we obtain

$$\sum_{j=1}^n v_j \gamma_K^j = A_K^{-1} b = u_K.$$

But recall that by hypothesis $u_{k^-} < 0$, yet $v_j \geq 0$ and $\gamma_{k^-}^j \geq 0$ for all j , so the component of index k^- is zero or positive on the left, and negative on the right, a contradiction. Therefore, $(P2)$ is indeed not feasible.

Case (B2). We have $\gamma_{k^-}^j < 0$ for some j .

We pick the column A^j entering the basis among those for which $\gamma_{k^-}^j < 0$. Since we assumed that $c_j - c_K \gamma_K^j \leq 0$ for all $j \in N$ by $(*_2)$, consider

$$\mu^+ = \max \left\{ -\frac{c_j - c_K \gamma_K^j}{\gamma_{k^-}^j} \mid \gamma_{k^-}^j < 0, j \in N \right\} = \max \left\{ -\frac{\bar{c}_j}{\gamma_{k^-}^j} \mid \gamma_{k^-}^j < 0, j \in N \right\} \leq 0,$$

and the set

$$N(\mu^+) = \left\{ j \in N \mid -\frac{\bar{c}_j}{\gamma_{k^-}^j} = \mu^+ \right\}.$$

We pick some index $j^+ \in N(\mu^+)$ as the index of the column entering the basis (using some pivot rule).

Recall that by hypothesis $c_i - c_K \gamma_K^i \leq 0$ for all $j \notin K$ and $c_i - c_K \gamma_K^i = 0$ for all $i \in K$. Since $\gamma_{k^-}^{j^+} < 0$, for any index i such that $\gamma_{k^-}^i \geq 0$, we have $-\gamma_{k^-}^i / \gamma_{k^-}^{j^+} \geq 0$, and since by Proposition 46.2

$$c_i - c_{K^+} \gamma_{K^+}^i = c_i - c_K \gamma_K^i - \frac{\gamma_{k^-}^i}{\gamma_{k^-}^{j^+}} (c_{j^+} - c_K \gamma_K^{j^+}),$$

we have $c_i - c_{K^+} \gamma_{K^+}^i \leq 0$. For any index i such that $\gamma_{k^-}^i < 0$, by the choice of $j^+ \in K^*$,

$$-\frac{c_i - c_K \gamma_K^i}{\gamma_{k^-}^i} \leq -\frac{c_{j^+} - c_K \gamma_K^{j^+}}{\gamma_{k^-}^{j^+}},$$

so

$$c_i - c_K \gamma_K^i - \frac{\gamma_{k^-}^i}{\gamma_{k^-}^{j^+}} (c_{j^+} - c_K \gamma_K^{j^+}) \leq 0,$$

and again, $c_i - c_{K^+} \gamma_{K^+}^i \leq 0$. Therefore, if we let $K^+ = (K - \{k^-\}) \cup \{j^+\}$, then $y^+ = c_{K^+} A_{K^+}^{-1}$ is dual feasible. As in the simplex algorithm, θ^+ is given by

$$\theta^+ = u_{k^-} / \gamma_{k^-}^{j^+} \geq 0,$$

and u^+ is also computed as in the simplex algorithm by

$$u_i^+ = \begin{cases} u_i - \theta^{j^+} \gamma_i^{j^+} & \text{if } i \in K \\ \theta^{j^+} & \text{if } i = j^+ \\ 0 & \text{if } i \notin K \cup \{j^+\} \end{cases}.$$

The change in the objective function of the primal and dual program (which is the same, since $u_K = A_K^{-1}b$ and $y = c_K A_K^{-1}$ is chosen such that $cu = c_K u_K = yb$) is the same as in the simplex algorithm, namely

$$\theta^+ \left(c^{j^+} - c_K \gamma_K^{j^+} \right).$$

We have $\theta^+ > 0$ and $c^{j^+} - c_K \gamma_K^{j^+} \leq 0$, so if $c^{j^+} - c_K \gamma_K^{j^+} < 0$, then the objective function of the dual program decreases strictly.

Case (B3). $\mu^+ = 0$.

The possibility that $\mu^+ = 0$, that is, $c^{j^+} - c_K \gamma_K^{j^+} = 0$, may arise. In this case, the objective function doesn't change. This is a case of degeneracy similar to the degeneracy that arises in the simplex algorithm. We still pick $j^+ \in N(\mu^+)$, but we need a pivot rule that prevents cycling. Such rules exist; see Bertsimas and Tsitsiklis [21] (Section 4.5) and Papadimitriou and Steiglitz [134] (Section 3.6).

The reader surely noticed that the dual simplex algorithm is very similar to the simplex algorithm, except that the simplex algorithm preserves the property that (u, K) is (primal) feasible, whereas the dual simplex algorithm preserves the property that $y = c_K A_K^{-1}$ is dual feasible. One might then wonder whether the dual simplex algorithm is equivalent to the simplex algorithm applied to the dual problem. This is indeed the case, there is a one-to-one correspondence between the dual simplex algorithm and the simplex algorithm applied to the dual problem in maximization form. This correspondence is described in Papadimitriou and Steiglitz [134] (Section 3.7).

The comparison between the simplex algorithm and the dual simplex algorithm is best illustrated if we use a description of these methods in terms of (*full*) *tableaux*.

Recall that a (*full*) *tableau* is an $(m + 1) \times (n + 1)$ matrix organized as follows:

$-c_K u_K$	\bar{c}_1	\cdots	\bar{c}_j	\cdots	\bar{c}_n
u_{k_1}	γ_1^1	\cdots	γ_1^j	\cdots	γ_1^n
\vdots	\vdots		\vdots		\vdots
u_{k_m}	γ_m^1	\cdots	γ_m^j	\cdots	γ_m^n

The top row contains the current value of the objective function and the reduced costs, the first column except for its top entry contain the components of the current basic solution u_K , and the remaining columns except for their top entry contain the vectors γ_K^j . Observe that the γ_K^j corresponding to indices j in K constitute a permutation of the identity matrix I_m . A tableau together with the new basis $K^+ = (K - \{k^-\}) \cup \{j^+\}$ contains all the data needed to compute the new u_{K^+} , the new $\gamma_{K^+}^j$, and the new reduced costs $\bar{c}_i - (\gamma_{k^-}^i / \gamma_{k^-}^{j^+}) \bar{c}_{j^+}$.

When executing the simplex algorithm, we have $u_k \geq 0$ for all $k \in K$ (and $u_j = 0$ for all $j \notin K$), and the incoming column j^+ is determined by picking one of the column indices such that $\bar{c}_j > 0$. Then the index k^- of the leaving column is determined by looking at the minimum of the ratios $u_k / \gamma_k^{j^+}$ for which $\gamma_k^{j^+} > 0$ (along column j^+).

On the other hand, when executing the dual simplex algorithm, we have $\bar{c}_j \leq 0$ for all $j \notin K$ (and $\bar{c}_k = 0$ for all $k \in K$), and the outgoing column k^- is determined by picking one of the row indices such that $u_k < 0$. The index j^+ of the incoming column is determined by looking at the maximum of the ratios $-\bar{c}_j/\gamma_{k^-}^j$ for which $\gamma_{k^-}^j < 0$ (along row k^-).

More details about the comparison between the simplex algorithm and the dual simplex algorithm can be found in Bertsimas and Tsitsiklis [21] and Papadimitriou and Steiglitz [134].

Here is an example of the the dual simplex method.

Example 47.2. Consider the following linear program in standard form:

$$\text{Maximize} \quad -4x_1 - 2x_2 - x_3$$

$$\text{subject to} \quad \begin{pmatrix} -1 & -1 & 2 & 1 & 0 & 0 \\ -4 & -2 & 1 & 0 & 1 & 0 \\ 1 & 1 & -4 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \\ x_6 \end{pmatrix} = \begin{pmatrix} -3 \\ -4 \\ 2 \end{pmatrix} \text{ and } x_1, x_2, x_3, x_4, x_5, x_6 \geq 0.$$

We initialize the dual simplex procedure with (u, K) where $u = \begin{pmatrix} 0 \\ 0 \\ 0 \\ -3 \\ -4 \\ 2 \end{pmatrix}$ and $K = (4, 5, 6)$.

The initial tableau, before explicitly calculating the reduced cost, is

0	\bar{c}_1	\bar{c}_2	\bar{c}_3	\bar{c}_4	\bar{c}_5	\bar{c}_6
$u_4 = -3$	-1	-1	2	1	0	0
$u_5 = -4$	-4	-2	1	0	1	0
$u_6 = 2$	1	1	-4	0	0	1

.

Since u has negative coordinates, Case (B) applies, and we will set $k^- = 4$. We must now determine whether Case (B1) or Case (B2) applies. This determination is accomplished by scanning the first three columns in the tableau and observing each column has a negative entry. Thus Case (B2) is applicable, and we need to determine the reduced costs. Observe that $c = (-4, -2, -1, 0, 0, 0)$, which in turn implies $c_{(4,5,6)} = (0, 0, 0)$. Equation $(*_2)$ implies

that the nonzero reduced costs are

$$\begin{aligned}\bar{c}_1 &= c_1 - c_{(4,5,6)} \begin{pmatrix} -1 \\ -4 \\ 1 \end{pmatrix} = -4 \\ \bar{c}_2 &= c_2 - c_{(4,5,6)} \begin{pmatrix} -1 \\ -2 \\ 1 \end{pmatrix} = -2 \\ \bar{c}_3 &= c_3 - c_{(4,5,6)} \begin{pmatrix} -2 \\ 1 \\ 4 \end{pmatrix} = -1,\end{aligned}$$

and our tableau becomes

0	-4	-2	-1	0	0	0
$u_4 = -3$	-1	(-1)	2	1	0	0
$u_5 = -4$	-4	-2	1	0	1	0
$u_6 = 2$	1	1	-4	0	0	1

.

Since $k^- = 4$, our pivot row is the first row of the tableau. To determine candidates for j^+ , we scan this row, locate negative entries and compute

$$\mu^+ = \max \left\{ -\frac{\bar{c}_j}{\gamma_4^j} \mid \gamma_4^j < 0, j \in \{1, 2, 3\} \right\} = \max \left\{ \frac{-2}{1}, \frac{-4}{1} \right\} = -2.$$

Since μ^+ occurs when $j = 2$, we set $j^+ = 2$. Our new basis is $K^+ = (2, 5, 6)$. We must normalize the first row of the tableau, namely multiply by -1 , then add twice this normalized row to the second row, and subtract the normalized row from the third row to obtain the updated tableau.

0	-4	-2	-1	0	0	0
$u_2 = 3$	1	(1)	-2	-1	0	0
$u_5 = 2$	-2	0	-3	-2	1	0
$u_6 = -1$	0	0	-2	1	0	1

It remains to update the reduced costs and the value of the objective function by adding twice the normalized row to the top row.

6	-2	0	-5	-2	0	0
$u_2 = 3$	1	1	-2	-1	0	0
$u_5 = 2$	-2	0	-3	-2	1	0
$u_6 = -1$	0	0	(-2)	1	0	1

We now repeat the procedure of Case (B2) and set $k^- = 6$ (since this is the only negative entry of u^+). Our pivot row is now the third row of the updated tableau, and the new μ^+

becomes

$$\mu^+ = \max \left\{ -\frac{\bar{c}_j}{\gamma_6^j} \mid \gamma_6^j < 0, j \in \{1, 3, 4\} \right\} = \max \left\{ \frac{-5}{2} \right\} = -\frac{5}{2},$$

which implies that $j^+ = 3$. Hence the new basis is $K^+ = (2, 5, 3)$, and we update the tableau by taking $-\frac{1}{2}$ of Row 3, adding twice the normalized Row 3 to Row 1, and adding three times the normalized Row 3 to Row 2.

6	-2	0	-5	-2	0	0
$u_2 = 4$	1	1	0	-2	0	-1
$u_5 = 7/2$	-2	0	0	$-7/2$	1	$-3/2$
$u_3 = 1/2$	0	0	(1)	$-1/2$	0	$-1/2$

It remains to update the objective function and the reduced costs by adding five times the normalized row to the top row.

17/2	-2	0	0	$-9/2$	0	$-5/2$
$u_2 = 4$	1	1	0	-2	0	-1
$u_5 = 7/2$	-2	0	0	$-\frac{7}{2}$	1	$-3/2$
$u_3 = 1/2$	0	0	(1)	$-1/2$	0	$-1/2$

Since u^+ has no negative entries, the dual simplex method terminates and objective function $-4x_1 - 2x_2 - x_3$ is maximized with $-\frac{17}{2}$ at $(0, 4, \frac{1}{2})$. See Figure 47.5.

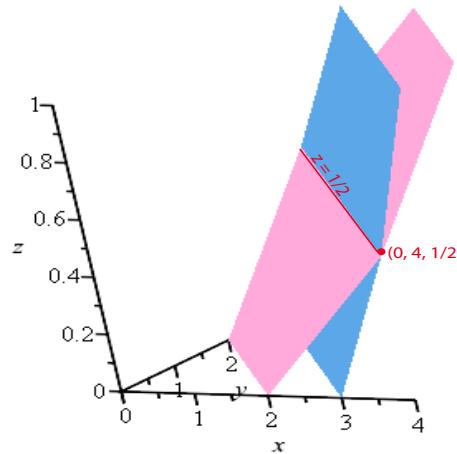

Figure 47.5: The objective function $-4x_1 - 2x_2 - x_3$ is maximized at the intersection between the blue plane $-x_1 - x_2 + 2x_3 = -3$ and the pink plane $x_1 + x_2 - 4x_3 = 2$.

47.6 The Primal-Dual Algorithm

Let $(P2)$ be a linear program in standard form

$$\begin{aligned} & \text{maximize} && cx \\ & \text{subject to} && Ax = b \text{ and } x \geq 0, \end{aligned}$$

where A is an $m \times n$ matrix of rank m , and (D) be its dual given by

$$\begin{aligned} & \text{minimize} && yb \\ & \text{subject to} && yA \geq c, \end{aligned}$$

where $y \in (\mathbb{R}^m)^*$.

First we may assume that $b \geq 0$ by changing every equation $\sum_{j=1}^n a_{ij}x_j = b_i$ with $b_i < 0$ to $\sum_{j=1}^n -a_{ij}x_j = -b_i$. If we happen to have some feasible solution y of the dual program (D) , we know from Theorem 47.13 that a feasible solution x of $(P2)$ is an optimal solution iff the equations in $(*_P)$ hold. If we denote by J the subset of $\{1, \dots, n\}$ for which the equalities

$$yA^j = c_j$$

hold, then by Theorem 47.13 a feasible solution x of $(P2)$ is an optimal solution iff

$$x_j = 0 \quad \text{for all } j \notin J.$$

Let $|J| = p$ and $N = \{1, \dots, n\} - J$. The above suggests looking for $x \in \mathbb{R}^n$ such that

$$\begin{aligned} \sum_{j \in J} x_j A^j &= b \\ x_j &\geq 0 \quad \text{for all } j \in J \\ x_j &= 0 \quad \text{for all } j \notin J, \end{aligned}$$

or equivalently

$$A_J x_J = b, \quad x_J \geq 0, \tag{*_1}$$

and

$$x_N = 0_{n-p}.$$

To search for such an x , we just need to look for a feasible x_J , and for this we can use the *Restricted Primal* linear program (RP) defined as follows:

$$\begin{aligned} & \text{maximize} && -(\xi_1 + \dots + \xi_m) \\ & \text{subject to} && (A_J \quad I_m) \begin{pmatrix} x_J \\ \xi \end{pmatrix} = b \text{ and } x, \xi \geq 0. \end{aligned}$$

Since by hypothesis $b \geq 0$ and the objective function is bounded above by 0, this linear program has an optimal solution (x_J^*, ξ^*) .

If $\xi^* = 0$, then the vector $u^* \in \mathbb{R}^n$ given by $u_J^* = x_J^*$ and $u_N^* = 0_{n-p}$ is an optimal solution of (P) .

Otherwise, $\xi^* > 0$ and we have failed to solve $(*_1)$. However we may try to use ξ^* to improve y . For this consider the Dual (*DRP*) of (*RP*):

$$\begin{aligned} &\text{minimize} && z b \\ &\text{subject to} && z A_J \geq 0 \\ & && z \geq -\mathbf{1}_m^\top. \end{aligned}$$

Observe that the Program (*DRP*) has the same objective function as the original Dual Program (*D*). We know by Theorem 47.12 that the optimal solution (x_J^*, ξ^*) of (*RP*) yields an optimal solution z^* of (*DRP*) such that

$$z^* b = -(\xi_1^* + \dots + \xi_m^*) < 0.$$

In fact, if K^* is the basis associated with (x_J^*, ξ^*) and if we write

$$\widehat{A} = (A_J \quad I_m)$$

and $\widehat{c} = [0_p^\top \quad -\mathbf{1}^\top]$, then by Theorem 47.12 we have

$$z^* = \widehat{c}_{K^*} \widehat{A}_{K^*}^{-1} = -\mathbf{1}_m^\top - (\bar{c}_{K^*})_{(p+1, \dots, p+m)},$$

where $(\bar{c}_{K^*})_{(p+1, \dots, p+m)}$ denotes the row vector of reduced costs in the final tableau corresponding to the last m columns.

If we write

$$y(\theta) = y + \theta z^*,$$

then the new value of the objective function of (*D*) is

$$y(\theta)b = yb + \theta z^*b, \tag{*2}$$

and since $z^*b < 0$, we have a chance of improving the objective function of (*D*), that is, decreasing its value for $\theta > 0$ small enough if $y(\theta)$ is feasible for (*D*). This will be the case iff $y(\theta)A \geq c$ iff

$$yA + \theta z^*A \geq c. \tag{*3}$$

Now since y is a feasible solution of (*D*) we have $yA \geq c$, so if $z^*A \geq 0$, then $(*_3)$ is satisfied and $y(\theta)$ is a solution of (*D*) for all $\theta > 0$, which means that (*D*) is unbounded. But this implies that (P) is not feasible.

Let us take a closer look at the inequalities $z^* A \geq 0$. For $j \in J$, since z^* is an optimal solution of (DRP) , we know that $z^* A_J \geq 0$, so if $z^* A^j \geq 0$ for all $j \in N$, then $(P2)$ is not feasible.

Otherwise, there is some $j \in N = \{1, \dots, n\} - J$ such that

$$z^* A^j < 0,$$

and then since by the definition of N we have $y A^j > c_j$ for all $j \in N$, if we pick θ such that

$$0 < \theta \leq \frac{y A^j - c_j}{-z^* A^j} \quad j \in N, z^* A^j < 0,$$

then we decrease the objective function $y(\theta)b = yb + \theta z^* b$ of (D) (since $z^* b < 0$). Therefore we pick the best θ , namely

$$\theta^+ = \min \left\{ \frac{y A^j - c_j}{-z^* A^j} \mid j \notin J, z^* A^j < 0 \right\} > 0. \quad (*_4)$$

Next we update y to $y^+ = y(\theta^+) = y + \theta^+ z^*$, we create the new restricted primal with the new subset

$$J^+ = \{j \in \{1, \dots, n\} \mid y^+ A^j = c_j\},$$

and repeat the process.

Here are the steps of the primal-dual algorithm.

Step 1. Find some feasible solution y of the Dual Program (D) . We will show later that this is always possible.

Step 2. Compute

$$J^+ = \{j \in \{1, \dots, n\} \mid y A^j = c_j\}.$$

Step 3. Set $J = J^+$ and solve the Problem (RP) using the simplex algorithm, starting from the optimal solution determined during the previous round, obtaining the optimal solution (x_J^*, ξ^*) with the basis K^* .

Step 4.

If $\xi^* = 0$, then stop with an optimal solution u^* for (P) such that $u_J^* = x_J^*$ and the other components of u^* are zero.

Else let

$$z^* = -\mathbf{1}_m^\top - (\bar{c}_{K^*})_{(p+1, \dots, p+m)},$$

be the optimal solution of (DRP) corresponding to (x_J^*, ξ^*) and the basis K^* .

If $z^* A^j \geq 0$ for all $j \notin J$, then stop; the Program (P) has no feasible solution.

Else compute

$$\theta^+ = \min \left\{ -\frac{y A^j - c_j}{z^* A^j} \mid j \notin J, z^* A^j < 0 \right\}, \quad y^+ = y + \theta^+ z^*,$$

and

$$J^+ = \{j \in \{1, \dots, n\} \mid y^+ A^j = c_j\}.$$

Go back to Step 3.

The following proposition shows that at each iteration we can start the Program (*RP*) with the optimal solution obtained at the previous iteration.

Proposition 47.14. *Every $j \in J$ such that A^j is in the basis of the optimal solution ξ^* belongs to the next index set J^+ .*

Proof. Such an index $j \in J$ correspond to a variable ξ_j such that $\xi_j > 0$, so by complementary slackness, the constraint $z^* A^j \geq 0$ of the Dual Program (*DRP*) must be an equality, that is, $z^* A^j = 0$. But then we have

$$y^+ A^j = y A^j + \theta^+ z^* A^j = c_j,$$

which shows that $j \in J^+$. □

If (u^*, ξ^*) with the basis K^* is the optimal solution of the Program (*RP*), Proposition 47.14 together with the last property of Theorem 47.12 allows us to restart the (*RP*) in Step 3 with $(u^*, \xi^*)_{K^*}$ as initial solution (with basis K^*). For every $j \in J - J^+$, column j is deleted, and for every $j \in J^+ - J$, the new column A^j is computed by multiplying $\widehat{A}_{K^*}^{-1}$ and A^j , but $\widehat{A}_{K^*}^{-1}$ is the matrix $\Gamma^*[1:m; p+1:p+m]$ consisting of the last m columns of Γ^* in the final tableau, and the new reduced \bar{c}_j is given by $c_j - z^* A^j$. Reusing the optimal solution of the previous (*RP*) may improve efficiency significantly.

Another crucial observation is that for any index $j_0 \in N$ such that $\theta^+ = (y A^{j_0} - c_{j_0}) / (-z^* A^{j_0})$, we have

$$y^+ A_{j_0} = y A_{j_0} + \theta^+ z^* A^{j_0} = c_{j_0},$$

and so $j_0 \in J^+$. This fact that be used to ensure that the primal-dual algorithm terminates in a finite number of steps (using a pivot rule that prevents cycling); see Papadimitriou and Steiglitz [134] (Theorem 5.4).

It remains to discuss how to pick some initial feasible solution y of the Dual Program (*D*). If $c_j \leq 0$ for $j = 1, \dots, n$, then we can pick $y = 0$. If we are dealing with a minimization problem, the weight c_j are often nonnegative, so from the point of view of maximization we will have $-c_j \leq 0$ for all j , and we will be able to use $y = 0$ as a starting point.

Going back to our primal problem in maximization form and its dual in minimization form, we still need to deal with the situation where $c_j > 0$ for some j , in which case there

may not be any obvious y feasible for (D) . Preferably we would like to find such a y very cheaply.

There is a trick to deal with this situation. We pick some very large positive number M and add to the set of equations $Ax = b$ the new equation

$$x_1 + \cdots + x_n + x_{n+1} = M,$$

with the new variable x_{n+1} constrained to be nonnegative. If the Program (P) has a feasible solution, such an M exists. In fact it can be shown that for any basic feasible solution $u = (u_1, \dots, u_n)$, each $|u_i|$ is bounded by some expression depending only on A and b ; see Papadimitriou and Steiglitz [134] (Lemma 2.1). The proof is not difficult and relies on the fact that the inverse of a matrix can be expressed in terms of certain determinants (the adjugates). Unfortunately, this bound contains $m!$ as a factor, which makes it quite impractical.

Having added the new equation above, we obtain the new set of equations

$$\begin{pmatrix} A & 0_n \\ \mathbf{1}_n^\top & 1 \end{pmatrix} \begin{pmatrix} x \\ x_{n+1} \end{pmatrix} = \begin{pmatrix} b \\ M \end{pmatrix},$$

with $x \geq 0, x_{n+1} \geq 0$, and the new objective function given by

$$(c \ 0) \begin{pmatrix} x \\ x_{n+1} \end{pmatrix} = cx.$$

The dual of the above linear program is

$$\begin{aligned} & \text{minimize} && yb + y_{m+1}M \\ & \text{subject to} && yA^j + y_{m+1} \geq c_j \quad j = 1, \dots, n \\ & && y_{m+1} \geq 0. \end{aligned}$$

If $c_j > 0$ for some j , observe that the linear form \tilde{y} given by

$$\tilde{y}_i = \begin{cases} 0 & \text{if } 1 \leq i \leq m \\ \max_{1 \leq j \leq n} \{c_j\} > 0 \end{cases}$$

is a feasible solution of the new dual program. In practice, we can choose M to be a number close to the largest integer representable on the computer being used.

Here is an example of the primal-dual algorithm given in the Math 588 class notes of T. Molla [128].

Example 47.3. Consider the following linear program in standard form:

$$\begin{aligned} & \text{Maximize} && -x_1 - 3x_2 - 3x_3 - x_4 \\ & \text{subject to} && \begin{pmatrix} 3 & 4 & -3 & 1 \\ 3 & -2 & 6 & -1 \\ 6 & 4 & 0 & 1 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix} = \begin{pmatrix} 2 \\ 1 \\ 4 \end{pmatrix} \quad \text{and } x_1, x_2, x_3, x_4 \geq 0. \end{aligned}$$

The associated Dual Program (D) is

$$\begin{aligned} \text{Minimize} \quad & 2y_1 + y_2 + 4y_3 \\ \text{subject to} \quad & (y_1 \ y_2 \ y_3) \begin{pmatrix} 3 & 4 & -3 & 1 \\ 3 & -2 & 6 & -1 \\ 6 & 4 & 0 & 1 \end{pmatrix} \geq (-1 \ -3 \ -3 \ -1). \end{aligned}$$

We initialize the primal-dual algorithm with the dual feasible point $y = (-1/3 \ 0 \ 0)$. Observe that only the first inequality of (D) is actually an equality, and hence $J = \{1\}$. We form the Restricted Primal Program ($RP1$)

$$\begin{aligned} \text{Maximize} \quad & -(\xi_1 + \xi_2 + \xi_3) \\ \text{subject to} \quad & \begin{pmatrix} 3 & 1 & 0 & 0 \\ 3 & 0 & 1 & 0 \\ 6 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} x_1 \\ \xi_1 \\ \xi_2 \\ \xi_3 \end{pmatrix} = \begin{pmatrix} 2 \\ 1 \\ 4 \end{pmatrix} \text{ and } x_1, \xi_1, \xi_2, \xi_3 \geq 0. \end{aligned}$$

We now solve ($RP1$) via the simplex algorithm. The initial tableau with $K = (2, 3, 4)$ and $J = \{1\}$ is

	x_1	ξ_1	ξ_2	ξ_3
7	12	0	0	0
$\xi_1 = 2$	3	1	0	0
$\xi_2 = 1$	3	0	1	0
$\xi_3 = 4$	6	0	0	1

.

For ($RP1$), $\hat{c} = (0, -1, -1, -1)$, $(x_1, \xi_1, \xi_2, \xi_3) = (0, 2, 1, 4)$, and the nonzero reduced cost is given by

$$0 - (-1 \ -1 \ -1) \begin{pmatrix} 3 \\ 3 \\ 6 \end{pmatrix} = 12.$$

Since there is only one nonzero reduced cost, we must set $j^+ = 1$. Since $\min\{\xi_1/3, \xi_2/3, \xi_3/6\} = 1/3$, we see that $k^- = 3$ and $K = (2, 1, 4)$. Hence we pivot through the red circled 3 (namely we divide row 2 by 3, and then subtract $3 \times$ (row 2) from row 1, $6 \times$ (row 2) from row 3, and $12 \times$ (row 2) from row 0), to obtain the tableau

	x_1	ξ_1	ξ_2	ξ_3
3	0	0	-4	0
$\xi_1 = 1$	0	1	-1	0
$x_1 = 1/3$	1	0	1/3	0
$\xi_3 = 2$	0	0	-2	1

.

At this stage the simplex algorithm for ($RP1$) terminates since there are no positive reduced costs. Since the upper left corner of the final tableau is not zero, we proceed with Step 4 of the primal dual algorithm and compute

$$z^* = (-1 \ -1 \ -1) - (0 \ -4 \ 0) = (-1 \ 3 \ -1),$$

$$yA^2 - c_2 = (-1/3 \ 0 \ 0) \begin{pmatrix} 4 \\ -2 \\ 4 \end{pmatrix} + 3 = \frac{5}{3}, \quad z^*A^2 = -(-1 \ 3 \ -1) \begin{pmatrix} 4 \\ -2 \\ 4 \end{pmatrix} = 14,$$

$$yA^4 - c_4 = (-1/3 \ 0 \ 0) \begin{pmatrix} 1 \\ -1 \\ 1 \end{pmatrix} + 1 = \frac{2}{3}, \quad z^*A^4 = -(-1 \ 3 \ -1) \begin{pmatrix} 1 \\ -1 \\ 1 \end{pmatrix} = 5,$$

so

$$\theta^+ = \min \left\{ \frac{5}{42}, \frac{2}{15} \right\} = \frac{5}{42},$$

and we conclude that the new feasible solution for (D) is

$$y^+ = (-1/3 \ 0 \ 0) + \frac{5}{42}(-1 \ 3 \ -1) = (-19/42 \ 5/14 \ -5/42).$$

When we substitute y^+ into (D) , we discover that the first two constraints are equalities, and that the new J is $J = \{1, 2\}$. The new Reduced Primal $(RP2)$ is

$$\begin{aligned} \text{Maximize} \quad & -(\xi_1 + \xi_2 + \xi_3) \\ \text{subject to} \quad & \begin{pmatrix} 3 & 4 & 1 & 0 & 0 \\ 3 & -2 & 0 & 1 & 0 \\ 6 & 4 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ \xi_1 \\ \xi_2 \\ \xi_3 \end{pmatrix} = \begin{pmatrix} 2 \\ 1 \\ 4 \end{pmatrix} \text{ and } x_1, x_2, \xi_1, \xi_2, \xi_3 \geq 0. \end{aligned}$$

Once again, we solve $(RP2)$ via the simplex algorithm, where $\hat{c} = (0, 0, -1, -1, -1)$, $(x_1, x_2, \xi_1, \xi_2, \xi_3) = (1/3, 0, 1, 0, 2)$ and $K = (3, 1, 5)$. The initial tableau is obtained from the final tableau of the previous $(RP1)$ by adding a column corresponding to the variable x_2 , namely

$$\widehat{A}_K^{-1} A^2 = \begin{pmatrix} 1 & -1 & 0 \\ 0 & 1/3 & 0 \\ 0 & -2 & 1 \end{pmatrix} \begin{pmatrix} 4 \\ -2 \\ 4 \end{pmatrix} = \begin{pmatrix} 6 \\ -2/3 \\ 8 \end{pmatrix},$$

with

$$\bar{c}_2 = c_2 - z^*A^2 = 0 - (-1 \ 3 \ -1) \begin{pmatrix} 4 \\ -2 \\ 4 \end{pmatrix} = 14,$$

and we get

	x_1	x_2	ξ_1	ξ_2	ξ_3
3	0	14	0	-4	0
$\xi_1 = 1$	0	6	1	-1	0
$x_1 = 1/3$	1	-2/3	0	1/3	0
$\xi_3 = 2$	0	8	0	-2	1

Note that $j^+ = 2$ since the only positive reduced cost occurs in column 2. Also observe that since $\min\{\xi_1/6, \xi_3/8\} = \xi_1/6 = 1/6$, we set $k^- = 3$, $K = (2, 1, 5)$ and pivot along the red 6 to obtain the tableau

	x_1	x_2	ξ_1	ξ_2	ξ_3
$2/3$	0	0	$-7/3$	$-5/3$	0
$x_2 = 1/6$	0	1	$1/6$	$-1/6$	0
$x_1 = 4/9$	1	0	$1/9$	$2/9$	0
$\xi_3 = 2/3$	0	0	$-4/3$	$-2/3$	1

Since the reduced costs are either zero or negative the simplex algorithm terminates, and we compute

$$z^* = (-1 \ -1 \ -1) - (-7/3 \ -5/3 \ 0) = (4/3 \ 2/3 \ -1),$$

$$y^+ A^4 - c_4 = (-19/42 \ 5/14 \ -5/42) \begin{pmatrix} 1 \\ -1 \\ 1 \end{pmatrix} + 1 = 1/14,$$

$$z^* A^4 = -(4/3 \ 2/3 \ -1) \begin{pmatrix} 1 \\ -1 \\ 1 \end{pmatrix} = 1/3,$$

so

$$\theta^+ = \frac{3}{14},$$

$$y^+ = (-19/42 \ 5/14 \ -5/42) + \frac{5}{14}(4/3 \ 2/3 \ -1) = (-1/6 \ 1/2 \ -1/3).$$

When we plug y^+ into (D) , we discover that the first, second, and fourth constraints are equalities, which implies $J = \{1, 2, 4\}$. Hence the new Restricted Primal $(RP3)$ is

$$\begin{aligned} \text{Maximize} \quad & -(\xi_1 + \xi_2 + \xi_3) \\ \text{subject to} \quad & \begin{pmatrix} 3 & 4 & 1 & 1 & 0 & 0 \\ 3 & -2 & -1 & 0 & 1 & 0 \\ 6 & 4 & 1 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_4 \\ \xi_1 \\ \xi_2 \\ \xi_3 \end{pmatrix} = \begin{pmatrix} 2 \\ 1 \\ 4 \end{pmatrix} \quad \text{and } x_1, x_2, x_4, \xi_1, \xi_2, \xi_3 \geq 0. \end{aligned}$$

The initial tableau for $(RP3)$, with $\hat{c} = (0, 0, 0, -1, -1, -1)$, $(x_1, x_2, x_4, \xi_1, \xi_2, \xi_3) = (4/9, 1/6, 0, 0, 0, 2/3)$ and $K = (2, 1, 6)$, is obtained from the final tableau of the previous $(RP2)$ by adding a column corresponding the the variable x_4 , namely

$$\widehat{A}_K^{-1} A^4 = \begin{pmatrix} 1/6 & -1/6 & 0 \\ 1/9 & 2/9 & 0 \\ -4/3 & -2/3 & 1 \end{pmatrix} \begin{pmatrix} 1 \\ -1 \\ 1 \end{pmatrix} = \begin{pmatrix} 1/3 \\ -1/9 \\ 1/3 \end{pmatrix},$$

with

$$\bar{c}_4 = c_4 - z^* A^4 = 0 - (4/3 \quad 2/3 \quad -1) \begin{pmatrix} 1 \\ -1 \\ 1 \end{pmatrix} = 1/3,$$

and we get

	x_1	x_2	x_4	ξ_1	ξ_2	ξ_3
$2/3$	0	0	$1/3$	$-7/3$	$-5/3$	0
$x_2 = 1/6$	0	1	$1/3$	$1/6$	$-1/6$	0
$x_1 = 4/9$	1	0	$-1/9$	$1/9$	$2/9$	0
$\xi_3 = 2/3$	0	0	$1/3$	$-4/3$	$-2/3$	1

Since the only positive reduced cost occurs in column 3, we set $j^+ = 3$. Furthermore since $\min\{x_2/(1/3), \xi_3/(1/3)\} = x_2/(1/3) = 1/2$, we let $k^- = 2$, $K = (3, 1, 6)$, and pivot around the red circled $1/3$ to obtain

	x_1	x_2	x_4	ξ_1	ξ_2	ξ_3
$1/2$	0	-1	0	$-5/2$	$-3/2$	0
$x_4 = 1/2$	0	3	1	$1/2$	$-1/2$	0
$x_1 = 1/2$	1	$1/3$	0	$1/6$	$1/6$	0
$\xi_3 = 1/2$	0	-1	0	$-3/2$	$-1/2$	1

At this stage there are no positive reduced costs, and we must compute

$$z^* = (-1 \quad -1 \quad -1) - (-5/2 \quad -3/2 \quad 0) = (3/2 \quad 1/2 \quad -1),$$

$$y^+ A^3 - c_3 = (-1/6 \quad 1/2 \quad -1/3) \begin{pmatrix} -3 \\ 6 \\ 0 \end{pmatrix} + 3 = 13/2,$$

$$z^* A^3 = -(3/2 \quad 1/2 \quad -1) \begin{pmatrix} -3 \\ 6 \\ 0 \end{pmatrix} = 3/2,$$

so

$$\theta^+ = \frac{13}{3},$$

$$y^+ = (-1/6 \quad 1/2 \quad -1/3) + \frac{13}{3} (3/2 \quad 1/2 \quad -1) = (19/3 \quad 8/3 \quad -14/3).$$

We plug y^+ into (D) and discover that the first, third, and fourth constraints are equalities. Thus, $J = \{1, 3, 4\}$ and the Restricted Primal $(RP4)$ is

$$\begin{aligned} \text{Maximize} \quad & -(\xi_1 + \xi_2 + \xi_3) \\ \text{subject to} \quad & \begin{pmatrix} 3 & -3 & 1 & 1 & 0 & 0 \\ 3 & 6 & -1 & 0 & 1 & 0 \\ 6 & 0 & 1 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} x_1 \\ x_3 \\ x_4 \\ \xi_1 \\ \xi_2 \\ \xi_3 \end{pmatrix} = \begin{pmatrix} 2 \\ 1 \\ 4 \end{pmatrix} \text{ and } x_1, x_3, x_4, \xi_1, \xi_2, \xi_3 \geq 0. \end{aligned}$$

The initial tableau for $(RP4)$, with $\hat{c} = (0, 0, 0, -1, -1, -1)$, $(x_1, x_3, x_4, \xi_1, \xi_2, \xi_3) = (1/2, 0, 1/2, 0, 0, 1/2)$ and $K = (3, 1, 6)$ is obtained from the final tableau of the previous $(RP3)$ by replacing the column corresponding to the variable x_2 by a column corresponding to the variable x_3 , namely

$$\hat{A}_K^{-1} A^3 = \begin{pmatrix} 1/2 & -1/2 & 0 \\ 1/6 & 1/6 & 0 \\ -3/2 & -1/2 & 1 \end{pmatrix} \begin{pmatrix} -3 \\ 6 \\ 0 \end{pmatrix} = \begin{pmatrix} -9/2 \\ 1/2 \\ 3/2 \end{pmatrix},$$

with

$$\bar{c}_3 = c_3 - z^* A^3 = 0 - (3/2 \ 1/2 \ -1) \begin{pmatrix} -3 \\ 6 \\ 0 \end{pmatrix} = 3/2,$$

and we get

	x_1	x_3	x_4	ξ_1	ξ_2	ξ_3
$1/2$	0	$3/2$	0	$-5/2$	$-3/2$	0
$x_4 = 1/2$	0	$-9/2$	1	$1/2$	$-1/2$	0
$x_1 = 1/2$	1	$1/2$	0	$1/6$	$1/6$	0
$\xi_3 = 1/2$	0	3/2	0	$-3/2$	$-1/2$	1

By analyzing the top row of reduced cost, we see that $j^+ = 2$. Furthermore, since $\min\{x_1/(1/2), \xi_3/(3/2)\} = \xi_3/(3/2) = 1/3$, we let $k^- = 6$, $K = (3, 1, 2)$, and pivot along the red circled $3/2$ to obtain

	x_1	x_3	x_4	ξ_1	ξ_2	ξ_3
0	0	0	0	-1	-1	-1
$x_4 = 2$	0	0	1	-4	-2	3
$x_1 = 1/3$	1	0	0	$2/3$	$1/3$	$-1/3$
$x_3 = 1/3$	0	1	0	-1	$-1/3$	$2/3$

Since the upper left corner of the final tableau is zero and the reduced costs are all ≤ 0 , we are finally finished. Then $y = (19/3 \ 8/3 \ -14/3)$ is an optimal solution of (D) , but more

importantly $(x_1, x_2, x_3, x_4) = (1/3, 0, 1/3, 2)$ is an optimal solution for our original linear program and provides an optimal value of $-10/3$.

The primal-dual algorithm for linear programming doesn't seem to be the favorite method to solve linear programs nowadays. But it is important because its basic principle, to use a restricted (simpler) primal problem involving an objective function with fixed weights, namely 1, and the dual problem to provide feedback to the primal by improving the objective function of the dual, has led to a whole class of combinatorial algorithms (often approximation algorithms) based on the primal-dual paradigm. The reader will get a taste of this kind of algorithm by consulting Papadimitriou and Steiglitz [134], where it is explained how classical algorithms such as Dijkstra's algorithm for the shortest path problem, and Ford and Fulkerson's algorithm for max flow can be derived from the primal-dual paradigm.

47.7 Summary

The main concepts and results of this chapter are listed below:

- Strictly separating hyperplane.
- Farkas–Minkowski proposition.
- Farkas lemma, version I, Farkas lemma, version II.
- Distance of a point to a subset.
- Dual linear program, primal linear program.
- Dual variables, primal variables.
- Complementary slackness conditions.
- Dual simplex algorithm.
- Primal-dual algorithm.
- Restricted primal linear program.

47.8 Problems

Problem 47.1. Let (v_1, \dots, v_n) be a sequence of n vectors in \mathbb{R}^d and let V be the $d \times n$ matrix whose j -th column is v_j . Prove the equivalence of the following two statements:

- (a) There is no nontrivial positive linear dependence among the v_j , which means that there is no nonzero vector, $y = (y_1, \dots, y_n) \in \mathbb{R}^n$, with $y_j \geq 0$ for $j = 1, \dots, n$, so that

$$y_1 v_1 + \cdots + y_n v_n = 0$$

or equivalently, $Vy = 0$.

- (b) There is some vector, $c \in \mathbb{R}^d$, so that $c^\top V > 0$, which means that $c^\top v_j > 0$, for $j = 1, \dots, n$.

Problem 47.2. Check that the dual in maximization form (D'') of the Dual Program (D') (which is the dual of (P) in maximization form),

$$\begin{aligned} &\text{maximize} && -b^\top y^\top \\ &\text{subject to} && -A^\top y^\top \leq -c^\top \text{ and } y^\top \geq 0, \end{aligned}$$

where $y \in (\mathbb{R}^m)^*$, gives back the Primal Program (P).

Problem 47.3. In a General Linear Program (P) with n primal variables x_1, \dots, x_n and objective function $\sum_{j=1}^n c_j x_j$ (to be maximized), the m constraints are of the form

$$\begin{aligned} \sum_{j=1}^n a_{ij} x_j &\leq b_i, \\ \sum_{j=1}^n a_{ij} x_j &\geq b_i, \\ \sum_{j=1}^n a_{ij} x_j &= b_i, \end{aligned}$$

for $i = 1, \dots, m$, and the variables x_j satisfy an inequality of the form

$$\begin{aligned} x_j &\geq 0, \\ x_j &\leq 0, \\ x_j &\in \mathbb{R}, \end{aligned}$$

for $j = 1, \dots, n$. If y_1, \dots, y_m are the dual variables, show that the dual program of the linear program in standard form equivalent to (P) is equivalent to the linear program whose objective function is $\sum_{i=1}^m y_i b_i$ (to be minimized) and whose constraints are determined as follows:

$$\text{if } \begin{cases} x_j \geq 0 \\ x_j \leq 0 \\ x_j \in \mathbb{R} \end{cases}, \quad \text{then } \begin{cases} \sum_{i=1}^m a_{ij} y_i \geq c_j \\ \sum_{i=1}^m a_{ij} y_i \leq c_j \\ \sum_{i=1}^m a_{ij} y_i = c_j \end{cases},$$

and

$$\text{if } \begin{cases} \sum_{j=1}^n a_{ij}x_j \leq b_i \\ \sum_{j=1}^n a_{ij}x_j \geq b_i \\ \sum_{j=1}^n a_{ij}x_j = b_i \end{cases}, \quad \text{then } \begin{cases} y_i \geq 0 \\ y_i \leq 0 \\ y_i \in \mathbb{R} \end{cases}.$$

Problem 47.4. Apply the procedure of Problem 47.3 to show that the dual of the (general) linear program

$$\begin{aligned} & \text{maximize} && 3x_1 + 2x_2 + 5x_3 \\ & \text{subject to} && \\ & && 5x_1 + 3x_2 + x_3 = -8 \\ & && 4x_1 + 2x_2 + 8x_3 \leq 23 \\ & && 6x_1 + 7x_2 + 3x_3 \geq 1 \\ & && x_1 \leq 4, x_3 \geq 0 \end{aligned}$$

is the (general) linear program:

$$\begin{aligned} & \text{minimize} && -8y_1 + 23y_2 - y_3 + 4y_4 \\ & \text{subject to} && \\ & && 5y_1 + 4y_2 - 6y_3 + y_4 = 3 \\ & && 3y_1 + 2y_2 - 7y_3 = 2 \\ & && y_1 + 8y_2 - 3y_3 \geq 5 \\ & && y_2, y_3, y_4 \geq 0. \end{aligned}$$

Problem 47.5. (1) Prove that the dual of the (general) linear program

$$\begin{aligned} & \text{maximize} && cx \\ & \text{subject to} && Ax = b \text{ and } x \in \mathbb{R}^n \end{aligned}$$

is

$$\begin{aligned} & \text{minimize} && yb \\ & \text{subject to} && yA = c \text{ and } y \in \mathbb{R}^m. \end{aligned}$$

(2) Prove that the dual of the (general) linear program

$$\begin{aligned} & \text{maximize} && cx \\ & \text{subject to} && Ax \geq b \text{ and } x \geq 0 \end{aligned}$$

is

$$\begin{aligned} & \text{minimize} && yb \\ & \text{subject to} && yA \geq c \text{ and } y \leq 0. \end{aligned}$$

Problem 47.6. Use the complementary slackness conditions to confirm that

$$x_1 = 2, x_2 = 4, x_3 = 0, x_4 = 0, x_5 = 7, x_6 = 0$$

is an optimal solution of the following linear program (from Chavatal [40], Chapter 5):

$$\begin{aligned} & \text{maximize} && 18x_1 - 7x_2 + 12x_3 + 5x_4 + 8x_6 \\ & \text{subject to} && \end{aligned}$$

$$\begin{aligned} & 2x_1 - 6x_2 + 2x_3 + 7x_4 + 3x_5 + 8x_6 \leq 1 \\ & -3x_1 - x_2 + 4x_3 - 3x_4 + x_5 + 2x_6 \leq -2 \\ & 8x_1 - 3x_2 + 5x_3 - 2x_4 + 2x_6 \leq 4 \\ & 4x_1 + 8x_3 + 7x_4 - x_5 + 3x_6 \leq 1 \\ & 5x_1 + 2x_2 - 3x_3 + 6x_4 - 2x_5 - x_6 \leq 5 \\ & x_1, x_2, x_3, x_4, x_5, x_6 \geq 0. \end{aligned}$$

Problem 47.7. Check carefully that the dual simplex method is equivalent to the simplex method applied to the dual program in maximization form.

Part VIII

NonLinear Optimization

Chapter 48

Basics of Hilbert Spaces

Most of the “deep” results about the existence of minima of real-valued functions proven in Chapter 49 rely on two fundamental results of Hilbert space theory:

- (1) The projection lemma, which is a result about nonempty, closed, convex subsets of a Hilbert space V .
- (2) The Riesz representation theorem, which allows us to express a continuous linear form on a Hilbert space V in terms of a vector in V and the inner product on V .

The correctness of the Karush–Kuhn–Tucker conditions appearing in Lagrangian duality follows from a version of the Farkas–Minkowski proposition, which also follows from the projection lemma.

Thus, we feel that it is indispensable to review some basic results of Hilbert space theory, although in most applications considered here the Hilbert space in question will be finite-dimensional. However, in optimization theory, there are many problems where we seek to find a *function* minimizing some type of energy functional (often given by a bilinear form), in which case we are dealing with an infinite dimensional Hilbert space, so it necessary to develop tools to deal with the more general situation of infinite-dimensional Hilbert spaces.

48.1 The Projection Lemma

Given a Hermitian space $\langle E, \varphi \rangle$, we showed in Section 14.1 that the function $\| \cdot \|: E \rightarrow \mathbb{R}$ defined such that $\|u\| = \sqrt{\varphi(u, u)}$, is a norm on E . Thus, E is a normed vector space. If E is also complete, then it is a very interesting space.

Recall that completeness has to do with the convergence of Cauchy sequences. A normed vector space $\langle E, \| \cdot \| \rangle$ is automatically a metric space under the metric d defined such that $d(u, v) = \|v - u\|$ (see Chapter 37 for the definition of a normed vector space and of a metric space, or Lang [111, 112], or Dixmier [51]). Given a metric space E with metric d , a sequence

$(a_n)_{n \geq 1}$ of elements $a_n \in E$ is a *Cauchy sequence* iff for every $\epsilon > 0$, there is some $N \geq 1$ such that

$$d(a_m, a_n) < \epsilon \quad \text{for all } m, n \geq N.$$

We say that E is *complete* iff every Cauchy sequence converges to a limit (which is unique, since a metric space is Hausdorff).

Every finite dimensional vector space over \mathbb{R} or \mathbb{C} is complete. For example, one can show by induction that given any basis (e_1, \dots, e_n) of E , the linear map $h: \mathbb{C}^n \rightarrow E$ defined such that

$$h((z_1, \dots, z_n)) = z_1 e_1 + \cdots + z_n e_n$$

is a homeomorphism (using the *sup*-norm on \mathbb{C}^n). One can also use the fact that any two norms on a finite dimensional vector space over \mathbb{R} or \mathbb{C} are equivalent (see Chapter 9, or Lang [112], Dixmier [51], Schwartz [150]).

However, if E has infinite dimension, it may not be complete. When a Hermitian space is complete, a number of the properties that hold for finite dimensional Hermitian spaces also hold for infinite dimensional spaces. For example, any closed subspace has an orthogonal complement, and in particular, a finite dimensional subspace has an orthogonal complement. Hermitian spaces that are also complete play an important role in analysis. Since they were first studied by Hilbert, they are called Hilbert spaces.

Definition 48.1. A (complex) Hermitian space $\langle E, \varphi \rangle$ which is a complete normed vector space under the norm $\| \cdot \|$ induced by φ is called a *Hilbert space*. A real Euclidean space $\langle E, \varphi \rangle$ which is complete under the norm $\| \cdot \|$ induced by φ is called a *real Hilbert space*.

All the results in this section hold for complex Hilbert spaces as well as for real Hilbert spaces. We state all results for the complex case only, since they also apply to the real case, and since the proofs in the complex case need a little more care.

Example 48.1. The space ℓ^2 of all countably infinite sequences $x = (x_i)_{i \in \mathbb{N}}$ of complex numbers such that $\sum_{i=0}^{\infty} |x_i|^2 < \infty$ is a Hilbert space. It will be shown later that the map $\varphi: \ell^2 \times \ell^2 \rightarrow \mathbb{C}$ defined such that

$$\varphi((x_i)_{i \in \mathbb{N}}, (y_i)_{i \in \mathbb{N}}) = \sum_{i=0}^{\infty} x_i \overline{y_i}$$

is well defined, and that ℓ^2 is a Hilbert space under φ . In fact, we will prove a more general result (Proposition A.3).

Example 48.2. The set $C^\infty[a, b]$ of smooth functions $f: [a, b] \rightarrow \mathbb{C}$ is a Hermitian space under the Hermitian form

$$\langle f, g \rangle = \int_a^b f(x) \overline{g(x)} dx,$$

but it is not a Hilbert space because it is not complete. It is possible to construct its completion $L^2([a, b])$, which turns out to be the space of Lebesgue integrable functions on $[a, b]$.

Theorem 37.63 yields a quick proof of the fact that any Hermitian space E (with Hermitian product $\langle -, - \rangle$) can be embedded in a Hilbert space E_h .

Theorem 48.1. *Given a Hermitian space $(E, \langle -, - \rangle)$ (resp. Euclidean space), there is a Hilbert space $(E_h, \langle -, - \rangle_h)$ and a linear map $\varphi: E \rightarrow E_h$, such that*

$$\langle u, v \rangle = \langle \varphi(u), \varphi(v) \rangle_h$$

for all $u, v \in E$, and $\varphi(E)$ is dense in E_h . Furthermore, E_h is unique up to isomorphism.

Proof. Let $(\widehat{E}, \|\cdot\|_{\widehat{E}})$ be the Banach space, and let $\varphi: E \rightarrow \widehat{E}$ be the linear isometry, given by Theorem 37.63. Let $\|u\| = \sqrt{\langle u, u \rangle}$ (with $u \in E$) and $E_h = \widehat{E}$. If E is a real vector space, we know from Section refsec5bis that the inner product $\langle -, - \rangle$ can be expressed in terms of the norm $\|u\|$ by the polarity equation

$$\langle u, v \rangle = \frac{1}{2}(\|u + v\|^2 - \|u\|^2 - \|v\|^2),$$

and if E is a complex vector space, we know from Section 14.1 that we have the polarity equation

$$\langle u, v \rangle = \frac{1}{4}(\|u + v\|^2 - \|u - v\|^2 + i\|u + iv\|^2 - i\|u - iv\|^2).$$

By the Cauchy-Schwarz inequality, $|\langle u, v \rangle| \leq \|u\|\|v\|$, the map $\langle -, - \rangle: E \times E \rightarrow \mathbb{C}$ (resp. $\langle -, - \rangle: E \times E \rightarrow \mathbb{R}$) is continuous. However, it is not uniformly continuous, but we can get around this problem by using the polarity equations to extend it to a continuous map. By continuity, the polarity equations also hold in E_h , which shows that $\langle -, - \rangle$ extends to a positive definite Hermitian inner product (resp. Euclidean inner product) $\langle -, - \rangle_h$ on E_h induced by $\|\cdot\|_{\widehat{E}}$ extending $\langle -, - \rangle$. \square

Remark: We followed the approach in Schwartz [149] (Chapter XXIII, Section 42. Theorem 2). For other approaches, see Munkres [131] (Chapter 7, Section 43), and Bourbaki [27].

One of the most important facts about finite-dimensional Hermitian (and Euclidean) spaces is that they have orthonormal bases. This implies that, up to isomorphism, *every finite-dimensional Hermitian space is isomorphic to \mathbb{C}^n* (for some $n \in \mathbb{N}$) and that the inner product is given by

$$\langle (x_1, \dots, x_n), (y_1, \dots, y_n) \rangle = \sum_{i=1}^n x_i \overline{y_i}.$$

Furthermore, every subspace W has an orthogonal complement W^\perp , and the inner product induces a natural duality between E and E^* (actually, between \overline{E} and E^*) where E^* is the space of linear forms on E .

When E is a Hilbert space, E may be infinite dimensional, often of uncountable dimension. Thus, we can't expect that E always have an orthonormal basis. However, if we modify

the notion of basis so that a “Hilbert basis” is an orthogonal family that is also dense in E , i.e., every $v \in E$ is the limit of a sequence of finite combinations of vectors from the Hilbert basis, then we can recover most of the “nice” properties of finite-dimensional Hermitian spaces. For instance, if $(u_k)_{k \in K}$ is a Hilbert basis, for every $v \in E$, we can define the Fourier coefficients $c_k = \langle v, u_k \rangle / \|u_k\|$, and then, v is the “sum” of its Fourier series $\sum_{k \in K} c_k u_k$. However, the cardinality of the index set K can be very large, and it is necessary to define what it means for a family of vectors indexed by K to be summable. We will do this in Section A.1. It turns out that every Hilbert space is isomorphic to a space of the form $\ell^2(K)$, where $\ell^2(K)$ is a generalization of the space of Example 48.1 (see Theorem A.8, usually called the Riesz-Fischer theorem).

Our first goal is to prove that a closed subspace of a Hilbert space has an orthogonal complement. We also show that duality holds if we redefine the dual E' of E to be the space of *continuous* linear maps on E . Our presentation closely follows Bourbaki [27]. We also were inspired by Rudin [140], Lang [111, 112], Schwartz [150, 149], and Dixmier [51]. In fact, we highly recommend Dixmier [51] as a clear and simple text on the basics of topology and analysis. To achieve this goal, we must first prove the so-called projection lemma.

Recall that in a metric space E , a subset X of E is *closed* iff for every convergent sequence (x_n) of points $x_n \in X$, the limit $x = \lim_{n \rightarrow \infty} x_n$ also belongs to X . The *closure* \overline{X} of X is the set of all limits of convergent sequences (x_n) of points $x_n \in X$. Obviously, $X \subseteq \overline{X}$. We say that the subset X of E is *dense in E* iff $E = \overline{X}$, the closure of X , which means that every $a \in E$ is the limit of some sequence (x_n) of points $x_n \in X$. Convex sets will again play a crucial role. In a complex vector space E , a subset $C \subseteq E$ is convex if $(1 - \lambda)x + \lambda y \in C$ for all $x, y \in C$ and all *real* $\lambda \in [0, 1]$. Observe that a subspace is convex.

First we state the following easy “parallelogram law,” whose proof is left as an exercise.

Proposition 48.2. *If E is a Hermitian space, for any two vectors $u, v \in E$, we have*

$$\|u + v\|^2 + \|u - v\|^2 = 2(\|u\|^2 + \|v\|^2).$$

From the above, we get the following proposition:

Proposition 48.3. *If E is a Hermitian space, given any $d, \delta \in \mathbb{R}$ such that $0 \leq \delta < d$, let*

$$B = \{u \in E \mid \|u\| < d\} \quad \text{and} \quad C = \{u \in E \mid \|u\| \leq d + \delta\}.$$

For any convex set such A that $A \subseteq C - B$, we have

$$\|v - u\| \leq \sqrt{12d\delta},$$

for all $u, v \in A$ (see Figure 48.1).

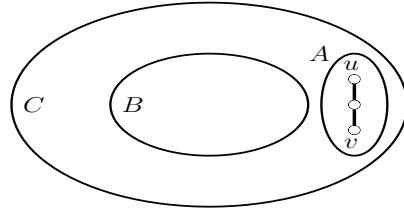

Figure 48.1: Inequality of Proposition 48.3.

Proof. Since A is convex, $\frac{1}{2}(u+v) \in A$ if $u, v \in A$, and thus, $\|\frac{1}{2}(u+v)\| \geq d$. From the parallelogram equality written in the form

$$\left\| \frac{1}{2}(u+v) \right\|^2 + \left\| \frac{1}{2}(u-v) \right\|^2 = \frac{1}{2} (\|u\|^2 + \|v\|^2),$$

since $\delta < d$, we get

$$\left\| \frac{1}{2}(u-v) \right\|^2 = \frac{1}{2} (\|u\|^2 + \|v\|^2) - \left\| \frac{1}{2}(u+v) \right\|^2 \leq (d+\delta)^2 - d^2 = 2d\delta + \delta^2 \leq 3d\delta,$$

from which

$$\|v-u\| \leq \sqrt{12d\delta}.$$

□

Definition 48.2. If X is a nonempty subset of a metric space (E, d) , for any $a \in E$, recall that we define the *distance* $d(a, X)$ of a to X as

$$d(a, X) = \inf_{b \in X} d(a, b).$$

Also, the *diameter* $\delta(X)$ of X is defined by

$$\delta(X) = \sup\{d(a, b) \mid a, b \in X\}.$$

It is possible that $\delta(X) = \infty$.

We leave the following standard two facts as an exercise (see Dixmier [51]):

Proposition 48.4. *Let E be a metric space.*

- (1) *For every subset $X \subseteq E$, $\delta(X) = \delta(\overline{X})$.*
- (2) *If E is a complete metric space, for every sequence (F_n) of closed nonempty subsets of E such that $F_{n+1} \subseteq F_n$, if $\lim_{n \rightarrow \infty} \delta(F_n) = 0$, then $\bigcap_{n=1}^{\infty} F_n$ consists of a single point.*

We are now ready to prove the crucial projection lemma.

Proposition 48.5. (*Projection lemma*) Let E be a Hilbert space and let $X \subseteq E$ be any nonempty convex and closed subset.

(1) For any $u \in E$, there is a unique vector $p_X(u) \in X$ such that

$$\|u - p_X(u)\| = \inf_{v \in X} \|u - v\| = d(u, X).$$

See Figure 48.2.

(2) The vector $p_X(u)$ is the unique vector $w \in E$ satisfying the following property (see Figure 48.3):

$$w \in X \quad \text{and} \quad \Re \langle u - w, z - w \rangle \leq 0 \quad \text{for all } z \in X. \quad (*)$$

(3) If X is a nonempty closed subspace of E , then the vector $p_X(u)$ is the unique vector $w \in E$ satisfying the following property:

$$w \in X \quad \text{and} \quad \langle u - w, z \rangle = 0 \quad \text{for all } z \in X. \quad (**)$$

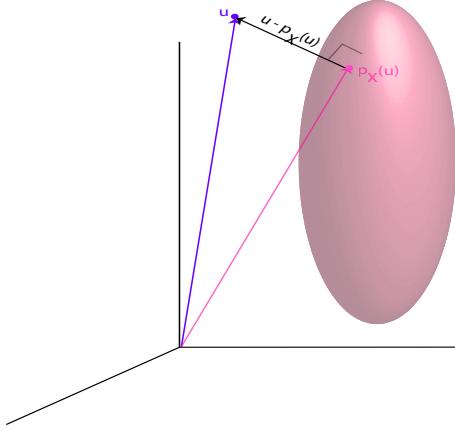

Figure 48.2: Let X be the solid pink ellipsoid. The projection of the purple point u onto X is the magenta point $p_X(u)$.

Proof. (1) Let $d = \inf_{v \in X} \|u - v\| = d(u, X)$. We define a sequence X_n of subsets of X as follows: for every $n \geq 1$,

$$X_n = \left\{ v \in X \mid \|u - v\| \leq d + \frac{1}{n} \right\}.$$

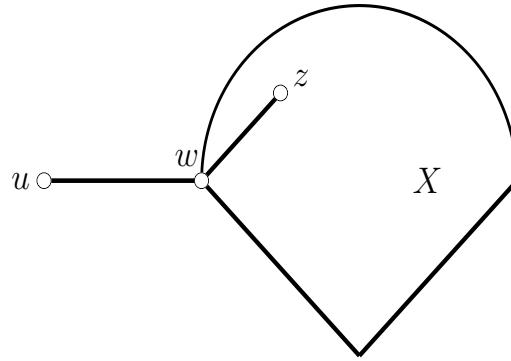

Figure 48.3: Inequality of Proposition 48.5.

It is immediately verified that each X_n is nonempty (by definition of d), convex, and that $X_{n+1} \subseteq X_n$. Also, by Proposition 48.3, (where $B = \{v \in E \mid \|u - v\| \leq d\}$, $C = \{v \in E \mid \|u - v\| \leq d + \frac{1}{n}\}$, and $A = X_n$), we have

$$\sup\{\|z - v\| \mid v, z \in X_n\} \leq \sqrt{12d/n},$$

and thus, $\bigcap_{n \geq 1} X_n$ contains at most one point; see Proposition 48.4(2). We will prove that $\bigcap_{n \geq 1} X_n$ contains exactly one point, namely, $p_X(u)$. For this, define a sequence $(w_n)_{n \geq 1}$ by picking some $w_n \in X_n$ for every $n \geq 1$. We claim that $(w_n)_{n \geq 1}$ is a Cauchy sequence. Given any $\epsilon > 0$, if we pick N such that

$$N > \frac{12d}{\epsilon^2},$$

since $(X_n)_{n \geq 1}$ is a monotonic decreasing sequence, which means that $X_{n+1} \subseteq X_n$ for all $n \geq 1$, for all $m, n \geq N$, we have

$$\|w_m - w_n\| \leq \sqrt{12d/N} < \epsilon,$$

as desired. Since E is complete, the sequence $(w_n)_{n \geq 1}$ has a limit w , and since $w_n \in X$ and X is closed, we must have $w \in X$. Also observe that

$$\|u - w\| \leq \|u - w_n\| + \|w_n - w\|,$$

and since w is the limit of $(w_n)_{n \geq 1}$ and

$$\|u - w_n\| \leq d + \frac{1}{n},$$

given any $\epsilon > 0$, there is some n large enough so that

$$\frac{1}{n} < \frac{\epsilon}{2} \quad \text{and} \quad \|w_n - w\| \leq \frac{\epsilon}{2},$$

and thus

$$\|u - w\| \leq d + \epsilon.$$

Since the above holds for every $\epsilon > 0$, we have $\|u - w\| = d$. Thus, $w \in X_n$ for all $n \geq 1$, which proves that $\bigcap_{n \geq 1} X_n = \{w\}$. Now any $z \in X$ such that $\|u - z\| = d(u, X) = d$ also belongs to every X_n , and thus $z = w$, proving the uniqueness of w , which we denote as $p_X(u)$. See Figure 48.4.

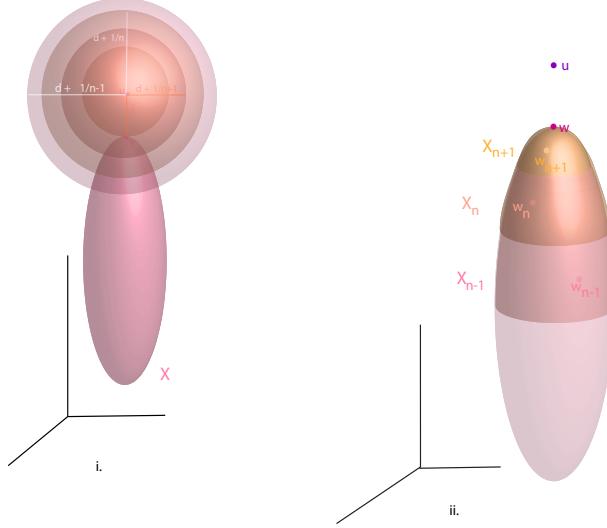

Figure 48.4: Let X be the solid pink ellipsoid with $p_X(u) = w$ at its apex. Each X_n is the intersection of X and a solid sphere centered at u with radius $d + 1/n$. These intersections are the colored “caps” of Figure ii. The Cauchy sequence $(w_n)_{n \geq 1}$ is obtained by selecting a point in each colored X_n .

(2) Let $z \in X$. Since X is convex, $v = (1 - \lambda)p_X(u) + \lambda z \in X$ for every λ , $0 \leq \lambda \leq 1$. Then by the definition of u , we have

$$\|u - v\| \geq \|u - p_X(u)\|$$

for all λ , $0 \leq \lambda \leq 1$, and since

$$\begin{aligned} \|u - v\|^2 &= \|u - p_X(u) - \lambda(z - p_X(u))\|^2 \\ &= \|u - p_X(u)\|^2 + \lambda^2 \|z - p_X(u)\|^2 - 2\lambda \Re \langle u - p_X(u), z - p_X(u) \rangle, \end{aligned}$$

for all λ , $0 < \lambda \leq 1$, we get

$$\Re \langle u - p_X(u), z - p_X(u) \rangle = \frac{1}{2\lambda} (\|u - p_X(u)\|^2 - \|u - v\|^2) + \frac{\lambda}{2} \|z - p_X(u)\|^2. \quad (\dagger)$$

Since

$$\|u - v\| \geq \|u - p_X(u)\|,$$

we have

$$\|u - p_X(u)\|^2 - \|u - v\|^2 = (\|u - p_X(u)\| - \|u - v\|)(\|u - p_X(u)\| + \|u - v\|) \leq 0,$$

and since Equation (\dagger) holds for all λ such that $0 < \lambda \leq 1$, if $\|u - p_X(u)\|^2 - \|u - v\|^2 < 0$, then for $\lambda > 0$ small enough we have

$$\frac{1}{2\lambda} (\|u - p_X(u)\|^2 - \|u - v\|^2) + \frac{\lambda}{2} \|z - p_X(u)\|^2 < 0,$$

and if $\|u - p_X(u)\|^2 - \|u - v\|^2 = 0$, then the limit of $\frac{\lambda}{2} \|z - p_X(u)\|^2$ as $\lambda > 0$ goes to zero is zero, so in all cases, by (\dagger), we have

$$\Re \langle u - p_X(u), z - p_X(u) \rangle \leq 0.$$

Conversely, assume that $w \in X$ satisfies the condition

$$\Re \langle u - w, z - w \rangle \leq 0$$

for all $z \in X$. For all $z \in X$, we have

$$\|u - z\|^2 = \|u - w\|^2 + \|z - w\|^2 - 2\Re \langle u - w, z - w \rangle \geq \|u - w\|^2,$$

which implies that $\|u - w\| = d(u, X) = d$, and from (1), that $w = p_X(u)$.

(3) If X is a subspace of E and $w \in X$, when z ranges over X the vector $z - w$ also ranges over the whole of X so Condition (*) is equivalent to

$$w \in X \quad \text{and} \quad \Re \langle u - w, z \rangle \leq 0 \quad \text{for all } z \in X. \quad (*_1)$$

Since X is a subspace, if $z \in X$, then $-z \in X$, which implies that $(*_1)$ is equivalent to

$$w \in X \quad \text{and} \quad \Re \langle u - w, z \rangle = 0 \quad \text{for all } z \in X. \quad (*_2)$$

Finally, since X is a subspace, if $z \in X$, then $iz \in X$, and this implies that

$$0 = \Re \langle u - w, iz \rangle = -i \Im \langle u - w, z \rangle,$$

so $\Im \langle u - w, z \rangle = 0$, but since we also have $\Re \langle u - w, z \rangle = 0$, we see that $(*_2)$ is equivalent to

$$w \in X \quad \text{and} \quad \langle u - w, z \rangle = 0 \quad \text{for all } z \in X, \quad (**)$$

as claimed. \square

Definition 48.3. The vector $p_X(u)$ is called the *projection of u onto X* , and the map $p_X: E \rightarrow X$ is called the *projection of E onto X* .

In the case of a real Hilbert space, there is an intuitive geometric interpretation of the condition

$$\langle u - p_X(u), z - p_X(u) \rangle \leq 0$$

for all $z \in X$. If we restate the condition as

$$\langle u - p_X(u), p_X(u) - z \rangle \geq 0$$

for all $z \in X$, this says that the absolute value of the measure of the angle between the vectors $u - p_X(u)$ and $p_X(u) - z$ is at most $\pi/2$. See Figure 48.5. This makes sense, since X is convex, and points in X must be on the side opposite to the “tangent space” to X at $p_X(u)$, which is orthogonal to $u - p_X(u)$. Of course, this is only an intuitive description, since the notion of tangent space has not been defined!

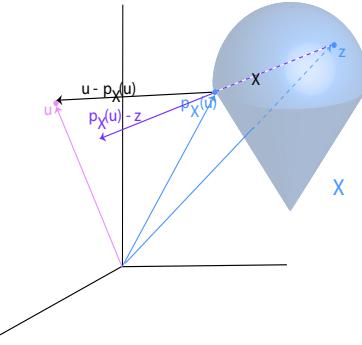

Figure 48.5: Let X be the solid blue ice cream cone. The acute angle between the black vector $u - p_X(u)$ and the purple vector $p_X(u) - z$ is less than $\pi/2$.

If X is a closed subspace of E , then Condition (**) says that the vector $u - p_X(u)$ is *orthogonal* to X , in the sense that $u - p_X(u)$ is orthogonal to every vector $z \in X$.

The map $p_X: E \rightarrow X$ is continuous as shown below.

Proposition 48.6. *Let E be a Hilbert space. For any nonempty convex and closed subset $X \subseteq E$, the map $p_X: E \rightarrow X$ is continuous. In fact, p_X satisfies the Lipschitz condition*

$$\|p_X(v) - p_X(u)\| \leq \|v - u\| \quad \text{for all } u, v \in E.$$

Proof. For any two vectors $u, v \in E$, let $x = p_X(u) - u$, $y = p_X(v) - p_X(u)$, and $z = v - p_X(v)$. Clearly, (as illustrated in Figure 48.6),

$$v - u = x + y + z,$$

and from Proposition 48.5(2), we also have

$$\Re \langle x, y \rangle \geq 0 \quad \text{and} \quad \Re \langle z, y \rangle \geq 0,$$

from which we get

$$\begin{aligned}\|v - u\|^2 &= \|x + y + z\|^2 = \|x + z + y\|^2 \\ &= \|x + z\|^2 + \|y\|^2 + 2\Re \langle x, y \rangle + 2\Re \langle z, y \rangle \\ &\geq \|y\|^2 = \|p_X(v) - p_X(u)\|^2.\end{aligned}$$

However, $\|p_X(v) - p_X(u)\| \leq \|v - u\|$ obviously implies that p_X is continuous. \square

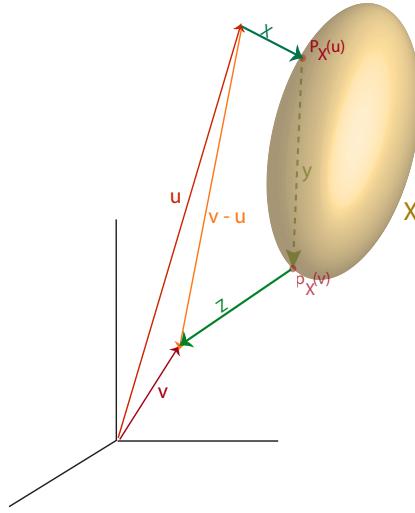

Figure 48.6: Let X be the solid gold ellipsoid. The vector $v - u$ is the sum of the three green vectors, each of which is determined by the appropriate projections.

We can now prove the following important proposition.

Proposition 48.7. *Let E be a Hilbert space.*

- (1) *For any closed subspace $V \subseteq E$, we have $E = V \oplus V^\perp$, and the map $p_V: E \rightarrow V$ is linear and continuous.*
- (2) *For any $u \in E$, the projection $p_V(u)$ is the unique vector $w \in E$ such that*

$$w \in V \quad \text{and} \quad \langle u - w, z \rangle = 0 \quad \text{for all } z \in V.$$

Proof. (1) First, we prove that $u - p_V(u) \in V^\perp$ for all $u \in E$. For any $v \in V$, since V is a subspace, $z = p_V(u) + \lambda v \in V$ for all $\lambda \in \mathbb{C}$, and since V is convex and nonempty (since it is a subspace), and closed by hypothesis, by Proposition 48.5(2), we have

$$\Re(\bar{\lambda} \langle u - p_V(u), v \rangle) = \Re(\langle u - p_V(u), \lambda v \rangle) = \Re \langle u - p_V(u), z - p_V(u) \rangle \leq 0$$

for all $\lambda \in \mathbb{C}$. In particular, the above holds for $\lambda = \langle u - p_V(u), v \rangle$, which yields

$$|\langle u - p_V(u), v \rangle| \leq 0,$$

and thus, $\langle u - p_V(u), v \rangle = 0$. See Figure 48.7. As a consequence, $u - p_V(u) \in V^\perp$ for all $u \in E$. Since $u = p_V(u) + u - p_V(u)$ for every $u \in E$, we have $E = V + V^\perp$. On the other hand, since $\langle -, - \rangle$ is positive definite, $V \cap V^\perp = \{0\}$, and thus $E = V \oplus V^\perp$.

We already proved in Proposition 48.6 that $p_V: E \rightarrow V$ is continuous. Also, since

$$p_V(\lambda u + \mu v) - (\lambda p_V(u) + \mu p_V(v)) = p_V(\lambda u + \mu v) - (\lambda u + \mu v) + \lambda(u - p_V(u)) + \mu(v - p_V(v)),$$

for all $u, v \in E$, and since the left-hand side term belongs to V , and from what we just showed, the right-hand side term belongs to V^\perp , we have

$$p_V(\lambda u + \mu v) - (\lambda p_V(u) + \mu p_V(v)) = 0,$$

showing that p_V is linear.

(2) This is basically obvious from (1). We proved in (1) that $u - p_V(u) \in V^\perp$, which is exactly the condition

$$\langle u - p_V(u), z \rangle = 0$$

for all $z \in V$. Conversely, if $w \in V$ satisfies the condition

$$\langle u - w, z \rangle = 0$$

for all $z \in V$, since $w \in V$, every vector $z \in V$ is of the form $y - w$, with $y = z + w \in V$, and thus, we have

$$\langle u - w, y - w \rangle = 0$$

for all $y \in V$, which implies the condition of Proposition 48.5(2):

$$\Re \langle u - w, y - w \rangle \leq 0$$

for all $y \in V$. By Proposition 48.5, $w = p_V(u)$ is the projection of u onto V . \square

Remark: If $p_V: E \rightarrow V$ is linear, then V is a subspace of E . It follows that if V is a closed convex subset of E , then $p_V: E \rightarrow V$ is linear iff V is a subspace of E .

Example 48.3. Let us illustrate the power of Proposition 48.7 on the following “least squares” problem. Given a real $m \times n$ -matrix A and some vector $b \in \mathbb{R}^m$, we would like to solve the linear system

$$Ax = b$$

in the least-squares sense, which means that we would like to find some solution $x \in \mathbb{R}^n$ that minimizes the Euclidean norm $\|Ax - b\|$ of the error $Ax - b$. It is actually not clear that the

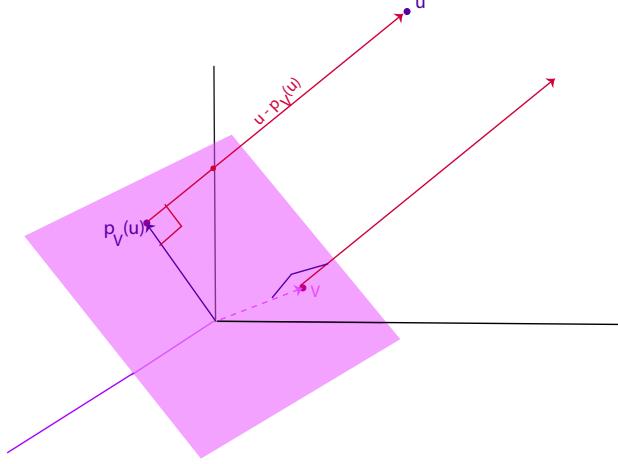

Figure 48.7: Let V be the pink plane. The vector $u - p_V(u)$ is perpendicular to any $v \in V$.

problem has a solution, but it does! The problem can be restated as follows: Is there some $x \in \mathbb{R}^n$ such that

$$\|Ax - b\| = \inf_{y \in \mathbb{R}^n} \|Ay - b\|,$$

or equivalently, is there some $z \in \text{Im}(A)$ such that

$$\|z - b\| = d(b, \text{Im}(A)),$$

where $\text{Im}(A) = \{Ay \in \mathbb{R}^m \mid y \in \mathbb{R}^n\}$, the image of the linear map induced by A . Since $\text{Im}(A)$ is a closed subspace of \mathbb{R}^m , because we are in finite dimension, Proposition 48.7 tells us that there is a unique $z \in \text{Im}(A)$ such that

$$\|z - b\| = \inf_{y \in \mathbb{R}^n} \|Ay - b\|,$$

and thus the problem always has a solution since $z \in \text{Im}(A)$, and since there is at least some $x \in \mathbb{R}^n$ such that $Ax = z$ (by definition of $\text{Im}(A)$). Note that such an x is not necessarily unique. Furthermore, Proposition 48.7 also tells us that $z \in \text{Im}(A)$ is the solution of the equation

$$\langle z - b, w \rangle = 0 \quad \text{for all } w \in \text{Im}(A),$$

or equivalently, that $x \in \mathbb{R}^n$ is the solution of

$$\langle Ax - b, Ay \rangle = 0 \quad \text{for all } y \in \mathbb{R}^n,$$

which is equivalent to

$$\langle A^\top(Ax - b), y \rangle = 0 \quad \text{for all } y \in \mathbb{R}^n,$$

and thus, since the inner product is positive definite, to $A^\top(Ax - b) = 0$, i.e.,

$$A^\top Ax = A^\top b.$$

Therefore, the solutions of the original least-squares problem are precisely the solutions of the so-called *normal equations*

$$A^\top Ax = A^\top b,$$

discovered by Gauss and Legendre around 1800. We also proved that the normal equations always have a solution.

Computationally, it is best not to solve the normal equations directly, and instead, to use methods such as the *QR*-decomposition (applied to A) or the SVD-decomposition (in the form of the pseudo-inverse). We will come back to this point later on.

Here is another important corollary of Proposition 48.7.

Corollary 48.8. *For any continuous nonnull linear map $h: E \rightarrow \mathbb{C}$, the null space*

$$H = \text{Ker } h = \{u \in E \mid h(u) = 0\} = h^{-1}(0)$$

is a closed hyperplane H , and thus, H^\perp is a subspace of dimension one such that $E = H \oplus H^\perp$.

The above suggests defining the dual space of E as the set of all continuous maps $h: E \rightarrow \mathbb{C}$.

Remark: If $h: E \rightarrow \mathbb{C}$ is a linear map which is **not** continuous, then it can be shown that the hyperplane $H = \text{Ker } h$ is dense in E ! Thus, H^\perp is reduced to the trivial subspace $\{0\}$. This goes against our intuition of what a hyperplane in \mathbb{R}^n (or \mathbb{C}^n) is, and warns us not to trust our “physical” intuition too much when dealing with infinite dimensions. As a consequence, the map $\flat: E \rightarrow E^*$ introduced in Section 14.2 (see just after Definition 48.4 below) is not surjective, since the linear forms of the form $u \mapsto \langle u, v \rangle$ (for some fixed vector $v \in E$) are continuous (the inner product is continuous).

48.2 Duality and the Riesz Representation Theorem

We now show that by redefining the dual space of a Hilbert space as the set of continuous linear forms on E we recover Theorem 14.6.

Definition 48.4. Given a Hilbert space E , we define the *dual space E' of E* as the vector space of all continuous linear forms $h: E \rightarrow \mathbb{C}$. Maps in E' are also called *bounded linear operators*, *bounded linear functionals*, or simply *operators* or *functionals*.

As in Section 14.2, for all $u, v \in E$, we define the maps $\varphi_u^l: E \rightarrow \mathbb{C}$ and $\varphi_v^r: E \rightarrow \mathbb{C}$ such that

$$\varphi_u^l(v) = \overline{\langle u, v \rangle},$$

and

$$\varphi_v^r(u) = \langle u, v \rangle.$$

In fact, $\varphi_u^l = \varphi_u^r$, and because the inner product $\langle -, - \rangle$ is continuous, it is obvious that φ_v^r is continuous and linear, so that $\varphi_v^r \in E'$. To simplify notation, we write φ_v instead of φ_v^r .

Theorem 14.6 is generalized to Hilbert spaces as follows.

Proposition 48.9. (*Riesz representation theorem*) *Let E be a Hilbert space. Then the map $\flat: E \rightarrow E'$ defined such that*

$$\flat(v) = \varphi_v,$$

is semilinear, continuous, and bijective. Furthermore, for any continuous linear map $\psi \in E'$, if $u \in E$ is the unique vector such that

$$\psi(v) = \langle v, u \rangle \quad \text{for all } v \in E,$$

then we have $\|\psi\| = \|u\|$, where

$$\|\psi\| = \sup \left\{ \frac{|\psi(v)|}{\|v\|} \mid v \in E, v \neq 0 \right\}.$$

Proof. The proof is basically identical to the proof of Theorem 14.6, except that a different argument is required for the surjectivity of $\flat: E \rightarrow E'$, since E may not be finite dimensional. For any nonnull linear operator $h \in E'$, the hyperplane $H = \text{Ker } h = h^{-1}(0)$ is a closed subspace of E , and by Proposition 48.7, H^\perp is a subspace of dimension one such that $E = H \oplus H^\perp$. Then picking any nonnull vector $w \in H^\perp$, observe that H is also the kernel of the linear operator φ_w , with

$$\varphi_w(u) = \langle u, w \rangle,$$

and thus, since any two nonzero linear forms defining the same hyperplane must be proportional, there is some nonzero scalar $\lambda \in \mathbb{C}$ such that $h = \lambda \varphi_w$. But then, $h = \varphi_{\bar{\lambda}w}$, proving that $\flat: E \rightarrow E'$ is surjective.

By the Cauchy–Schwarz inequality we have

$$|\psi(v)| = |\langle v, u \rangle| \leq \|v\| \|u\|,$$

so by definition of $\|\psi\|$ we get

$$\|\psi\| \leq \|u\|.$$

Obviously $\psi = 0$ iff $u = 0$ so assume $u \neq 0$. We have

$$\|u\|^2 = \langle u, u \rangle = \psi(u) \leq \|\psi\| \|u\|,$$

which yields $\|u\| \leq \|\psi\|$, and therefore $\|\psi\| = \|u\|$, as claimed. \square

Proposition 48.9 is known as the *Riesz representation theorem* or “*Little Riesz Theorem*.” It shows that the inner product on a Hilbert space induces a natural semilinear isomorphism between E and its dual E' (equivalently, a linear isomorphism between \overline{E} and E'). This isomorphism is an isometry (it is preserves the norm).

Remark: Many books on quantum mechanics use the so-called Dirac notation to denote objects in the Hilbert space E and operators in its dual space E' . In the Dirac notation, an element of E is denoted as $|x\rangle$, and an element of E' is denoted as $\langle t|$. The scalar product is denoted as $\langle t| \cdot |x\rangle$. This uses the isomorphism between E and E' , except that the inner product is assumed to be semi-linear on the left rather than on the right.

Proposition 48.9 allows us to define the adjoint of a linear map, as in the Hermitian case (see Proposition 14.8). Actually, we can prove a slightly more general result which is used in optimization theory.

If $\varphi: E \times E \rightarrow \mathbb{C}$ is a sesquilinear map on a normed vector space $(E, \| \cdot \|)$, then Proposition 37.59 is immediately adapted to prove that φ is continuous iff there is some constant $k \geq 0$ such that

$$|\varphi(u, v)| \leq k \|u\| \|v\| \quad \text{for all } u, v \in E.$$

Thus we define $\|\varphi\|$ as in Definition 37.42 by

$$\|\varphi\| = \sup \{ |\varphi(x, y)| \mid \|x\| \leq 1, \|y\| \leq 1, x, y \in E \}.$$

Proposition 48.10. *Given a Hilbert space E , for every continuous sesquilinear map $\varphi: E \times E \rightarrow \mathbb{C}$, there is a unique continuous linear map $f_\varphi: E \rightarrow E$, such that*

$$\varphi(u, v) = \langle u, f_\varphi(v) \rangle \quad \text{for all } u, v \in E.$$

We also have $\|f_\varphi\| = \|\varphi\|$. If φ is Hermitian, then f_φ is self-adjoint, that is

$$\langle u, f_\varphi(v) \rangle = \langle f_\varphi(u), v \rangle \quad \text{for all } u, v \in E.$$

Proof. The proof is adapted from Rudin [141] (Theorem 12.8). To define the function f_φ , we proceed as follows. For any fixed $v \in E$, define the linear map φ_v by

$$\varphi_v(u) = \varphi(u, v) \quad \text{for all } u \in E.$$

Since φ is continuous, φ_v is continuous. So by Proposition 48.9, there is a unique vector in E that we denote $f_\varphi(v)$ such that

$$\varphi_v(u) = \langle u, f_\varphi(v) \rangle \quad \text{for all } u \in E,$$

and $\|f_\varphi(v)\| = \|\varphi_v\|$. Let us check that the map $v \mapsto f_\varphi(v)$ is linear.

We have

$$\begin{aligned} \varphi(u, v_1 + v_2) &= \varphi(u, v_1) + \varphi(u, v_2) && \varphi \text{ is additive} \\ &= \langle u, f_\varphi(v_1) \rangle + \langle u, f_\varphi(v_2) \rangle && \text{by definition of } f_\varphi \\ &= \langle u, f_\varphi(v_1) + f_\varphi(v_2) \rangle && \langle -, - \rangle \text{ is additive} \end{aligned}$$

for all $u \in E$, and since $f_\varphi(v_1+v_2)$ is the unique vector such that $\varphi(u, v_1+v_2) = \langle u, f_\varphi(v_1+v_2) \rangle$ for all $u \in E$, we must have

$$f_\varphi(v_1 + v_2) = f_\varphi(v_1) + f_\varphi(v_2).$$

For any $\lambda \in \mathbb{C}$ we have

$$\begin{aligned} \varphi(u, \lambda v) &= \bar{\lambda} \varphi(u, v) && \varphi \text{ is sesquilinear} \\ &= \bar{\lambda} \langle u, f_\varphi(v) \rangle && \text{by definition of } f_\varphi \\ &= \langle u, \lambda f_\varphi(v) \rangle && \langle -, - \rangle \text{ is sesquilinear} \end{aligned}$$

for all $u \in E$, and since $f_\varphi(\lambda v)$ is the unique vector such that $\varphi(u, \lambda v) = \langle u, f_\varphi(\lambda v) \rangle$ for all $u \in E$, we must have

$$f_\varphi(\lambda v) = \lambda f_\varphi(v).$$

Therefore f_φ is linear.

Then by definition of $\|\varphi\|$, we have

$$|\varphi_v(u)| = |\varphi(u, v)| \leq \|\varphi\| \|u\| \|v\|,$$

which shows that $\|\varphi_v\| \leq \|\varphi\| \|v\|$. Since $\|f_\varphi(v)\| = \|\varphi_v\|$, we have

$$\|f_\varphi(v)\| \leq \|\varphi\| \|v\|,$$

which shows that f_φ is continuous and that $\|f_\varphi\| \leq \|\varphi\|$. But by the Cauchy–Schwarz inequality we also have

$$|\varphi(u, v)| = |\langle u, f_\varphi(v) \rangle| \leq \|u\| \|f_\varphi(v)\| \leq \|u\| \|f_\varphi\| \|v\|,$$

so $\|\varphi\| \leq \|f_\varphi\|$, and thus

$$\|f_\varphi\| = \|\varphi\|.$$

If φ is Hermitian, $\varphi(v, u) = \overline{\varphi(u, v)}$, so

$$\langle f_\varphi(u), v \rangle = \overline{\langle v, f_\varphi(u) \rangle} = \overline{\varphi(v, u)} = \varphi(u, v) = \langle u, f_\varphi(v) \rangle,$$

which shows that f_φ is self-adjoint. \square

Proposition 48.11. *Given a Hilbert space E , for every continuous linear map $f: E \rightarrow E$, there is a unique continuous linear map $f^*: E \rightarrow E$, such that*

$$\langle f(u), v \rangle = \langle u, f^*(v) \rangle \quad \text{for all } u, v \in E,$$

and we have $\|f^*\| = \|f\|$. The map f^* is called the adjoint of f .

Proof. The proof is adapted from Rudin [141] (Section 12.9). By the Cauchy–Schwarz inequality, since

$$|\langle x, y \rangle| \leq \|x\| \|y\|,$$

we see that the sesquilinear map $(x, y) \mapsto \langle x, y \rangle$ on $E \times E$ is continuous. Let $\varphi: E \times E \rightarrow \mathbb{C}$ be the sesquilinear map given by

$$\varphi(u, v) = \langle f(u), v \rangle \quad \text{for all } u, v \in E.$$

Since f is continuous and the inner product $\langle -, - \rangle$ is continuous, this is a continuous map. By Proposition 48.10, there is a unique linear map $f^*: E \rightarrow E$ such that

$$\langle f(u), v \rangle = \varphi(u, v) = \langle u, f^*(v) \rangle \quad \text{for all } u, v \in E,$$

with $\|f^*\| = \|\varphi\|$.

We can also prove that $\|\varphi\| = \|f\|$. First, by definition of $\|\varphi\|$ we have

$$\begin{aligned} \|\varphi\| &= \sup \{ |\varphi(x, y)| \mid \|x\| \leq 1, \|y\| \leq 1 \} \\ &= \sup \{ |\langle f(x), y \rangle| \mid \|x\| \leq 1, \|y\| \leq 1 \} \\ &\leq \sup \{ \|f(x)\| \|y\| \mid \|x\| \leq 1, \|y\| \leq 1 \} \\ &\leq \sup \{ \|f(x)\| \mid \|x\| \leq 1 \} \\ &= \|f\|. \end{aligned}$$

In the other direction we have

$$\|f(x)\|^2 = \langle f(x), f(x) \rangle = \varphi(x, f(x)) \leq \|\varphi\| \|x\| \|f(x)\|,$$

and if $f(x) \neq 0$ we get $\|f(x)\| \leq \|\varphi\| \|x\|$. This inequality holds trivially if $f(x) = 0$, so we conclude that $\|f\| \leq \|\varphi\|$. Therefore we have

$$\|\varphi\| = \|f\|,$$

as claimed, and consequently $\|f^*\| = \|\varphi\| = \|f\|$. □

It is easy to show that the adjoint satisfies the following properties:

$$\begin{aligned} (f + g)^* &= f^* + g^* \\ (\lambda f)^* &= \bar{\lambda} f^* \\ (f \circ g)^* &= g^* \circ f^* \\ f^{**} &= f. \end{aligned}$$

One can also show that $\|f^* \circ f\| = \|f\|^2$ (see Rudin [141], Section 12.9).

As in the Hermitian case, given two Hilbert spaces E and F , the above results can be adapted to show that for any linear map $f: E \rightarrow F$, there is a unique linear map $f^*: F \rightarrow E$ such that

$$\langle f(u), v \rangle_2 = \langle u, f^*(v) \rangle_1$$

for all $u \in E$ and all $v \in F$. The linear map f^* is also called the adjoint of f .

48.3 Farkas–Minkowski Lemma in Hilbert Spaces

In this section $(V, \langle -, - \rangle)$ is assumed to be a *real* Hilbert space. The projection lemma can be used to show an interesting version of the Farkas–Minkowski lemma in a Hilbert space.

Given a finite sequence of vectors (a_1, \dots, a_m) with $a_i \in V$, let C be the polyhedral cone

$$C = \text{cone}(a_1, \dots, a_m) = \left\{ \sum_{i=1}^m \lambda_i a_i \mid \lambda_i \geq 0, i = 1, \dots, m \right\}.$$

For any vector $b \in V$, the Farkas–Minkowski lemma gives a criterion for checking whether $b \in C$.

In Proposition 44.2 we proved that every polyhedral cone $\text{cone}(a_1, \dots, a_m)$ with $a_i \in \mathbb{R}^n$ is closed. Close examination of the proof shows that it goes through if $a_i \in V$ where V is any vector space possibly of infinite dimension, because the important fact is that the number m of these vectors is finite, not their dimension.

Theorem 48.12. (*Farkas–Minkowski Lemma in Hilbert Spaces*) *Let $(V, \langle -, - \rangle)$ be a real Hilbert space. For any finite sequence of vectors (a_1, \dots, a_m) with $a_i \in V$, if C is the polyhedral cone $C = \text{cone}(a_1, \dots, a_m)$, for any vector $b \in V$, we have $b \notin C$ iff there is a vector $u \in V$ such that*

$$\langle a_i, u \rangle \geq 0 \quad i = 1, \dots, m, \quad \text{and} \quad \langle b, u \rangle < 0.$$

Equivalently, $b \in C$ iff for all $u \in V$,

$$\text{if } \langle a_i, u \rangle \geq 0 \quad i = 1, \dots, m, \quad \text{then} \quad \langle b, u \rangle \geq 0.$$

Proof. We follow Ciarlet [41] (Chapter 9, Theorem 9.1.1). We already established in Proposition 44.2 that the polyhedral cone $C = \text{cone}(a_1, \dots, a_m)$ is closed. Next we claim the following:

Claim: If C is a nonempty, closed, convex subset of a Hilbert space V , and $b \in V$ is any vector such that $b \notin C$, then there exist some $u \in V$ and infinitely many scalars $\alpha \in \mathbb{R}$ such that

$$\begin{aligned} \langle v, u \rangle &> \alpha \quad \text{for every } v \in C \\ \langle b, u \rangle &< \alpha. \end{aligned}$$

We use the projection lemma (Proposition 48.5) which says that since $b \notin C$ there is some unique $c = p_C(b) \in C$ such that

$$\begin{aligned} \|b - c\| &= \inf_{v \in C} \|b - v\| > 0 \\ \langle b - c, v - c \rangle &\leq 0 \quad \text{for all } v \in C, \end{aligned}$$

or equivalently

$$\begin{aligned}\|b - c\| &= \inf_{v \in C} \|b - v\| > 0 \\ \langle v - c, c - b \rangle &\geq 0 \quad \text{for all } v \in C.\end{aligned}$$

As a consequence, since $b \notin C$ and $c \in C$, we have $c - b \neq 0$, so

$$\langle v, c - b \rangle \geq \langle c, c - b \rangle > \langle b, c - b \rangle$$

because $\langle c, c - b \rangle - \langle b, c - b \rangle = \langle c - b, c - b \rangle > 0$, and if we pick $u = c - b$ and any α such that

$$\langle c, c - b \rangle > \alpha > \langle b, c - b \rangle,$$

the claim is satisfied.

We now prove the Farkas–Minkowski lemma. Assume that $b \notin C$. Since C is nonempty, convex, and closed, by the claim there is some $u \in V$ and some $\alpha \in \mathbb{R}$ such that

$$\begin{aligned}\langle v, u \rangle &> \alpha \quad \text{for every } v \in C \\ \langle b, u \rangle &< \alpha.\end{aligned}$$

But C is a polyhedral cone containing 0, so we must have $\alpha < 0$. Then for every $v \in C$, since C a polyhedral cone if $v \in C$ then $\lambda v \in C$ for all $\lambda > 0$, so by the above

$$\langle v, u \rangle > \frac{\alpha}{\lambda} \quad \text{for every } \lambda > 0,$$

which implies that

$$\langle v, u \rangle \geq 0.$$

Since $a_i \in C$ for $i = 1, \dots, m$, we proved that

$$\langle a_i, u \rangle \geq 0 \quad i = 1, \dots, m \quad \text{and} \quad \langle b, u \rangle < \alpha < 0,$$

which proves Farkas lemma. □

Remark: Observe that the claim established during the proof of Theorem 48.12 shows that the affine hyperplane $H_{u,\alpha}$ of equation $\langle v, u \rangle = \alpha$ for all $v \in V$ separates strictly C and $\{b\}$.

48.4 Summary

The main concepts and results of this chapter are listed below:

- Hilbert space.
- Projection lemma.

- Distance of a point to a subset, diameter.
- Projection onto a closed and convex subset.
- Orthogonal complement of a closed subspace.
- Dual of a Hilbert space.
- Bounded linear operator (or functional).
- Riesz representation theorem.
- Adjoint of a continuous linear map.
- Farkas–Minkowski lemma.

48.5 Problems

Problem 48.1. Let V be a Hilbert space. Prove that a subspace W of V is dense in V if and only if there is no nonzero vector orthogonal to W .

Problem 48.2. Prove that the adjoint satisfies the following properties:

$$\begin{aligned}(f + g)^* &= f^* + g^* \\ (\lambda f)^* &= \bar{\lambda} f^* \\ (f \circ g)^* &= g^* \circ f^* \\ f^{**} &= f.\end{aligned}$$

Problem 48.3. Prove that $\|f^* \circ f\| = \|f\|^2$.

Problem 48.4. Let V be a (real) Hilbert space and let C be a nonempty closed convex subset of V . Define the map $h: V \rightarrow \mathbb{R} \cup \{+\infty\}$ by

$$h(u) = \sup_{v \in C} \langle u, v \rangle.$$

Prove that

$$C = \bigcap_{u \in V} \{v \in V \mid \langle u, v \rangle \leq h(u)\} = \bigcap_{u \in \Lambda_C} \{v \in V \mid \langle u, v \rangle \leq h(u)\},$$

where $\Lambda_C = \{u \in V \mid h(u) \neq +\infty\}$.

Describe Λ_C when C is also a subspace of V .

Problem 48.5. Let A be a real $m \times n$ matrix, and let (u_k) be a sequence of vectors $u_k \in \mathbb{R}^n$ such that $u_k \geq 0$. Prove that if the sequence (Au_k) converges, then there is some $u \in \mathbb{R}^n$ such that

$$Au = \lim_{k \rightarrow \infty} Au_k \quad \text{and} \quad u \geq 0.$$

Problem 48.6. Let V be a real Hilbert space, (a_1, \dots, a_m) a sequence of m vectors in V , b some vector in V , $(\alpha_1, \dots, \alpha_m)$ a sequence of m real numbers, and β some real number. Prove that the inclusion

$$\{w \in V \mid \langle a_i, w \rangle \geq \alpha_i, 1 \leq i \leq m\} \subseteq \{w \in V \mid \langle b, w \rangle \geq \beta\}$$

holds if and only if there exist $\lambda_1, \dots, \lambda_m \in \mathbb{R}$ such that $\lambda_i \geq 0$ for $i = 1, \dots, m$ and

$$\begin{aligned} b &= \sum_{i=1}^m \lambda_i a_i \\ \beta &\leq \sum_{i=1}^m \lambda_i \alpha_i. \end{aligned}$$

Chapter 49

General Results of Optimization Theory

This chapter is devoted to some general results of optimization theory. A main theme is to find sufficient conditions that ensure that an objective function has a minimum which is achieved. We define the notion of a coercive function. The most general result is Theorem 49.2, which applies to a coercive convex function on a convex subset of a separable Hilbert space. In the special case of a coercive quadratic functional, we obtain the Lions–Stampacchia theorem (Theorem 49.6), and the Lax–Milgram theorem (Theorem 49.7). We define elliptic functionals, which generalize quadratic functions defined by symmetric positive definite matrices. We define gradient descent methods, and discuss their convergence. A gradient descent method looks for a descent direction and a stepsize parameter, which is obtained either using an exact line search or a backtracking line search. A popular technique to find the search direction is steepest descent. In addition to steepest descent for the Euclidean norm, we discuss steepest descent for an arbitrary norm. We also consider a special case of steepest descent, Newton’s method. This method converges faster than the other gradient descent methods, but it is quite expensive since it requires computing and storing Hessians. We also present the method of conjugate gradients and prove its correctness. We briefly discuss the method of gradient projection and the penalty method in the case of constrained optima.

49.1 Optimization Problems; Basic Terminology

The main goal of *optimization theory* is to construct *algorithms* to find solutions (often approximate) of problems of the form

$$\begin{aligned} &\text{find } u \\ &\text{such that } u \in U \text{ and } J(u) = \inf_{v \in U} J(v), \end{aligned}$$

where U is a given subset of a (real) vector space V (possibly infinite dimensional) and $J: \Omega \rightarrow \mathbb{R}$ is a function defined on some open subset Ω of V such that $U \subseteq \Omega$.

To be very clear, $\inf_{v \in U} J(v)$ denotes the *greatest lower bound* of the set of real numbers $\{J(u) \mid u \in U\}$. To make sure that we are on firm grounds, let us review the notions of greatest lower bound and least upper bound of a set of real numbers.

Let X be any nonempty subset of \mathbb{R} . The set $LB(X)$ of *lower bounds* of X is defined as

$$LB(X) = \{b \in \mathbb{R} \mid b \leq x \text{ for all } x \in X\}.$$

If the set X is not bounded below, which means that for every $r \in \mathbb{R}$ there is some $x \in X$ such that $x < r$, then $LB(X)$ is empty. Otherwise, if $LB(X)$ is nonempty, since it is bounded above by every element of X , by a fundamental property of the real numbers, the set $LB(X)$ has a greatest element denoted $\inf X$. The real number $\inf X$ is thus the *greatest lower bound* of X . In general, $\inf X$ does not belong to X , but if it does, then it is the least element of X .

If $LB(X) = \emptyset$, then X is *unbounded below* and $\inf X$ is undefined. In this case (with an abuse of notation), we write

$$\inf X = -\infty.$$

By convention, when $X = \emptyset$ we set

$$\inf \emptyset = +\infty.$$

For example, if $X = \{x \in \mathbb{R} \mid x \leq 0\}$, then $LB(X) = \emptyset$. On the other hand, if $X = \{1/n \mid n \in \mathbb{N} - \{0\}\}$, then $LB(X) = \{x \in \mathbb{R} \mid x \leq 0\}$ and $\inf X = 0$, which is not in X .

Similarly, the set $UB(X)$ of *upper bounds* of X is given by

$$UB(X) = \{u \in \mathbb{R} \mid x \leq u \text{ for all } x \in X\}.$$

If X is not bounded above, then $UB(X) = \emptyset$. Otherwise, if $UB(X) \neq \emptyset$, then it has least element denoted $\sup X$. Thus $\sup X$ is the *least upper bound* of X . If $\sup X \in X$, then it is the greatest element of X . If $UB(X) = \emptyset$, then

$$\sup X = +\infty.$$

By convention, when $X = \emptyset$ we set

$$\sup \emptyset = -\infty.$$

For example, if $X = \{x \in \mathbb{R} \mid x \geq 0\}$, then $UB(X) = \emptyset$. On the other hand, if $X = \{1 - 1/n \mid n \in \mathbb{N} - \{0\}\}$, then $UB(X) = \{x \in \mathbb{R} \mid x \geq 1\}$ and $\sup X = 1$, which is not in X .

The element $\inf_{v \in U} J(v)$ is just $\inf\{J(v) \mid v \in U\}$. The notation J^* is often used to denote $\inf_{v \in U} J(v)$. If the function J is not bounded below, which means that for every $r \in \mathbb{R}$, there is some $u \in U$ such that $J(u) < r$, then

$$\inf_{v \in U} J(v) = -\infty,$$

and we say that our minimization problem has no solution, or that it is unbounded (below). For example, if $V = \Omega = \mathbb{R}$, $U = \{x \in \mathbb{R} \mid x \leq 0\}$, and $J(x) = x$, then the function $J(x)$ is not bounded below and $\inf_{v \in U} J(v) = -\infty$.

The issue is that J^* may not belong to $\{J(u) \mid u \in U\}$, that is, it may not be achieved by some element $u \in U$, and solving the above problem consists in finding some $u \in U$ that achieves the value J^* in the sense that $J(u) = J^*$. If no such $u \in U$ exists, again we say that our minimization problem has no solution.

The minimization problem

$$\begin{aligned} &\text{find } u \\ &\text{such that } u \in U \text{ and } J(u) = \inf_{v \in U} J(v) \end{aligned}$$

is often presented in the following more informal way:

$$\begin{aligned} &\text{minimize } J(v) \\ &\text{subject to } v \in U. \end{aligned} \tag{Problem M}$$

A vector $u \in U$ such that $J(u) = \inf_{v \in U} J(v)$ is often called a *minimizer* of J over U . Some authors denote the set of minimizers of J over U by $\arg \min_{v \in U} J(v)$ and write

$$u \in \arg \min_{v \in U} J(v)$$

to express that u is such a minimizer. When such a minimizer is unique, by abuse of notation, this unique minimizer u is denoted by

$$u = \arg \min_{v \in U} J(v).$$

We prefer not to use this notation, although it seems to have invaded the literature.

If we need to maximize rather than minimize a function, then we try to find some $u \in U$ such that

$$J(u) = \sup_{v \in U} J(v).$$

Here $\sup_{v \in U} J(v)$ is the least upper bound of the set $\{J(u) \mid u \in U\}$. Some authors denote the set of *maximizers* of J over U by $\arg \max_{v \in U} J(v)$.

Remark: Some authors define an *extended real-valued function* as a function $f: \Omega \rightarrow \mathbb{R}$ which is allowed to take the value $-\infty$ or even $+\infty$ for some of its arguments. Although this may be convenient to deal with situations where we need to consider $\inf_{v \in U} J(v)$ or $\sup_{v \in U} J(v)$, such “functions” are really partial functions and we prefer not to use the notion of extended real-valued function.

In most cases, U is defined as the set of solutions of a finite sets of *constraints*, either equality constraints $\varphi_i(v) = 0$, or inequality constraints $\varphi_i(v) \leq 0$, where the $\varphi_i: \Omega \rightarrow \mathbb{R}$ are some given functions. The function J is often called the *functional* of the optimization problem. This is a slightly odd terminology, but it is justified if V is a function space.

The following questions arise naturally:

- (1) Results concerning the *existence and uniqueness* of a solution for Problem (M). In the next section we state sufficient conditions either on the domain U or on the function J that ensure the existence of a solution.
- (2) The *characterization* of the possible solutions of Problem M. These are conditions for any element $u \in U$ to be a solution of the problem. Such conditions usually involve the derivative dJ_u of J , and possibly the derivatives of the functions φ_i defining U . Some of these conditions become sufficient when the functions φ_i are convex,
- (3) The effective construction of *algorithms*, typically iterative algorithms that construct a sequence $(u_k)_{k \geq 1}$ of elements of U whose limit is a solution $u \in U$ of our problem. It is then necessary to understand when and how quickly such sequences converge. Gradient descent methods fall under this category. As a general rule, unconstrained problems (for which $U = \Omega = V$) are (much) easier to deal with than constrained problems (where $U \neq V$).

The material of this chapter is heavily inspired by Ciarlet [41]. *In this chapter it is assumed that V is a real vector space with an inner product $\langle -, - \rangle$.* If V is infinite dimensional, then we assume that it is a real Hilbert space (it is complete). As usual, we write $\|u\| = \langle u, u \rangle^{1/2}$ for the norm associated with the inner product $\langle -, - \rangle$. The reader may want to review Section 48.1, especially the projection lemma and the Riesz representation theorem.

As a matter of terminology, if U is defined by inequality and equality constraints as

$$U = \{v \in \Omega \mid \varphi_i(v) \leq 0, i = 1, \dots, m, \psi_j(v) = 0, j = 1, \dots, p\},$$

if J and all the functions φ_i and ψ_j are affine, the problem is said to be *linear* (or a *linear program*), and otherwise *nonlinear*. If J is of the form

$$J(v) = \langle Av, v \rangle - \langle b, v \rangle$$

where A is a nonzero symmetric positive semidefinite matrix and the constraints are affine, the problem is called a *quadratic programming problem*. If the inner product $\langle -, - \rangle$ is the standard Euclidean inner product, J is also expressed as

$$J(v) = v^\top Av - b^\top v.$$

49.2 Existence of Solutions of an Optimization Problem

We begin with the case where U is a closed but possibly unbounded subset of \mathbb{R}^n . In this case the following type of functions arise.

Definition 49.1. A real-valued function $J: V \rightarrow \mathbb{R}$ defined on a normed vector space V is *coercive* iff for any sequence $(v_k)_{k \geq 1}$ of vectors $v_k \in V$, if $\lim_{k \rightarrow \infty} \|v_k\| = \infty$, then

$$\lim_{k \rightarrow \infty} J(v_k) = +\infty.$$

For example, the function $f(x) = x^2 + 2x$ is coercive, but an affine function $f(x) = ax + b$ is not.

Proposition 49.1. Let U be a nonempty, closed subset of \mathbb{R}^n , and let $J: \mathbb{R}^n \rightarrow \mathbb{R}$ be a continuous function which is coercive if U is unbounded. Then there is at least one element $u \in \mathbb{R}^n$ such that

$$u \in U \quad \text{and} \quad J(u) = \inf_{v \in U} J(v).$$

Proof. Since $U \neq \emptyset$, pick any $u_0 \in U$. Since J is coercive, there is some $r > 0$ such that for all $v \in \mathbb{R}^n$, if $\|v\| > r$ then $J(u_0) < J(v)$. It follows that J is minimized over the set

$$U_0 = U \cap \{v \in \mathbb{R}^n \mid \|v\| \leq r\}.$$

Since U is closed and since the closed ball $\{v \in \mathbb{R}^n \mid \|v\| \leq r\}$ is compact, U_0 is compact, but we know that any continuous function on a compact set has a minimum which is achieved. \square

The key point in the above proof is the fact that U_0 is compact. In order to generalize Proposition 49.1 to the case of an infinite dimensional vector space, we need some additional assumptions, and it turns out that the convexity of U and of the function J is sufficient. The key is that convex, closed and bounded subsets of a Hilbert space are “weakly compact.”

Definition 49.2. Let V be a Hilbert space. A sequence $(u_k)_{k \geq 1}$ of vectors $u_k \in V$ converges weakly if there is some $u \in V$ such that

$$\lim_{k \rightarrow \infty} \langle v, u_k \rangle = \langle v, u \rangle \quad \text{for every } v \in V.$$

Recall that a Hibert space is separable if it has a countable Hilbert basis (see Definition A.4). Also, in a Euclidean space (of finite dimension) V , the inner product induces an isomorphism between V and its dual V^* . In our case, we need the isomorphism \sharp from V^* to V defined such that for every linear form $\omega \in V^*$, the vector $\omega^\sharp \in V$ is uniquely defined by the equation

$$\omega(v) = \langle v, \omega^\sharp \rangle \quad \text{for all } v \in V.$$

In a Hilbert space, the dual space V' is the set of all continuous linear forms $\omega: V \rightarrow \mathbb{R}$, and the existence of the isomorphism \sharp between V' and V is given by the Riesz representation theorem; see Proposition 48.9. This theorem allows a generalization of the notion of gradient. Indeed, if $f: V \rightarrow \mathbb{R}$ is a function defined on the Hilbert space V and if f is differentiable at some point $u \in V$, then by definition, the derivative $df_u: V \rightarrow \mathbb{R}$ is a continuous linear form, so by the Riesz representation theorem (Proposition 48.9) there is a unique vector, denoted $\nabla f_u \in V$, such that

$$df_u(v) = \langle v, \nabla f_u \rangle \quad \text{for all } v \in V.$$

Definition 49.3. The unique vector ∇f_u such that

$$df_u(v) = \langle v, \nabla f_u \rangle \quad \text{for all } v \in V$$

is called the *gradient* of f at u .

Similarly, since the second derivative $D^2 f_u: V \rightarrow V'$ of f induces a continuous symmetric bilinear form from $V \times V$ to \mathbb{R} , by Proposition 48.10, there is a unique continuous self-adjoint linear map $\nabla^2 f_u: V \rightarrow V$ such that

$$D^2 f_u(v, w) = \langle \nabla^2 f_u(v), w \rangle \quad \text{for all } v, w \in V.$$

The map $\nabla^2 f_u$ is a generalization of the *Hessian*.

The next theorem is a rather general result about the existence of minima of convex functions defined on convex domains. The proof is quite involved and can be omitted upon first reading.

Theorem 49.2. *Let U be a nonempty, convex, closed subset of a separable Hilbert space V , and let $J: V \rightarrow \mathbb{R}$ be a convex, differentiable function which is coercive if U is unbounded. Then there is at least one element $u \in V$ such that*

$$u \in U \quad \text{and} \quad J(u) = \inf_{v \in U} J(v).$$

Proof. As in the proof of Proposition 49.1, since the function J is coercive, we may assume that U is bounded and convex (however, if V infinite dimensional, then U is not compact in general). The proof proceeds in four steps.

Step 1. Consider a *minimizing sequence* $(u_k)_{k \geq 0}$, namely a sequence of elements $u_k \in V$ such that

$$u_k \in U \quad \text{for all } k \geq 0, \quad \lim_{k \rightarrow \infty} J(u_k) = \inf_{v \in U} J(v).$$

At this stage, it is possible that $\inf_{v \in U} J(v) = -\infty$, but we will see that this is actually impossible. However, since U is bounded, the sequence $(u_k)_{k \geq 0}$ is bounded. Our goal is to prove that there is some subsequence of $(u_\ell)_{\ell \geq 0}$ of $(u_k)_{k \geq 0}$ that converges weakly.

Since the sequence $(u_k)_{k \geq 0}$ is bounded there is some constant $C > 0$ such that $\|u_k\| \leq C$ for all $k \geq 0$. Then by the Cauchy–Schwarz inequality, for every $v \in V$ we have

$$|\langle v, u_k \rangle| \leq \|v\| \|u_k\| \leq C \|v\|,$$

which shows that the sequence $(\langle v, u_k \rangle)_{k \geq 0}$ is bounded. Since V is a separable Hilbert space, there is a countable family $(v_k)_{k \geq 0}$ of vectors $v_k \in V$ which is dense in V . Since the sequence $(\langle v_1, u_k \rangle)_{k \geq 0}$ is bounded (in \mathbb{R}), we can find a convergent subsequence $(\langle v_1, u_{i_1(j)} \rangle)_{j \geq 0}$. Similarly, since the sequence $(\langle v_2, u_{i_1(j)} \rangle)_{j \geq 0}$ is bounded, we can find a convergent subsequence $(\langle v_2, u_{i_2(j)} \rangle)_{j \geq 0}$, and in general, since the sequence $(\langle v_k, u_{i_{k-1}(j)} \rangle)_{j \geq 0}$ is bounded, we can find a convergent subsequence $(\langle v_k, u_{i_k(j)} \rangle)_{j \geq 0}$.

We obtain the following infinite array:

$$\begin{pmatrix} \langle v_1, u_{i_1(1)} \rangle & \langle v_2, u_{i_2(1)} \rangle & \cdots & \langle v_k, u_{i_k(1)} \rangle & \cdots \\ \langle v_1, u_{i_1(2)} \rangle & \langle v_2, u_{i_2(2)} \rangle & \cdots & \langle v_k, u_{i_k(2)} \rangle & \cdots \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \langle v_1, u_{i_1(k)} \rangle & \langle v_2, u_{i_2(k)} \rangle & \cdots & \langle v_k, u_{i_k(k)} \rangle & \cdots \\ \vdots & \vdots & \vdots & \vdots & \vdots \end{pmatrix}$$

Consider the “diagonal” sequence $(w_\ell)_{\ell \geq 0}$ defined by

$$w_\ell = u_{i_\ell(\ell)}, \quad \ell \geq 0.$$

We are going to prove that for every $v \in V$, the sequence $(\langle v, w_\ell \rangle)_{\ell \geq 0}$ has a limit.

By construction, for every $k \geq 0$, the sequence $(\langle v_k, w_\ell \rangle)_{\ell \geq 0}$ has a limit, which is the limit of the sequence $(\langle v_k, u_{i_k(j)} \rangle)_{j \geq 0}$, since the sequence $(i_\ell(\ell))_{\ell \geq 0}$ is a subsequence of every sequence $(i_\ell(j))_{j \geq 0}$ for every $\ell \geq 0$.

Pick any $v \in V$ and any $\epsilon > 0$. Since $(v_k)_{k \geq 0}$ is dense in V , there is some v_k such that

$$\|v - v_k\| \leq \epsilon/(4C).$$

Then we have

$$\begin{aligned} |\langle v, w_\ell \rangle - \langle v, w_m \rangle| &= |\langle v, w_\ell - w_m \rangle| \\ &= |\langle v_k + v - v_k, w_\ell - w_m \rangle| \\ &= |\langle v_k, w_\ell - w_m \rangle + \langle v - v_k, w_\ell - w_m \rangle| \\ &\leq |\langle v_k, w_\ell \rangle - \langle v_k, w_m \rangle| + |\langle v - v_k, w_\ell - w_m \rangle|. \end{aligned}$$

By Cauchy–Schwarz and since $\|w_\ell - w_m\| \leq \|w_\ell\| + \|w_m\| \leq C + C = 2C$,

$$|\langle v - v_k, w_\ell - w_m \rangle| \leq \|v - v_k\| \|w_\ell - w_m\| \leq (\epsilon/(4C))2C = \epsilon/2,$$

so

$$|\langle v, w_\ell \rangle - \langle v, w_m \rangle| \leq |\langle v_k, w_\ell - w_m \rangle| + \epsilon/2.$$

With the element v_k held fixed, by a previous argument the sequence $(\langle v_k, w_\ell \rangle)_{\ell \geq 0}$ converges, so it is a Cauchy sequence. Consequently there is some ℓ_0 (depending on ϵ and v_k) such that

$$|\langle v_k, w_\ell \rangle - \langle v_k, w_m \rangle| \leq \epsilon/2 \quad \text{for all } \ell, m \geq \ell_0,$$

so we get

$$|\langle v, w_\ell \rangle - \langle v, w_m \rangle| \leq \epsilon/2 + \epsilon/2 = \epsilon \quad \text{for all } \ell, m \geq \ell_0.$$

This proves that the sequence $(\langle v, w_\ell \rangle)_{\ell \geq 0}$ is a Cauchy sequence, and thus it converges.

Define the function $g: V \rightarrow \mathbb{R}$ by

$$g(v) = \lim_{\ell \rightarrow \infty} \langle v, w_\ell \rangle, \quad \text{for all } v \in V.$$

Since

$$|\langle v, w_\ell \rangle| \leq \|v\| \|w_\ell\| \leq C \|v\| \quad \text{for all } \ell \geq 0,$$

we have

$$|g(v)| \leq C \|v\|,$$

so g is a continuous linear map. By the Riesz representation theorem (Proposition 48.9), there is a unique $u \in V$ such that

$$g(v) = \langle v, u \rangle \quad \text{for all } v \in V,$$

which shows that

$$\lim_{\ell \rightarrow \infty} \langle v, w_\ell \rangle = \langle v, u \rangle \quad \text{for all } v \in V,$$

namely the subsequence $(w_\ell)_{\ell \geq 0}$ of the sequence $(u_k)_{k \geq 0}$ converges weakly to $u \in V$.

Step 2. We prove that the “weak limit” u of the sequence $(w_\ell)_{\ell \geq 0}$ belongs to U .

Consider the projection $p_U(u)$ of $u \in V$ onto the closed convex set U . Since $w_\ell \in U$, by Proposition 48.5(2) and the fact that U is convex and closed, we have

$$\langle p_U(u) - u, w_\ell - p_U(u) \rangle \geq 0 \quad \text{for all } \ell \geq 0.$$

The weak convergence of the sequence $(w_\ell)_{\ell \geq 0}$ to u implies that

$$\begin{aligned} 0 &\leq \lim_{\ell \rightarrow \infty} \langle p_U(u) - u, w_\ell - p_U(u) \rangle = \langle p_U(u) - u, u - p_U(u) \rangle \\ &= -\|p_U(u) - u\| \leq 0, \end{aligned}$$

so $\|p_U(u) - u\| = 0$, which means that $p_U(u) = u$, and so $u \in U$.

Step 3. We prove that

$$J(v) \leq \liminf_{\ell \rightarrow \infty} J(z_\ell)$$

for every sequence $(z_\ell)_{\ell \geq 0}$ converging weakly to some element $v \in V$.

Since J is assumed to be differentiable and convex, by Proposition 40.11(1) we have

$$J(v) + \langle \nabla J_v, z_\ell - v \rangle \leq J(z_\ell) \quad \text{for all } \ell \geq 0,$$

and by definition of weak convergence

$$\lim_{\ell \rightarrow \infty} \langle \nabla J_v, z_\ell \rangle = \langle \nabla J_v, v \rangle,$$

so $\lim_{\ell \rightarrow \infty} \langle \nabla J_v, z_\ell - v \rangle = 0$, and by definition of \liminf we get

$$J(v) \leq \liminf_{\ell \rightarrow \infty} J(z_\ell)$$

for every sequence $(z_\ell)_{\ell \geq 0}$ converging weakly to some element $v \in V$.

Step 4. The weak limit $u \in U$ of the subsequence $(w_\ell)_{\ell \geq 0}$ extracted from the minimizing sequence $(u_k)_{k \geq 0}$ satisfies the equation

$$J(u) = \inf_{v \in U} J(v).$$

By Step (1) and Step (2) the subsequence $(w_\ell)_{\ell \geq 0}$ of the sequence $(u_k)_{k \geq 0}$ converges weakly to some element $u \in U$, so by Step (3) we have

$$J(u) \leq \liminf_{\ell \rightarrow \infty} J(w_\ell).$$

On the other hand, by definition of $(w_\ell)_{\ell \geq 0}$ as a subsequence of $(u_k)_{k \geq 0}$, since the sequence $(J(u_k))_{k \geq 0}$ converges to $J(v)$, we have

$$J(u) \leq \liminf_{\ell \rightarrow \infty} J(w_\ell) = \lim_{k \rightarrow \infty} J(u_k) = \inf_{v \in U} J(v),$$

which proves that $u \in U$ achieves the minimum of J on U . \square

Remark: Theorem 49.2 still holds if we only assume that J is convex and continuous. It also holds in a reflexive Banach space, of which Hilbert spaces are a special case; see Brezis [31], Corollary 3.23.

Theorem 49.2 is a rather general theorem whose proof is quite involved. For functions J of a certain type, we can obtain existence and uniqueness results that are easier to prove. This is true in particular for quadratic functionals.

49.3 Minima of Quadratic Functionals

Definition 49.4. Let V be a real Hilbert space. A function $J: V \rightarrow \mathbb{R}$ is called a *quadratic functional* if it is of the form

$$J(v) = \frac{1}{2}a(v, v) - h(v),$$

where $a: V \times V \rightarrow \mathbb{R}$ is a bilinear form which is symmetric and continuous, and $h: V \rightarrow \mathbb{R}$ is a continuous linear form.

Definition 49.4 is a natural extension of the notion of a quadratic functional on \mathbb{R}^n . Indeed, by Proposition 48.10, there is a unique continuous self-adjoint linear map $A: V \rightarrow V$ such that

$$a(u, v) = \langle Au, v \rangle \quad \text{for all } u, v \in V,$$

and by the Riesz representation theorem (Proposition 48.9), there is a unique $b \in V$ such that

$$h(v) = \langle b, v \rangle \quad \text{for all } v \in V.$$

Consequently, J can be written as

$$J(v) = \frac{1}{2} \langle Av, v \rangle - \langle b, v \rangle \quad \text{for all } v \in V. \quad (1)$$

Since a is bilinear and h is linear, by Propositions 39.3 and 39.5, observe that the derivative of J is given by

$$dJ_u(v) = a(u, v) - h(v) \quad \text{for all } v \in V,$$

or equivalently by

$$dJ_u(v) = \langle Au, v \rangle - \langle b, v \rangle = \langle Au - b, v \rangle, \quad \text{for all } v \in V.$$

Thus the gradient of J is given by

$$\nabla J_u = Au - b, \quad (2)$$

just as in the case of a quadratic function of the form $J(v) = (1/2)v^\top Av - b^\top v$, where A is a symmetric $n \times n$ matrix and $b \in \mathbb{R}^n$. To find the second derivative $D^2 J_u$ of J at u we compute

$$dJ_{u+v}(w) - dJ_u(w) = a(u + v, w) - h(w) - (a(u, w) - h(w)) = a(v, w),$$

so

$$D^2 J_u(v, w) = a(v, w) = \langle Av, w \rangle,$$

which yields

$$\nabla^2 J_u = A. \quad (3)$$

We will also make use of the following formula.

Proposition 49.3. *If J is a quadratic functional, then*

$$J(u + \rho v) = \frac{\rho^2}{2} a(v, v) + \rho(a(u, v) - h(v)) + J(u).$$

Proof. Since a is symmetric bilinear and h is linear, we have

$$\begin{aligned} J(u + \rho v) &= \frac{1}{2}a(u + \rho v, u + \rho v) - h(u + \rho v) \\ &= \frac{\rho^2}{2}a(v, v) + \rho a(u, v) + \frac{1}{2}a(u, u) - h(u) - \rho h(v) \\ &= \frac{\rho^2}{2}a(v, v) + \rho(a(u, v) - h(v)) + J(u). \end{aligned}$$

Since $dJ_u(v) = a(u, v) - h(v) = \langle Au - b, v \rangle$ and $\nabla J_u = Au - b$, we can also write

$$J(u + \rho v) = \frac{\rho^2}{2}a(v, v) + \rho\langle \nabla J_u, v \rangle + J(u),$$

as claimed. \square

We have the following theorem about the existence and uniqueness of minima of quadratic functionals.

Theorem 49.4. *Given any real Hilbert space V , let $J: V \rightarrow \mathbb{R}$ be a quadratic functional of the form*

$$J(v) = \frac{1}{2}a(v, v) - h(v).$$

Assume that there is some real number $\alpha > 0$ such that

$$a(v, v) \geq \alpha \|v\|^2 \quad \text{for all } v \in V. \quad (*_\alpha)$$

If U is any nonempty, closed, convex subset of V , then there is a unique $u \in U$ such that

$$J(u) = \inf_{v \in U} J(v).$$

The element $u \in U$ satisfies the condition

$$a(u, v - u) \geq h(v - u) \quad \text{for all } v \in U. \quad (*)$$

Conversely (with the same assumptions on U as above), if an element $u \in U$ satisfies $()$, then*

$$J(u) = \inf_{v \in U} J(v).$$

If U is a subspace of V , then the above inequalities are replaced by the equations

$$a(u, v) = h(v) \quad \text{for all } v \in U. \quad (**)$$

Proof. The key point is that the bilinear form a is actually an inner product in V . This is because it is positive definite, since $(*_\alpha)$ implies that

$$\sqrt{\alpha} \|v\| \leq (a(v, v))^{1/2},$$

and on the other hand the continuity of a implies that

$$a(v, v) \leq \|a\| \|v\|^2,$$

so we get

$$\sqrt{\alpha} \|v\| \leq (a(v, v))^{1/2} \leq \sqrt{\|a\|} \|v\|.$$

The above also shows that the norm $v \mapsto (a(v, v))^{1/2}$ induced by the inner product a is equivalent to the norm induced by the inner product $\langle -, - \rangle$ on V . Thus h is still continuous with respect to the norm $v \mapsto (a(v, v))^{1/2}$. Then by the Riesz representation theorem (Proposition 48.9), there is some unique $c \in V$ such that

$$h(v) = a(c, v) \quad \text{for all } v \in V.$$

Consequently, we can express $J(v)$ as

$$J(v) = \frac{1}{2}a(v, v) - a(c, v) = \frac{1}{2}a(v - c, v - c) - \frac{1}{2}a(c, c).$$

But then minimizing $J(v)$ over U is equivalent to minimizing $(a(v - c, v - c))^{1/2}$ over $v \in U$, and by the projection lemma (Proposition 48.5(1)) this is equivalent to finding the projection $p_U(c)$ of c on the closed convex set U with respect to the inner product a . Therefore, there is a unique $u = p_U(c) \in U$ such that

$$J(u) = \inf_{v \in U} J(v).$$

Also by Proposition 48.5(2), this unique element $u \in U$ is characterized by the condition

$$a(u - c, v - u) \geq 0 \quad \text{for all } v \in U.$$

Since

$$a(u - c, v - u) = a(u, v - u) - a(c, v - u) = a(u, v - u) - h(v - u),$$

the above inequality is equivalent to

$$a(u, v - u) \geq h(v - u) \quad \text{for all } v \in U. \tag{*}$$

If U is a subspace of V , then by Proposition 48.5(3) we have the condition

$$a(u - c, v) = 0 \quad \text{for all } v \in U,$$

which is equivalent to

$$a(u, v) = a(c, v) = h(v) \quad \text{for all } v \in U, \tag{**}$$

a claimed. □

Note that the symmetry of the bilinear form a played a crucial role. Also, the inequalities

$$a(u, v - u) \geq h(v - u) \quad \text{for all } v \in U$$

are sometimes called *variational inequalities*.

Definition 49.5. A bilinear form $a: V \times V \rightarrow \mathbb{R}$ such that there is some real $\alpha > 0$ such that

$$a(v, v) \geq \alpha \|v\|^2 \quad \text{for all } v \in V$$

is said to be *coercive*.

Theorem 49.4 is the special case of Stampacchia's theorem and the Lax–Milgram theorem when $U = V$, and where a is a symmetric bilinear form. To prove Stampacchia's theorem in general, we need to recall the *contraction mapping theorem*.

Definition 49.6. Let (E, d) be a metric space. A map $f: E \rightarrow E$ is a *contraction* (or a *contraction mapping*) if there is some real number k such that $0 \leq k < 1$ and

$$d(f(u), f(v)) \leq kd(u, v) \quad \text{for all } u, v \in E.$$

The number k is often called a *Lipschitz constant*.

The following theorem is proven in Section 37.10; see Theorem 37.54. A proof can be also found in Apostol [4], Dixmier [51], or Schwartz [150], among many sources. For the reader's convenience we restate this theorem.

Theorem 49.5. (Contraction Mapping Theorem) *Let (E, d) be a complete metric space. Every contraction $f: E \rightarrow E$ has a unique fixed point (that is, an element $u \in E$ such that $f(u) = u$).*

The contraction mapping theorem is also known as the *Banach fixed point theorem*.

Theorem 49.6. (Lions–Stampacchia) *Given a Hilbert space V , let $a: V \times V \rightarrow \mathbb{R}$ be a continuous bilinear form (not necessarily symmetric), let $h \in V'$ be a continuous linear form, and let J be given by*

$$J(v) = \frac{1}{2} a(v, v) - h(v), \quad v \in V.$$

If a is coercive, then for every nonempty, closed, convex subset U of V , there is a unique $u \in U$ such that

$$a(u, v - u) \geq h(v - u) \quad \text{for all } v \in U. \tag{*}$$

If a is symmetric, then $u \in U$ is the unique element of U such that

$$J(u) = \inf_{v \in U} J(v).$$

Proof. As discussed just after Definition 49.4, by Proposition 48.10, there is a unique continuous linear map $A: V \rightarrow V$ such that

$$a(u, v) = \langle Au, v \rangle \quad \text{for all } u, v \in V,$$

with $\|A\| = \|a\| = C$, and by the Riesz representation theorem (Proposition 48.9), there is a unique $b \in V$ such that

$$h(v) = \langle b, v \rangle \quad \text{for all } v \in V.$$

Consequently, J can be written as

$$J(v) = \frac{1}{2} \langle Av, v \rangle - \langle b, v \rangle \quad \text{for all } v \in V. \quad (*_1)$$

Since $\|A\| = \|a\| = C$, we have $\|Av\| \leq \|A\| \|v\| = C \|v\|$ for all $v \in V$. Using $(*_1)$, the inequality $(*)$ is equivalent to finding u such that

$$\langle Au, v - u \rangle \geq \langle b, v - u \rangle \quad \text{for all } v \in U. \quad (*_2)$$

Let $\rho > 0$ be a constant to be determined later. Then $(*_2)$ is equivalent to

$$\langle \rho b - \rho Au + u - u, v - u \rangle \leq 0 \quad \text{for all } v \in U. \quad (*_3)$$

By the projection lemma (Proposition 48.5 (1) and (2)), $(*_3)$ is equivalent to finding $u \in U$ such that

$$u = p_U(\rho b - \rho Au + u). \quad (*_4)$$

We are led to finding a fixed point of the function $F: U \rightarrow U$ given by

$$F(v) = p_U(\rho b - \rho Av + v).$$

By Proposition 48.6, the projection map p_U does not increase distance, so

$$\|F(v_1) - F(v_2)\| \leq \|v_1 - v_2 - \rho(Av_1 - Av_2)\|.$$

Since a is coercive we have

$$a(v, v) \geq \alpha \|v\|^2,$$

since $a(v, v) = \langle Av, v \rangle$ we have

$$\langle Av, v \rangle \geq \alpha \|v\|^2 \quad \text{for all } v \in V, \quad (*_5)$$

and since

$$\|Av\| \leq C \|v\| \quad \text{for all } v \in V, \quad (*_6)$$

we get

$$\begin{aligned} \|F(v_1) - F(v_2)\|^2 &\leq \|v_1 - v_2\|^2 - 2\rho \langle Av_1 - Av_2, v_1 - v_2 \rangle + \rho^2 \|Av_1 - Av_2\|^2 \\ &\leq \left(1 - 2\rho\alpha + \rho^2 C^2\right) \|v_1 - v_2\|^2. \end{aligned}$$

If we pick $\rho > 0$ such that $\rho < 2\alpha/C^2$, then

$$k^2 = 1 - 2\rho\alpha + \rho^2C^2 < 1,$$

and then

$$\|F(v_1) - F(v_2)\| \leq k \|v_1 - v_2\|, \quad (*_7)$$

with $0 \leq k < 1$, which shows that F is a contraction. By Theorem 49.5, the map F has a unique fixed point $u \in U$, which concludes the proof of the first statement. If a is also symmetric, then the second statement is just the first part of Theorem 49.4. \square

Remark: Many physical problems can be expressed in terms of an unknown function u that satisfies some inequality

$$a(u, v - u) \geq h(v - u) \quad \text{for all } v \in U,$$

for some set U of “admissible” functions which is closed and convex. The bilinear form a and the linear form h are often given in terms of integrals. The above inequality is called a *variational inequality*.

In the special case where $U = V$ we obtain the Lax–Milgram theorem.

Theorem 49.7. (Lax–Milgram’s Theorem) *Given a Hilbert space V , let $a: V \times V \rightarrow \mathbb{R}$ be a continuous bilinear form (not necessarily symmetric), let $h \in V'$ be a continuous linear form, and let J be given by*

$$J(v) = \frac{1}{2}a(v, v) - h(v), \quad v \in V.$$

If a is coercive, which means that there is some $\alpha > 0$ such that

$$a(v, v) \geq \alpha \|v\|^2 \quad \text{for all } v \in V,$$

then there is a unique $u \in V$ such that

$$a(u, v) = h(v) \quad \text{for all } v \in V.$$

If a is symmetric, then $u \in V$ is the unique element of V such that

$$J(u) = \inf_{v \in V} J(v).$$

The Lax–Milgram theorem plays an important role in solving linear elliptic partial differential equations; see Brezis [31].

We now consider various methods, known as gradient descents, to find minima of certain types of functionals.

49.4 Elliptic Functionals

We begin by defining the notion of an elliptic functional which generalizes the notion of a quadratic function defined by a symmetric positive definite matrix. Elliptic functionals are well adapted to the types of iterative methods described in this section and lend themselves well to an analysis of the convergence of these methods.

Definition 49.7. Given a Hilbert space V , a functional $J: V \rightarrow \mathbb{R}$ is said to be *elliptic* if it is continuously differentiable on V , and if there is some constant $\alpha > 0$ such that

$$\langle \nabla J_v - \nabla J_u, v - u \rangle \geq \alpha \|v - u\|^2 \quad \text{for all } u, v \in V.$$

The following proposition gathers properties of elliptic functionals that will be used later to analyze the convergence of various gradient descent methods.

Theorem 49.8. Let V be a Hilbert space.

- (1) An elliptic functional $J: V \rightarrow \mathbb{R}$ is strictly convex and coercive. Furthermore, it satisfies the identity

$$J(v) - J(u) \geq \langle \nabla J_u, v - u \rangle + \frac{\alpha}{2} \|v - u\|^2 \quad \text{for all } u, v \in V.$$

- (2) If U is a nonempty, convex, closed subset of the Hilbert space V and if J is an elliptic functional, then Problem (P),

$$\begin{aligned} &\text{find } u \\ &\text{such that } u \in U \text{ and } J(u) = \inf_{v \in U} J(v) \end{aligned}$$

has a unique solution.

- (3) Suppose the set U is convex and that the functional J is elliptic. Then an element $u \in U$ is a solution of Problem (P) if and only if it satisfies the condition

$$\langle \nabla J_u, v - u \rangle \geq 0 \quad \text{for every } v \in U$$

in the general case, or

$$\nabla J_u = 0 \text{ if } U = V.$$

- (4) A functional J which is twice differentiable in V is elliptic if and only if

$$\langle \nabla^2 J_u(w), w \rangle \geq \alpha \|w\|^2 \quad \text{for all } u, w \in V.$$

Proof. (1) Since J is a C^1 -function, by Taylor's formula with integral remainder in the case $m = 0$ (Theorem 39.26), we get

$$\begin{aligned} J(v) - J(u) &= \int_0^1 dJ_{u+t(v-u)}(v-u) dt \\ &= \int_0^1 \langle \nabla J_{u+t(v-u)}, v-u \rangle dt \\ &= \langle \nabla J_u, v-u \rangle + \int_0^1 \langle \nabla J_{u+t(v-u)} - \nabla J_u, v-u \rangle dt \\ &= \langle \nabla J_u, v-u \rangle + \int_0^1 \frac{\langle \nabla J_{u+t(v-u)} - \nabla J_u, t(v-u) \rangle}{t} dt \\ &\geq \langle \nabla J_u, v-u \rangle + \int_0^1 \alpha t \|v-u\|^2 dt \quad \text{since } J \text{ is elliptic} \\ &= \langle \nabla J_u, v-u \rangle + \frac{\alpha}{2} \|v-u\|^2. \end{aligned}$$

Using the inequality

$$J(v) - J(u) \geq \langle \nabla J_u, v-u \rangle + \frac{\alpha}{2} \|v-u\|^2 \quad \text{for all } u, v \in V,$$

by Proposition 40.11(2), since

$$J(v) > J(u) + \langle \nabla J_u, v-u \rangle \quad \text{for all } u, v \in V, v \neq u,$$

the function J is strictly convex. It is coercive because (using Cauchy–Schwarz)

$$\begin{aligned} J(v) &\geq J(0) + \langle \nabla J_0, v \rangle + \frac{\alpha}{2} \|v\|^2 \\ &\geq J(0) - \|\nabla J_0\| \|v\| + \frac{\alpha}{2} \|v\|^2, \end{aligned}$$

and the term $(-\|\nabla J_0\| + \frac{\alpha}{2} \|v\|) \|v\|$ goes to $+\infty$ when $\|v\|$ tends to $+\infty$.

(2) Since by (1) the functional J is coercive, by Theorem 49.2, Problem (P) has a solution. Since J is strictly convex, by Theorem 40.13(2), it has a unique minimum.

(3) These are just the conditions of Theorem 40.13(3, 4).

(4) If J is twice differentiable, we showed in Section 39.6 that we have

$$D^2 J_u(w, w) = D_w(DJ)(u) = \lim_{\theta \rightarrow 0} \frac{DJ_{u+\theta w}(w) - DJ_u(w)}{\theta},$$

and since

$$\begin{aligned} D^2 J_u(w, w) &= \langle \nabla^2 J_u(w), w \rangle \\ DJ_{u+\theta w}(w) &= \langle \nabla J_{u+\theta w}, w \rangle \\ DJ_u(w) &= \langle \nabla J_u, w \rangle, \end{aligned}$$

and since J is elliptic, for all $u, w \in V$ we can write

$$\begin{aligned}\langle \nabla^2 J_u(w), w \rangle &= \lim_{\theta \rightarrow 0} \frac{\langle \nabla J_{u+\theta w} - \nabla J_u, w \rangle}{\theta} \\ &= \lim_{\theta \rightarrow 0} \frac{\langle \nabla J_{u+\theta w} - \nabla J_u, \theta w \rangle}{\theta^2} \\ &\geq \theta \|w\|^2.\end{aligned}$$

Conversely, assume that the condition

$$\langle \nabla^2 J_u(w), w \rangle \geq \alpha \|w\|^2 \quad \text{for all } u, w \in V$$

holds. If we define the function $g: V \rightarrow \mathbb{R}$ by

$$g(w) = \langle \nabla J_w, v - u \rangle = dJ_w(v - u) = D_{v-u}J(w),$$

where u and v are fixed vectors in V , then we have

$$dg_{u+\theta(v-u)}(v-u) = D_{v-u}g(u+\theta(v-u)) = D_{v-u}D_{v-u}J(u+\theta(v-u)) = D^2J_{u+\theta(v-u)}(v-u, v-u)$$

and we can apply the Taylor–MacLaurin formula (Theorem 39.25 with $m = 0$) to g , and we get

$$\begin{aligned}\langle \nabla J_v - \nabla J_u, v - u \rangle &= g(v) - g(u) \\ &= dg_{u+\theta(v-u)}(v-u) \quad (0 < \theta < 1) \\ &= D^2J_{u+\theta(v-u)}(v-u, v-u) \\ &= \langle \nabla^2 J_{u+\theta(v-u)}(v-u), v-u \rangle \\ &\geq \alpha \|v-u\|^2,\end{aligned}$$

which shows that J is elliptic. □

Corollary 49.9. *If $J: \mathbb{R}^n \rightarrow \mathbb{R}$ is a quadratic function given by*

$$J(v) = \frac{1}{2} \langle Av, v \rangle - \langle b, v \rangle$$

(where A is a symmetric $n \times n$ matrix and $\langle -, - \rangle$ is the standard Euclidean inner product), then J is elliptic iff A is positive definite.

This a consequence of Theorem 49.8 because

$$\langle \nabla^2 J_u(w), w \rangle = \langle Aw, w \rangle \geq \lambda_1 \|w\|^2$$

where λ_1 is the smallest eigenvalue of A ; see Proposition 17.24 (Rayleigh–Ritz). Note that by Proposition 17.24 (Rayleigh–Ritz), we also have the following corollary.

Corollary 49.10. *If $J: \mathbb{R}^n \rightarrow \mathbb{R}$ is a quadratic function given by*

$$J(v) = \frac{1}{2} \langle Av, v \rangle - \langle b, v \rangle$$

then

$$\langle \nabla^2 J_u(w), w \rangle \leq \lambda_n \|w\|^2$$

where λ_n is the largest eigenvalue of A ;

The above fact will be useful later on.

Similarly, given a quadratic functional J defined on a Hilbert space V , where

$$J(v) = \frac{1}{2} a(v, v) - h(v),$$

by Theorem 49.8 (4), the functional J is elliptic iff there is some $\alpha > 0$ such that

$$\langle \nabla^2 J_u(v), v \rangle = a(v, v) \geq \alpha \|v\|^2 \quad \text{for all } v \in V.$$

This is precisely the hypothesis $(*_\alpha)$ used in Theorem 49.4.

49.5 Iterative Methods for Unconstrained Problems

We will now describe methods for solving unconstrained minimization problems, that is, finding the minimum (or minima) of a functions J over the whole space V . These methods are *iterative*, which means that given some *initial* vector u_0 , we construct a sequence $(u_k)_{k \geq 0}$ that converges to a minimum u of the function J .

The key step is define u_{k+1} from u_k , and a first idea is to reduce the problem to a simpler problem, namely the minimization of a function of a *single (real) variable*. For this, we need two perform two steps:

- (1) Find a *descent direction* at u_k , which is a some nonzero vector d_k which is usually determined from the gradient of J at various points. The descent direction d_k must satisfy the inequality $\langle \nabla J_{u_k}, d_k \rangle < 0$.
- (2) *Exact line search:* Find the minimum of the restriction of the function J along the line through u_k and parallel to the direction d_k . This means finding a real $\rho_k \in \mathbb{R}$ (depending on u_k and d_k) such that

$$J(u_k + \rho_k d_k) = \inf_{\rho \in \mathbb{R}} J(u_k + \rho d_k).$$

Typically, $\rho_k > 0$. This problem only succeeds if ρ_k is *unique*, in which case we set

$$u_{k+1} = u_k + \rho_k d_k.$$

This step is often called a *line search* or *line minimization*, and ρ_k is called the *stepsize* parameter. See Figure 49.1.

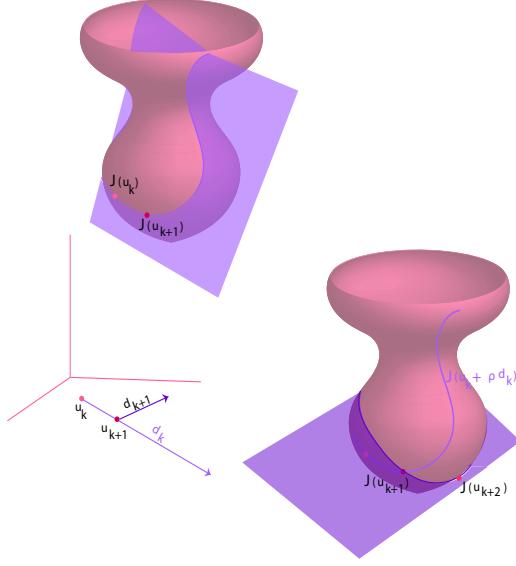

Figure 49.1: Let $J: \mathbb{R}^2 \rightarrow \mathbb{R}$ be the function whose graph is represented by the pink surface. Given a point u_k in the xy -plane, and a direction d_k , we calculate first u_{k+1} and then u_{k+2} .

Proposition 49.11. *If J is a quadratic elliptic functional of the form*

$$J(v) = \frac{1}{2}a(v, v) - h(v),$$

then given d_k , there is a unique ρ_k solving the line search in Step (2).

Proof. This is because, by Proposition 49.3, we have

$$J(u_k + \rho d_k) = \frac{\rho^2}{2}a(d_k, d_k) + \rho\langle \nabla J_{u_k}, d_k \rangle + J(u_k),$$

and since $a(d_k, d_k) > 0$ (because J is elliptic), the above function of ρ has a unique minimum when its derivative is zero, namely

$$\rho a(d_k, d_k) + \langle \nabla J_{u_k}, d_k \rangle = 0. \quad \square$$

Since Step (2) is often too costly, an alternative is

(3) *Backtracking line search:* Pick two constants α and β such that $0 < \alpha < 1/2$ and $0 < \beta < 1$, and set $t = 1$. Given a descent direction d_k at $u_k \in \text{dom}(J)$,

while $J(u_k + td_k) > J(u_k) + \alpha t \langle \nabla J_{u_k}, d_k \rangle$ **do** $t := \beta t$;
 $\rho_k = t$; $u_{k+1} = u_k + \rho_k d_k$.

Since d_k is a descent direction, we must have $\langle \nabla J_{u_k}, d_k \rangle < 0$, so for t small enough the condition $J(u_k + td_k) \leq J(u_k) + \alpha t \langle \nabla J_{u_k}, d_k \rangle$ will hold and the search will stop. It can be shown that the exit inequality $J(u_k + td_k) \leq J(u_k) + \alpha t \langle \nabla J_{u_k}, d_k \rangle$ holds for all $t \in (0, t_0]$, for some $t_0 > 0$. Thus the backtracking line search stops with a step length ρ_k that satisfies $\rho_k = 1$ or $\rho_k \in (\beta t_0, t_0]$. Care has to be exercised so that $u_k + \rho_k d_k \in \text{dom}(J)$. For more details, see Boyd and Vandenberghe [29] (Section 9.2).

We now consider one of the simplest methods for choosing the directions of descent in the case where $V = \mathbb{R}^n$, which is to pick the directions of the coordinate axes in a cyclic fashion. Such a method is called the *method of relaxation*.

If we write

$$u_k = (u_1^k, u_2^k, \dots, u_n^k),$$

then the components u_i^{k+1} of u_{k+1} are computed in terms of u_k by solving from top down the following system of equations:

$$\begin{aligned} J(\mathbf{u}_1^{k+1}, u_2^k, u_3^k, \dots, u_n^k) &= \inf_{\lambda \in \mathbb{R}} J(\lambda, u_2^k, u_3^k, \dots, u_n^k) \\ J(u_1^{k+1}, \mathbf{u}_2^{k+1}, u_3^k, \dots, u_n^k) &= \inf_{\lambda \in \mathbb{R}} J(u_1^{k+1}, \lambda, u_3^k, \dots, u_n^k) \\ &\vdots \\ J(u_1^{k+1}, \dots, u_{n-1}^{k+1}, \mathbf{u}_n^{k+1}) &= \inf_{\lambda \in \mathbb{R}} J(u_1^{k+1}, \dots, u_{n-1}^{k+1}, \lambda). \end{aligned}$$

Another and more informative way to write the above system is to define the vectors $u_{k;i}$ by

$$\begin{aligned} u_{k;0} &= (u_1^k, u_2^k, \dots, u_n^k) \\ u_{k;1} &= (u_1^{k+1}, u_2^k, \dots, u_n^k) \\ &\vdots \\ u_{k;i} &= (u_1^{k+1}, \dots, u_i^{k+1}, u_{i+1}^k, \dots, u_n^k) \\ &\vdots \\ u_{k;n} &= (u_1^{k+1}, u_2^{k+1}, \dots, u_n^{k+1}). \end{aligned}$$

Note that $u_{k;0} = u_k$ and $u_{k;n} = u_{k+1}$. Then our minimization problem can be written as

$$\begin{aligned} J(u_{k;1}) &= \inf_{\lambda \in \mathbb{R}} J(u_{k;0} + \lambda e_1) \\ &\vdots \\ J(u_{k;i}) &= \inf_{\lambda \in \mathbb{R}} J(u_{k;i-1} + \lambda e_i) \\ &\vdots \\ J(u_{k;n}) &= \inf_{\lambda \in \mathbb{R}} J(u_{k;n-1} + \lambda e_n), \end{aligned}$$

where e_i denotes the i th canonical basis vector in \mathbb{R}^n . If J is differentiable, necessary conditions for a minimum, which are also sufficient if J is convex, is that the directional derivatives $dJ_v(e_i)$ be all zero, that is,

$$\langle \nabla J_v, e_i \rangle = 0 \quad i = 0, \dots, n.$$

The following result regarding the convergence of the method of relaxation is proven in Ciarlet [41] (Chapter 8, Theorem 8.4.2).

Proposition 49.12. *If the functional $J: \mathbb{R}^n \rightarrow \mathbb{R}$ is elliptic, then the relaxation method converges.*

Remarks: The proof of Proposition 49.12 uses Theorem 49.8. The finite dimensionality of \mathbb{R}^n also plays a crucial role. The differentiability of the function J is also crucial. Examples where the method loops forever if J is not differentiable can be given; see Ciarlet [41] (Chapter 8, Section 8.4). The proof of Proposition 49.12 yields an *a priori* bound on the error $\|u - u_k\|$. If J is a quadratic functional

$$J(v) = \frac{1}{2}v^\top Av - b^\top v,$$

where A is a symmetric positive definite matrix, then $\nabla J_v = Av - b$, so the above method for solving for u_{k+1} in terms of u_k becomes the *Gauss–Seidel method* for solving a linear system; see Section 10.3.

We now discuss gradient methods.

49.6 Gradient Descent Methods for Unconstrained Problems

The intuition behind these methods is that the convergence of an iterative method ought to be better if the difference $J(u_k) - J(u_{k+1})$ is as large as possible during every iteration step. To achieve this, it is natural to pick the descent direction to be the one *in the opposite direction of the gradient vector ∇J_{u_k}* . This choice is justified by the fact that we can write

$$J(u_k + w) = J(u_k) + \langle \nabla J_{u_k}, w \rangle + \epsilon(w) \|w\|, \quad \text{with } \lim_{w \rightarrow 0} \epsilon(w) = 0.$$

If $\nabla J_{u_k} \neq 0$, the first-order part of the variation of the function J is bounded in absolute value by $\|\nabla J_{u_k}\| \|w\|$ (by the Cauchy–Schwarz inequality), with equality if ∇J_{u_k} and w are collinear.

Gradient descent methods pick the direction of descent to be $d_k = -\nabla J_{u_k}$, so that we have

$$u_{k+1} = u_k - \rho_k \nabla J_{u_k},$$

where we put a negative sign in front of the variable ρ_k as a reminder that the descent direction is *opposite* to that of the gradient; a positive value is expected for the scalar ρ_k .

There are four standard methods to pick ρ_k :

- (1) *Gradient method with fixed stepsize parameter.* This is the simplest and cheapest method which consists of using the *same* constant $\rho_k = \rho$ for all iterations.
- (2) *Gradient method with variable stepsize parameter.* In this method, the parameter ρ_k is adjusted in the course of iterations according to various criteria.
- (3) *Gradient method with optimal stepsize parameter*, also called *steepest descent method for the Euclidean norm*. This is a version of Method 2 in which ρ_k is determined by the following line search:

$$J(u_k - \rho_k \nabla J_{u_k}) = \inf_{\rho \in \mathbb{R}} J(u_k - \rho \nabla J_{u_k}).$$

This optimization problem only succeeds if the above minimization problem has a *unique* solution.

- (4) *Gradient descent method with backtracking line search.* In this method, the step parameter is obtained by performing a backtracking line search.

We have the following useful result about the convergence of the gradient method with optimal parameter.

Proposition 49.13. *Let $J: \mathbb{R}^n \rightarrow \mathbb{R}$ be an elliptic functional. Then the gradient method with optimal stepsize parameter converges.*

Proof. Since J is elliptic, by Theorem 49.8(3), the functional J has a unique minimum u characterized by $\nabla J_u = 0$. Our goal is to prove that the sequence $(u_k)_{k \geq 0}$ constructed using the gradient method with optimal parameter converges to u , starting from any initial vector u_0 . Without loss of generality we may assume that $u_{k+1} \neq u_k$ and $\nabla J_{u_k} \neq 0$ for all k , since otherwise the method converges in a finite number of steps.

Step 1. Show that any two consecutive descent directions are *orthogonal* and

$$J(u_k) - J(u_{k+1}) \geq \frac{\alpha}{2} \|u_k - u_{k+1}\|^2.$$

Let $\varphi_k: \mathbb{R} \rightarrow \mathbb{R}$ be the function given by

$$\varphi_k(\rho) = J(u_k - \rho \nabla J_{u_k}).$$

Since the function φ_k is strictly convex and coercive, by Theorem 49.8(2), it has a unique minimum ρ_k which is the unique solution of the equation $\varphi'_k(\rho) = 0$. By the chain rule

$$\begin{aligned} \varphi'_k(\rho) &= dJ_{u_k - \rho \nabla J_{u_k}}(-\nabla J_{u_k}) \\ &= -\langle \nabla J_{u_k - \rho \nabla J_{u_k}}, \nabla J_{u_k} \rangle, \end{aligned}$$

and since $u_{k+1} = u_k - \rho_k \nabla J_{u_k}$ we get

$$\langle \nabla J_{u_{k+1}}, \nabla J_{u_k} \rangle = 0,$$

which shows that two consecutive descent directions are orthogonal.

Since $u_{k+1} = u_k - \rho_k \nabla J_{u_k}$ and we assumed that $u_{k+1} \neq u_k$, we have $\rho_k \neq 0$, and we also get

$$\langle \nabla J_{u_{k+1}}, u_{k+1} - u_k \rangle = 0.$$

By the inequality of Theorem 49.8(1) we have

$$J(u_k) - J(u_{k+1}) \geq \frac{\alpha}{2} \|u_k - u_{k+1}\|^2.$$

Step 2. Show that $\lim_{k \rightarrow \infty} \|u_k - u_{k+1}\| = 0$.

It follows from the inequality proven in Step 1 that the sequence $(J(u_k))_{k \geq 0}$ is decreasing and bounded below (by $J(u)$, where u is the minimum of J), so it converges and we conclude that

$$\lim_{k \rightarrow \infty} (J(u_k) - J(u_{k+1})) = 0,$$

which combined with the preceding inequality shows that

$$\lim_{k \rightarrow \infty} \|u_k - u_{k+1}\| = 0.$$

Step 3. Show that $\|\nabla J_{u_k}\| \leq \|\nabla J_{u_k} - \nabla J_{u_{k+1}}\|$.

Using the orthogonality of consecutive descent directions, by Cauchy–Schwarz we have

$$\begin{aligned} \|\nabla J_{u_k}\|^2 &= \langle \nabla J_{u_k}, \nabla J_{u_k} - \nabla J_{u_{k+1}} \rangle \\ &\leq \|\nabla J_{u_k}\| \|\nabla J_{u_k} - \nabla J_{u_{k+1}}\|, \end{aligned}$$

so that

$$\|\nabla J_{u_k}\| \leq \|\nabla J_{u_k} - \nabla J_{u_{k+1}}\|.$$

Step 4. Show that $\lim_{k \rightarrow \infty} \|\nabla J_{u_k}\| = 0$.

Since the sequence $(J(u_k))_{k \geq 0}$ is decreasing and the functional J is coercive, the sequence $(u_k)_{k \geq 0}$ must be bounded. By hypothesis, the derivative dJ is of J is continuous, so it is uniformly continuous over compact subsets of \mathbb{R}^n ; here we are using the fact that \mathbb{R}^n is finite dimensional. Hence, we deduce that for every $\epsilon > 0$, there is some $\delta > 0$ such that if $\|u_k - u_{k+1}\| < \delta$ then

$$\|dJ_{u_k} - dJ_{u_{k+1}}\|_2 < \epsilon.$$

But by definition of the operator norm and using the Cauchy–Schwarz inequality

$$\begin{aligned}\|dJ_{u_k} - dJ_{u_{k+1}}\|_2 &= \sup_{\|w\|=1} |dJ_{u_k}(w) - dJ_{u_{k+1}}(w)| \\ &= \sup_{\|w\|=1} |\langle \nabla J_{u_k} - \nabla J_{u_{k+1}}, w \rangle| \\ &\leq \|\nabla J_{u_k} - \nabla J_{u_{k+1}}\|.\end{aligned}$$

But we also have

$$\begin{aligned}\|\nabla J_{u_k} - \nabla J_{u_{k+1}}\|^2 &= \langle \nabla J_{u_k} - \nabla J_{u_{k+1}}, \nabla J_{u_k} - \nabla J_{u_{k+1}} \rangle \\ &= dJ_{u_k}(\nabla J_{u_k} - \nabla J_{u_{k+1}}) - dJ_{u_{k+1}}(\nabla J_{u_k} - \nabla J_{u_{k+1}}) \\ &\leq \|dJ_{u_k} - dJ_{u_{k+1}}\|_2^2,\end{aligned}$$

and so

$$\|dJ_{u_k} - dJ_{u_{k+1}}\|_2 = \|\nabla J_{u_k} - \nabla J_{u_{k+1}}\|.$$

It follows that since

$$\lim_{k \rightarrow \infty} \|u_k - u_{k+1}\| = 0$$

then

$$\lim_{k \rightarrow \infty} \|\nabla J_{u_k} - \nabla J_{u_{k+1}}\| = \lim_{k \rightarrow \infty} \|dJ_{u_k} - dJ_{u_{k+1}}\|_2 = 0,$$

and using the fact that

$$\|\nabla J_{u_k}\| \leq \|\nabla J_{u_k} - \nabla J_{u_{k+1}}\|,$$

we obtain

$$\lim_{k \rightarrow \infty} \|\nabla J_{u_k}\| = 0.$$

Step 5. Finally we can prove the convergence of the sequence $(u_k)_{k \geq 0}$.

Since J is elliptic and since $\nabla J_u = 0$ (since u is the minimum of J over \mathbb{R}^n), we have

$$\begin{aligned}\alpha \|u_k - u\|^2 &\leq \langle \nabla J_{u_k} - \nabla J_u, u_k - u \rangle \\ &= \langle \nabla J_{u_k}, u_k - u \rangle \\ &\leq \|\nabla J_{u_k}\| \|u_k - u\|.\end{aligned}$$

Hence, we obtain

$$\|u_k - u\| \leq \frac{1}{\alpha} \|\nabla J_{u_k}\|, \tag{b}$$

and since we showed that

$$\lim_{k \rightarrow \infty} \|\nabla J_{u_k}\| = 0,$$

we see that the sequence $(u_k)_{k \geq 0}$ converges to the minimum u . \square

Remarks: As with the previous proposition, the assumption of finite dimensionality is crucial. The proof provides an *a priori* bound on the error $\|u_k - u\|$.

If J is a an elliptic quadratic functional

$$J(v) = \frac{1}{2} \langle Av, v \rangle - \langle b, v \rangle,$$

we can use the orthogonality of the descent directions ∇J_{u_k} and $\nabla J_{u_{k+1}}$ to compute ρ_k . Indeed, we have $\nabla J_v = Av - b$, so

$$0 = \langle \nabla J_{u_{k+1}}, \nabla J_{u_k} \rangle = \langle A(u_k - \rho_k(Au_k - b)) - b, Au_k - b \rangle,$$

which yields

$$\rho_k = \frac{\|w_k\|^2}{\langle Aw_k, w_k \rangle}, \quad \text{with } w_k = Au_k - b = \nabla J_{u_k}.$$

Consequently, a step of the iteration method takes the following form:

- (1) Compute the vector

$$w_k = Au_k - b.$$

- (2) Compute the scalar

$$\rho_k = \frac{\|w_k\|^2}{\langle Aw_k, w_k \rangle}.$$

- (3) Compute the next vector u_{k+1} by

$$u_{k+1} = u_k - \rho_k w_k.$$

This method is of particular interest when the computation of Aw for a given vector w is cheap, which is the case if A is sparse.

Example 49.1. For a particular illustration of this method, we turn to the example provided by Shewchuk, with $A = \begin{pmatrix} 3 & 2 \\ 2 & 6 \end{pmatrix}$ and $b = \begin{pmatrix} 2 \\ -8 \end{pmatrix}$, namely

$$\begin{aligned} J(x, y) &= \frac{1}{2} \begin{pmatrix} x & y \end{pmatrix} \begin{pmatrix} 3 & 2 \\ 2 & 6 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} - \begin{pmatrix} 2 & -8 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} \\ &= \frac{3}{2}x^2 + 2xy + 3y^2 - 2x + 8y. \end{aligned}$$

This quadratic ellipsoid, which is illustrated in Figure 49.2, has a unique minimum at $(2, -2)$. In order to find this minimum via the gradient descent with optimal step size

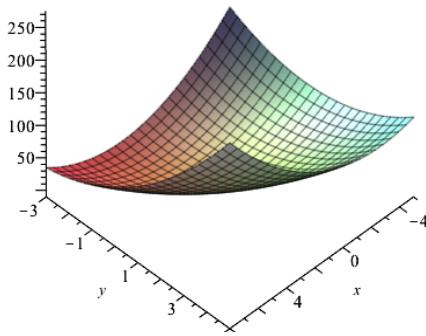

Figure 49.2: The ellipsoid $J(x, y) = \frac{3}{2}x^2 + 2xy + 3y^2 - 2x + 8y$.

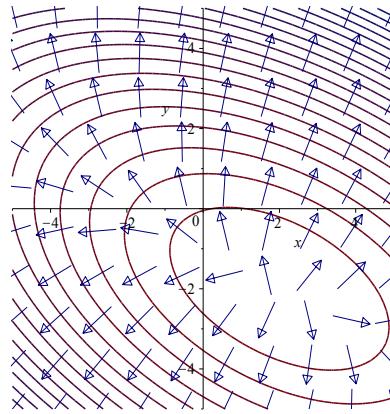

Figure 49.3: The level curves of $J(x, y) = \frac{3}{2}x^2 + 2xy + 3y^2 - 2x + 8y$ and the associated gradient vector field $\nabla J(x, y) = (3x + 2y - 2, 2x + 6y + 8)$.

parameter, we pick a starting point, say $u_k = (-2, -2)$, and calculate the search direction $w_k = \nabla J(-2, -2) = (-12, -8)$. Note that

$$\nabla J(x, y) = (3x + 2y - 2, 2x + 6y + 8) = \begin{pmatrix} 3 & 2 \\ 2 & 6 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} - \begin{pmatrix} 2 \\ -8 \end{pmatrix}$$

is perpendicular to the appropriate elliptical level curve; see Figure 49.3. We next perform the line search along the line given by the equation $-8x + 12y = -8$ and determine ρ_k . See Figures 49.4 and 49.5.

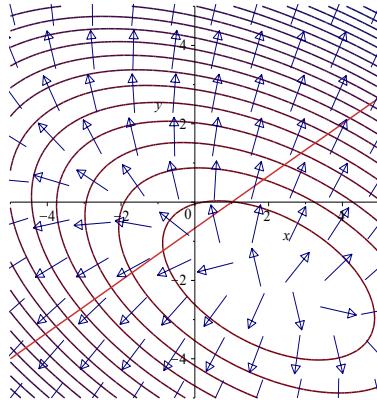

Figure 49.4: The level curves of $J(x, y) = \frac{3}{2}x^2 + 2xy + 3y^2 - 2x + 8y$ and the red search line with direction $\nabla J(-2, -2) = (-12, -8)$

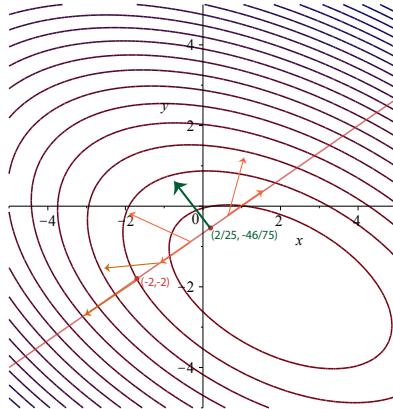

Figure 49.5: Let $u_k = (-2, -2)$. When traversing along the red search line, we look for the green perpendicular gradient vector. This gradient vector, which occurs at $u_{k+1} = (2/25, -46/75)$, provides a minimal ρ_k , since it has no nonzero projection on the search line.

In particular, we find that

$$\rho_k = \frac{\|w_k\|^2}{\langle Aw_k, w_k \rangle} = \frac{13}{75}.$$

This in turn gives us the new point

$$u_{k+1} = u_k - \frac{13}{75}w_k = (-2, -2) - \frac{13}{75}(-12, -8) = \left(\frac{2}{25}, -\frac{46}{75} \right),$$

and we continue the procedure by searching along the gradient direction $\nabla J(2/25, -46/75) = (-224/75, 112/25)$. Observe that $u_{k+1} = (\frac{2}{25}, -\frac{46}{75})$ has a gradient vector which is perpendicular to the search line with direction vector $w_k = \nabla J(-2, -2) = (-12, -8)$; see Figure

49.5. Geometrically this procedure corresponds to intersecting the plane $-8x + 12y = -8$ with the ellipsoid $J(x, y) = \frac{3}{2}x^2 + 2xy + 3y^2 - 2x + 8y$ to form the parabolic curve $f(x) = 25/6x^2 - 2/3x - 4$, and then locating the x -coordinate of its apex which occurs when $f'(x) = 0$, i.e when $x = 2/25$; see Figure 49.6. After 31 iterations, this procedure stabi-

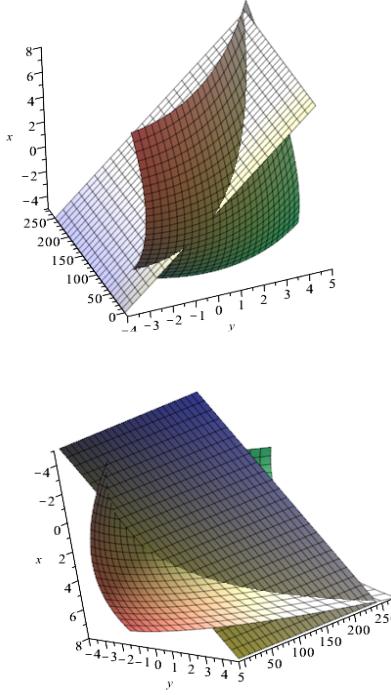

Figure 49.6: Two views of the intersection between the plane $-8x + 12y = -8$ and the ellipsoid $J(x, y) = \frac{3}{2}x^2 + 2xy + 3y^2 - 2x + 8y$. The point u_{k+1} is the minimum of the parabolic intersection.

lizes to point $(2, -2)$, which as we know, is the unique minimum of the quadratic ellipsoid $J(x, y) = \frac{3}{2}x^2 + 2xy + 3y^2 - 2x + 8y$.

A proof of the convergence of the gradient method with backtracking line search, under the hypothesis that J is strictly convex, is given in Boyd and Vandenberghe[29] (Section 9.3.1). More details on this method and the steepest descent method for the Euclidean norm can also be found in Boyd and Vandenberghe [29] (Section 9.3).

49.7 Convergence of Gradient Descent with Variable Stepsize

We now give a sufficient condition for the gradient method with variable stepsize parameter to converge. In addition to requiring J to be an elliptic functional, we add a Lipschitz

condition on the gradient of J . This time the space V can be infinite dimensional.

Proposition 49.14. *Let $J: V \rightarrow \mathbb{R}$ be a continuously differentiable functional defined on a Hilbert space V . Suppose there exists two constants $\alpha > 0$ and $M > 0$ such that*

$$\langle \nabla J_v - \nabla J_u, v - u \rangle \geq \alpha \|v - u\|^2 \quad \text{for all } u, v \in V,$$

and the Lipschitz condition

$$\|\nabla J_v - \nabla J_u\| \leq M \|v - u\| \quad \text{for all } u, v \in V.$$

If there exists two real numbers $a, b \in \mathbb{R}$ such that

$$0 < a \leq \rho_k \leq b \leq \frac{2\alpha}{M^2} \quad \text{for all } k \geq 0,$$

then the gradient method with variable stepsize parameter converges. Furthermore, there is some constant $\beta > 0$ (depending on α, M, a, b) such that

$$\beta < 1 \quad \text{and} \quad \|u_k - u\| \leq \beta^k \|u_0 - u\|,$$

where $u \in V$ is the unique minimum of J .

Proof. By hypothesis the functional J is elliptic, so by Theorem 49.8(2) it has a unique minimum u characterized by the fact that $\nabla J_u = 0$. Then since $u_{k+1} = u_k - \rho_k \nabla J_{u_k}$, we can write

$$u_{k+1} - u = (u_k - u) - \rho_k (\nabla J_{u_k} - \nabla J_u). \quad (*)$$

Using the inequalities

$$\langle \nabla J_{u_k} - \nabla J_u, u_k - u \rangle \geq \alpha \|u_k - u\|^2$$

and

$$\|\nabla J_{u_k} - \nabla J_u\| \leq M \|u_k - u\|,$$

and assuming that $\rho_k > 0$, it follows that

$$\begin{aligned} \|u_{k+1} - u\|^2 &= \|u_k - u\|^2 - 2\rho_k \langle \nabla J_{u_k} - \nabla J_u, u_k - u \rangle + \rho_k^2 \|\nabla J_{u_k} - \nabla J_u\|^2 \\ &\leq \left(1 - 2\alpha\rho_k + M^2\rho_k^2\right) \|u_k - u\|^2. \end{aligned}$$

Consider the function

$$T(\rho) = M^2\rho^2 - 2\alpha\rho + 1.$$

Its graph is a parabola intersecting the y -axis at $y = 1$ for $\rho = 0$, it has a minimum for $\rho = \alpha/M^2$, and it also has the value $y = 1$ for $\rho = 2\alpha/M^2$; see Figure 49.7. Therefore if we pick a, b and ρ_k such that

$$0 < a \leq \rho_k \leq b < \frac{2\alpha}{M^2},$$

we ensure that for $\rho \in [a, b]$ we have

$$T(\rho)^{1/2} = (M^2\rho^2 - 2\alpha\rho + 1)^{1/2} \leq (\max\{T(a), T(b)\})^{1/2} = \beta < 1.$$

Then by induction we get

$$\|u_{k+1} - u\| \leq \beta^{k+1} \|u_0 - u\|,$$

which proves convergence. \square

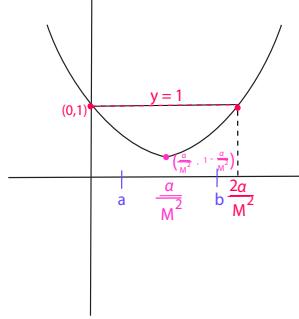

Figure 49.7: The parabola $T(\rho)$ used in the proof of Proposition 49.14.

Remarks: In the proof of Proposition 49.14, it is the fact that V is complete which plays a crucial role. If J is twice differentiable, the hypothesis

$$\|\nabla J_v - \nabla J_u\| \leq M \|v - u\| \quad \text{for all } u, v \in V$$

can be expressed as

$$\sup_{v \in V} \|\nabla^2 J_v\| \leq M.$$

In the case of a quadratic elliptic functional defined over \mathbb{R}^n ,

$$J(v) = \langle Av, v \rangle - \langle b, v \rangle,$$

the upper bound $2\alpha/M^2$ can be improved. In this case we have

$$\nabla J_v = Av - b,$$

and we know that $\alpha = \lambda_1$ and $M = \lambda_n$ do the job, where λ_1 is the smallest eigenvalue of A and λ_n is the largest eigenvalue of A . Hence we can pick a, b such that

$$0 < a \leq \rho_k \leq b < \frac{2\lambda_1}{\lambda_n^2}.$$

Since $u_{k+1} = u_k - \rho_k \nabla J_{u_k}$ and $\nabla J_{u_k} = Au_k - b$, we have

$$u_{k+1} - u = (u_k - u) - \rho_k(Au_k - Au) = (I - \rho_k A)(u_k - u),$$

so we get

$$\|u_{k+1} - u\| \leq \|I - \rho_k A\|_2 \|u_k - u\|.$$

However, since $I - \rho_k A$ is a symmetric matrix, $\|I - \rho_k A\|_2$ is the largest absolute value of its eigenvalues, so

$$\|I - \rho_k A\|_2 \leq \max\{|1 - \rho_k \lambda_1|, |1 - \rho_k \lambda_n|\}.$$

The function

$$\mu(\rho) = \max\{|1 - \rho \lambda_1|, |1 - \rho \lambda_n|\}$$

is a piecewise affine function, and it is easy to see that if we pick a, b such that

$$0 < a \leq \rho_k \leq b < \frac{2}{\lambda_n},$$

then

$$\max_{\rho \in [a, b]} \mu(\rho) \leq \max\{\mu(a), \mu(b)\} < 1.$$

Therefore, the upper bound $2\lambda_1/\lambda_n^2$ can be replaced by $2/\lambda_n$, which is typically much larger. A “good” pick for ρ_k is $2/(\lambda_1 + \lambda_n)$ (as opposed to λ_1/λ_n^2 for the first version). In this case

$$|1 - \rho_k \lambda_1| = |1 - \rho_k \lambda_n| = \frac{\lambda_n - \lambda_1}{\lambda_n + \lambda_1},$$

so we get

$$\beta = \frac{\lambda_n - \lambda_1}{\lambda_n + \lambda_1} = \frac{\frac{\lambda_n}{\lambda_1} - 1}{\frac{\lambda_n}{\lambda_1} + 1} = \frac{\text{cond}_2(A) - 1}{\text{cond}_2(A) + 1},$$

where $\text{cond}_2(A) = \lambda_n/\lambda_1$ is the condition number of the matrix A with respect to the spectral norm. Thus we see that the larger the condition number of A is, the slower the convergence of the method will be. This is not surprising since we already know that linear systems involving ill-conditioned matrices (matrices with a large condition number) are problematic and prone to numerical instability. One way to deal with this problem is to use a method known as preconditioning.

We only described the most basic gradient descent methods. There are numerous variants, and we only mention a few of these methods.

The method of *scaling* consists in using $-\rho_k D_k \nabla J_{u_k}$ as descent direction, where D_k is some suitably chosen symmetric positive definite matrix.

In the *gradient method with extrapolation*, u_{k+1} is determined by

$$u_{k+1} = u_k - \rho_k \nabla J_{u_k} + \beta_k(u_k - u_{k-1}).$$

Another rule for choosing the stepsize is *Armijo's rule*.

These methods, and others, are discussed in detail in Berstekas [17].

Boyd and Vandenberghe discuss steepest descent methods for various types of norms besides the Euclidean norm; see Boyd and Vandenberghe [29] (Section 9.4). Here is brief summary.

49.8 Steepest Descent for an Arbitrary Norm

The idea is to make $\langle \nabla J_{u_k}, d_k \rangle$ as negative as possible. To make the question sensible, we have to limit the size of d_k or normalize by the length of d_k .

Let $\| \cdot \|$ be any norm on \mathbb{R}^n . Recall from Section 14.7 that the *dual norm* is defined by

$$\|y\|^D = \sup_{\substack{x \in \mathbb{R}^n \\ \|x\|=1}} |\langle x, y \rangle|.$$

Definition 49.8. A *normalized steepest descent direction* (with respect to the norm $\| \cdot \|$) is any unit vector $d_{\text{nsd},k}$ which achieves the minimum of the set of reals

$$\{\langle \nabla J_{u_k}, d \rangle \mid \|d\| = 1\}.$$

By definition, $\|d_{\text{nsd},k}\| = 1$.

A *unnormalized steepest descent direction* $d_{\text{sd},k}$ is defined as

$$d_{\text{sd},k} = \|\nabla J_{u_k}\|^D d_{\text{nsd},k}.$$

It can be shown that

$$\langle \nabla J_{u_k}, d_{\text{sd},k} \rangle = -(\|\nabla J_{u_k}\|^D)^2;$$

see Boyd and Vandenberghe [29] (Section 9.4).

The *steepest descent method* (with respect to the norm $\| \cdot \|$) consists of the following steps: Given a starting point $u_0 \in \text{dom}(J)$ do:

repeat

- (1) Compute the steepest descent direction $d_{\text{sd},k}$.
- (2) Line search. Perform an exact or backtracking line search to find ρ_k .
- (3) Update. $u_{k+1} = u_k + \rho_k d_{\text{sd},k}$.

until stopping criterion is satisfied.

If $\|\cdot\|$ is the ℓ^2 -norm, then we see immediately that $d_{\text{sd},k} = -\nabla J_{u_k}$, so in this case the method *coincides* with the steepest descent method for the Euclidean norm as defined at the beginning of Section 49.6 in (3) and (4).

If P is a symmetric positive definite matrix, it is easy to see that $\|z\|_P = (z^\top P z)^{1/2} = \|P^{1/2}z\|_2$ is a norm. Then it can be shown that the normalized steepest descent direction is

$$d_{\text{nsd},k} = -(\nabla J_{u_k}^\top P^{-1} \nabla J_{u_k})^{-1/2} P^{-1} \nabla J_{u_k},$$

the dual norm is $\|z\|^D = \|P^{-1/2}z\|_2$, and the steepest descent direction with respect to $\|\cdot\|_P$ is given by

$$d_{\text{sd},k} = -P^{-1} \nabla J_{u_k}.$$

A judicious choice for P can speed up the rate of convergence of the gradient descent method; see Boyd and Vandenberghe [29] (Section 9.4.1 and Section 9.4.4).

If $\|\cdot\|$ is the ℓ^1 -norm, then it can be shown that $d_{\text{nsd},k}$ is determined as follows: let i be any index for which $\|\nabla J_{u_k}\|_\infty = |(\nabla J_{u_k})_i|$. Then

$$d_{\text{nsd},k} = -\text{sign}\left(\frac{\partial J}{\partial x_i}(u_k)\right) e_i,$$

where e_i is the i th canonical basis vector, and

$$d_{\text{sd},k} = -\frac{\partial J}{\partial x_i}(u_k) e_i.$$

For more details, see Boyd and Vandenberghe [29] (Section 9.4.2 and Section 9.4.4). It is also shown in Boyd and Vandenberghe [29] (Section 9.4.3) that the steepest descent method converges for any norm $\|\cdot\|$ and any strictly convex function J .

One of the main goals in designing a gradient descent method is to ensure that the convergence factor is as small as possible, which means that the method converges as quickly as possible. Machine learning has been a catalyst for finding such methods. A method discussed in Strang [171] (Chapter VI, Section 4) consists in adding a *momentum term* to the gradient. In this method, u_{k+1} and d_{k+1} are determined by the following system of equations:

$$\begin{aligned} u_{k+1} &= u_k - \rho d_k \\ d_{k+1} - \nabla J_{u_{k+1}} &= \beta d_k. \end{aligned}$$

Of course the trick is to choose ρ and β in such a way that the convergence factor is as small as possible. If J is given by a quadratic functional, say $(1/2)u^\top A u - b^\top u$, then $\nabla J_{u_{k+1}} = Au_{k+1} - b$ so we obtain a linear system. It turns out that the rate of convergence of

the method is determined by the largest and the smallest eigenvalues of A . Strang discusses this issue in the case of a 2×2 matrix. Convergence is significantly accelerated.

Another method is known as *Nesterov acceleration*. In this method,

$$u_{k+1} = u_k + \beta(u_k - u_{k-1}) - \rho \nabla J_{u_k + \gamma(u_k - u_{k-1})},$$

where β, ρ, γ are parameters. For details, see Strang [171] (Chapter VI, Section 4).

Lax also discusses other methods in which the step ρ_k is chosen using roots of Chebyshev polynomials; see Lax [113], Chapter 17, Sections 2–4.

A variant of Newton's method described in Section 41.2 can be used to find the minimum of a function belonging to a certain class of strictly convex functions. This method is the special case of the case where the norm is induced by a symmetric positive definite matrix P , namely $P = \nabla^2 J(x)$, the Hessian of J at x .

49.9 Newton's Method For Finding a Minimum

If $J: \Omega \rightarrow \mathbb{R}$ is a convex function defined on some open subset Ω of \mathbb{R}^n which is twice differentiable and if its Hessian $\nabla^2 J(x)$ is symmetric positive definite for all $x \in \Omega$, then by Proposition 40.12(2), the function J is strictly convex. In this case, for any $x \in \Omega$, we have the quadratic norm induced by $P = \nabla^2 J(x)$ as defined in the previous section, given by

$$\|u\|_{\nabla^2 J(x)} = (u^\top \nabla^2 J(x) u)^{1/2}.$$

The steepest descent direction for this quadratic norm is given by

$$d_{\text{nt}} = -(\nabla^2 J(x))^{-1} \nabla J_x.$$

The norm of d_{nt} for the the quadratic norm defined by $\nabla^2 J(x)$ is given by

$$\begin{aligned} (d_{\text{nt}}^\top \nabla^2 J(x) d_{\text{nt}})^{1/2} &= ((-\nabla J_x)^\top (\nabla^2 J(x))^{-1} \nabla^2 J(x) (-(\nabla^2 J(x))^{-1} \nabla J_x))^{1/2} \\ &= ((\nabla J_x)^\top (\nabla^2 J(x))^{-1} \nabla J_x)^{1/2}. \end{aligned}$$

Definition 49.9. Given a function $J: \Omega \rightarrow \mathbb{R}$ as above, for any $x \in \Omega$, the *Newton step* d_{nt} is defined by

$$d_{\text{nt}} = -(\nabla^2 J(x))^{-1} \nabla J_x,$$

and the *Newton decrement* $\lambda(x)$ is defined by

$$\lambda(x) = ((\nabla J_x)^\top (\nabla^2 J(x))^{-1} \nabla J_x)^{1/2}.$$

Observe that

$$\langle \nabla J_x, d_{\text{nt}} \rangle = (\nabla J_x)^\top (-(\nabla^2 J(x))^{-1} \nabla J_x) = -\lambda(x)^2.$$

If $\nabla J_x \neq 0$, we have $\lambda(x) \neq 0$, so $\langle \nabla J_x, d_{\text{nt}} \rangle < 0$, and d_{nt} is indeed a descent direction. The number $\langle \nabla J_x, d_{\text{nt}} \rangle$ is the constant that shows up during a backtracking line search.

A nice feature of the Newton step and of the Newton decrement is that they are affine invariant. This means that if T is an invertible matrix and if we define g by $g(y) = J(Ty)$, if the Newton step associated with J is denoted by $d_{J,\text{nt}}$ and similarly the Newton step associated with g is denoted by $d_{g,\text{nt}}$, then it is shown in Boyd and Vandenberghe [29] (Section 9.5.1) that

$$d_{g,\text{nt}} = T^{-1}d_{J,\text{nt}},$$

and so

$$x + d_{J,\text{nt}} = T(y + d_{g,\text{nt}}).$$

A similar properties applies to the Newton decrement.

Newton's method consists of the following steps: Given a starting point $u_0 \in \text{dom}(J)$ and a tolerance $\epsilon > 0$ do:

repeat

- (1) Compute the Newton step and decrement
 $d_{\text{nt},k} = -(\nabla^2 J(u_k))^{-1}\nabla J_{u_k}$ and $\lambda(u_k)^2 = (\nabla J_{u_k})^\top(\nabla^2 J(u_k))^{-1}\nabla J_{u_k}$.
- (2) Stopping criterion. **quit** if $\lambda(u_k)^2/2 \leq \epsilon$.
- (3) Line Search. Perform an exact or backtracking line search to find ρ_k .
- (4) Update. $u_{k+1} = u_k + \rho_k d_{\text{nt},k}$.

Observe that this is essentially the descent procedure of Section 49.8 using the Newton step as search direction, except that the stopping criterion is checked just after computing the search direction, rather than after the update (a very minor difference).

The convergence of Newton's method is thoroughly analyzed in Boyd and Vandenberghe [29] (Section 9.5.3). This analysis is made under the following assumptions:

- (1) The function $J: \Omega \rightarrow \mathbb{R}$ is a convex function defined on some open subset Ω of \mathbb{R}^n which is twice differentiable and its Hessian $\nabla^2 J(x)$ is symmetric positive definite for all $x \in \Omega$. This implies that there are two constants $m > 0$ and $M > 0$ such that $mI \preceq \nabla^2 J(x) \preceq MI$ for all $x \in \Omega$, which means that the eigenvalues of $\nabla^2 J(x)$ belong to $[m, M]$.
- (2) The Hessian is Lipschitzian, which means that there is some $L \geq 0$ such that

$$\|\nabla^2 J(x) - \nabla^2 J(y)\|_2 \leq L \|x, y\|_2 \quad \text{for all } x, y \in \Omega.$$

It turns out that the iterations of Newton's method fall into two phases, depending whether $\|\nabla J_{u_k}\|_2 \geq \eta$ or $\|\nabla J_{u_k}\|_2 < \eta$, where η is a number which depends on m, L , and the constant α used in the backtracking line search, and $\eta \leq m^2/L$.

- (1) The first phase, called the *damped Newton phase*, occurs while $\|\nabla J_{u_k}\|_2 \geq \eta$. During this phase, the procedure can choose a step size $\rho_k = t < 1$, and there is some constant $\gamma > 0$ such that

$$J(u_{k+1}) - J(u_k) \leq -\gamma.$$

- (2) The second phase, called the *quadratically convergent phase* or *pure Newton phase*, occurs while $\|\nabla J_{u_k}\|_2 < \eta$. During this phase, the step size $\rho_k = t = 1$ is always chosen, and we have

$$\frac{L}{2m^2} \|\nabla J_{u_{k+1}}\|_2 \leq \left(\frac{L}{2m^2} \|\nabla J_{u_k}\|_2 \right)^2. \quad (*_1)$$

If we denote the minimal value of f by p^* , then the number of damped Newton steps is at most

$$\frac{J(u_0) - p^*}{\gamma}.$$

Equation $(*_1)$ and the fact that $\eta \leq m^2/L$ shows that if $\|\nabla J_{u_k}\|_2 < \eta$, then $\|\nabla J_{u_{k+1}}\|_2 < \eta$. It follows by induction that for all $\ell \geq k$, we have

$$\frac{L}{2m^2} \|\nabla J_{u_{\ell+1}}\|_2 \leq \left(\frac{L}{2m^2} \|\nabla J_{u_\ell}\|_2 \right)^2, \quad (*_2)$$

and thus (since $\eta \leq m^2/L$ and $\|\nabla J_{u_k}\|_2 < \eta$, we have $(L/m^2) \|\nabla J_{u_k}\|_2 < (L/m^2)\eta \leq 1$), so

$$\frac{L}{2m^2} \|\nabla J_{u_\ell}\|_2 \leq \left(\frac{L}{2m^2} \|\nabla J_{u_k}\|_2 \right)^{2^{\ell-k}} \leq \left(\frac{1}{2} \right)^{2^{\ell-k}}, \quad \ell \geq k. \quad (*_3)$$

It is shown in Boyd and Vandenberghe [29] (Section 9.1.2) that the hypothesis $mI \preceq \nabla^2 J(x)$ implies that

$$J(x) - p^* \leq \frac{1}{2m} \|\nabla J_x\|_2^2 \quad x \in \Omega.$$

As a consequence, by $(*_3)$, we have

$$J(u_\ell) - p^* \leq \frac{1}{2m} \|\nabla J_{u_\ell}\|_2^2 \leq \frac{2m^3}{L^2} \left(\frac{1}{2} \right)^{2^{\ell-k}+1}. \quad (*_4)$$

Equation $(*_4)$ shows that the convergence during the quadratically convergence phase is very fast. If we let

$$\epsilon_0 = \frac{2m^3}{L^2},$$

then Equation $(*_4)$ implies that we must have $J(u_\ell) - p^* \leq \epsilon$ after no more than

$$\log_2 \log_2(\epsilon_0/\epsilon)$$

iterations. The term $\log_2 \log_2(\epsilon_0/\epsilon)$ grows *extremely slowly* as ϵ goes to zero, and for practical purposes it can be considered constant, say five or six (six iterations gives an accuracy of about $\epsilon \approx 5 \cdot 10^{-20} \epsilon_0$).

In summary, the number of Newton iterations required to find a minimum of J is approximately bounded by

$$\frac{J(u_0) - p^*}{\gamma} + 6.$$

Examples of the application of Newton's method and further discussion of its efficiency are given in Boyd and Vandenberghe [29] (Section 9.5.4). Basically, Newton's method has a faster convergence rate than gradient or steepest descent. Its main disadvantage is the cost for forming and storing the Hessian, and of computing the Newton step, which requires solving a linear system.

There are two major shortcomings of the convergence analysis of Newton's method as sketched above. The first is a practical one. The complexity estimates involve the constants m, M , and L , which are almost never known in practice. As a result, the bound on the number of steps required is almost never known specifically.

The second shortcoming is that although Newton's method itself is affine invariant, the analysis of convergence is very much dependent on the choice of coordinate system. If the coordinate system is changed, the constants m, M, L also change. This can be viewed as an aesthetic problem, but it would be nice if an analysis of convergence independent of an affine change of coordinates could be given.

Nesterov and Nemirovski discovered a condition on functions that allows an affine-invariant convergence analysis. This property, called *self-concordance*, is unfortunately not very intuitive.

Definition 49.10. A (partial) convex function f defined on \mathbb{R} is *self-concordant* if

$$|f'''(x)| \leq 2(f''(x))^{3/2} \quad \text{for all } x \in \mathbb{R}.$$

A (partial) convex function f defined on \mathbb{R}^n is *self-concordant* if for every nonzero $v \in \mathbb{R}^n$ and all $x \in \mathbb{R}^n$, the function $t \mapsto J(x + tv)$ is self-concordant.

Affine and convex quadratic functions are obviously self-concordant, since $f''' = 0$. There are many more interesting self-concordant functions, for example, the function $X \mapsto -\log \det(X)$, where X is a symmetric positive definite matrix.

Self-concordance is discussed extensively in Boyd and Vandenberghe [29] (Section 9.6). The main point of self-concordance is that a coordinate system-invariant proof of convergence can be given for a certain class of strictly convex self-concordant functions. This proof is given in Boyd and Vandenberghe [29] (Section 9.6.4). Given a starting value u_0 , we assume that the sublevel set $\{x \in \mathbb{R}^n \mid J(x) \leq J(u_0)\}$ is closed and that J is bounded below. Then there are two parameters η and γ as before, but *depending only on the parameters α, β involved in the line search*, such that:

(1) If $\lambda(u_k) > \eta$, then

$$J(u_{k+1}) - J(u_k) \leq -\gamma.$$

(2) If $\lambda(u_k) \leq \eta$, then the backtracking line search selects $t = 1$ and we have

$$2\lambda(u_{k+1}) \leq (2\lambda(u_k))^2.$$

As a consequence, for all $\ell \geq k$, we have

$$J(u_\ell) - p^* \leq \lambda(u_\ell)^2 \leq \left(\frac{1}{2}\right)^{2^{\ell-k+1}}.$$

In the end, accuracy $\epsilon > 0$ is achieved in at most

$$\frac{20 - 8\alpha}{\alpha\beta(1 - 2\alpha)^2}(J(u_0) - p^*) + \log_2 \log_2(1/\epsilon)$$

iterations, where α and β are the constants involved in the line search. This bound is obviously independent of the chosen coordinate system.

Contrary to intuition, the descent direction $d_k = -\nabla J_{u_k}$ given by the opposite of the gradient is *not* always optimal. In the next section we will see how a better direction can be picked; this is the method of *conjugate gradients*.

49.10 Conjugate Gradient Methods for Unconstrained Problems

The conjugate gradient method due to Hestenes and Stiefel (1952) is a gradient descent method that applies to an elliptic quadratic functional $J: \mathbb{R}^n \rightarrow \mathbb{R}$ given by

$$J(v) = \frac{1}{2}\langle Av, v\rangle - \langle b, v\rangle,$$

where A is an $n \times n$ symmetric positive definite matrix. Although it is presented as an iterative method, it terminates in at most n steps.

As usual, the conjugate gradient method starts with some arbitrary initial vector u_0 and proceeds through a sequence of iteration steps generating (better and better) approximations u_k of the optimal vector u minimizing J . During an iteration step, two vectors need to be determined:

(1) The descent direction d_k .

(2) The next approximation u_{k+1} . To find u_{k+1} , we need to find the stepsize $\rho_k > 0$ and then

$$u_{k+1} = u_k - \rho_k d_k.$$

Typically, ρ_k is found by performing a line search along the direction d_k , namely we find ρ_k as the real number such that the function $\rho \mapsto J(u_k - \rho d_k)$ is minimized.

We saw in Proposition 49.13 that during execution of the gradient method with optimal stepsize parameter that any two consecutive descent directions are orthogonal. The new twist with the conjugate gradient method is that given u_0, u_1, \dots, u_k , the next approximation u_{k+1} is obtained as the solution of the problem which consists in minimizing J over the affine subspace $u_k + \mathcal{G}_k$, where \mathcal{G}_k is the subspace of \mathbb{R}^n spanned by the gradients

$$\nabla J_{u_0}, \nabla J_{u_1}, \dots, \nabla J_{u_k}.$$

We may assume that $\nabla J_{u_\ell} \neq 0$ for $\ell = 0, \dots, k$, since the method terminates as soon as $\nabla J_{u_k} = 0$. A priori the subspace \mathcal{G}_k has dimension $\leq k+1$, but we will see that in fact it has dimension $k+1$. Then we have

$$u_k + \mathcal{G}_k = \left\{ u_k + \sum_{i=0}^k \alpha_i \nabla J_{u_i} \mid \alpha_i \in \mathbb{R}, 0 \leq i \leq k \right\},$$

and our minimization problem is to find u_{k+1} such that

$$u_{k+1} \in u_k + \mathcal{G}_k \quad \text{and} \quad J(u_{k+1}) = \inf_{v \in u_k + \mathcal{G}_k} J(v).$$

In the gradient method with optimal stepsize parameter the descent direction d_k is proportional to the gradient ∇J_{u_k} , but in the conjugate gradient method, d_k is equal to ∇J_{u_k} corrected by some multiple of d_{k-1} .

The conjugate gradient method is superior to the gradient method with optimal stepsize parameter for the following reasons proved correct later:

- (a) The gradients ∇J_{u_i} and ∇J_{u_j} are orthogonal for all i, j with $0 \leq i \neq j \leq k$. This implies that if $\nabla J_{u_i} \neq 0$ for $i = 0, \dots, k$, then the vectors ∇J_{u_i} are linearly independent, so the method stops in at most n steps.
- (b) If we write $\Delta_\ell = u_{\ell+1} - u_\ell = -\rho_\ell d_\ell$, the second remarkable fact about the conjugate gradient method is that the vectors Δ_ℓ satisfy the following conditions:

$$\langle A\Delta_\ell, \Delta_i \rangle = 0 \quad 0 \leq i < \ell \leq k.$$

The vectors Δ_ℓ and Δ_i are said to be *conjugate* with respect to the matrix A (or *A -conjugate*). As a consequence, if $\Delta_\ell \neq 0$ for $\ell = 0, \dots, k$, then the vectors Δ_ℓ are linearly independent.

- (c) There is a simple formula to compute d_{k+1} from d_k , and to compute ρ_k .

We now prove the above facts. We begin with (a).

Proposition 49.15. *Assume that $\nabla J_{u_i} \neq 0$ for $i = 0, \dots, k$. Then the minimization problem, find u_{k+1} such that*

$$u_{k+1} \in u_k + \mathcal{G}_k \quad \text{and} \quad J(u_{k+1}) = \inf_{v \in u_k + \mathcal{G}_k} J(v),$$

has a unique solution, and the gradients ∇J_{u_i} and ∇J_{u_j} are orthogonal for all i, j with $0 \leq i \neq j \leq k+1$.

Proof. The affine space $u_\ell + \mathcal{G}_\ell$ is closed and convex, and since J is a quadratic elliptic functional it is coercive and strictly convex, so by Theorem 49.8(2) it has a unique minimum in $u_\ell + \mathcal{G}_\ell$. This minimum $u_{\ell+1}$ is also the minimum of the problem, find $u_{\ell+1}$ such that

$$u_{\ell+1} \in u_\ell + \mathcal{G}_\ell \quad \text{and} \quad J(u_{\ell+1}) = \inf_{v \in \mathcal{G}_\ell} J(u_\ell + v),$$

and since \mathcal{G}_ℓ is a subspace, by Corollary 40.10 we must have

$$dJ_{u_{\ell+1}}(w) = 0 \quad \text{for all } w \in \mathcal{G}_\ell,$$

that is

$$\langle \nabla J_{u_{\ell+1}}, w \rangle = 0 \quad \text{for all } w \in \mathcal{G}_\ell.$$

Since \mathcal{G}_ℓ is spanned by $(\nabla J_{u_0}, \nabla J_{u_1}, \dots, \nabla J_{u_\ell})$, we obtain

$$\langle \nabla J_{u_{\ell+1}}, \nabla J_{u_j} \rangle = 0, \quad 0 \leq j \leq \ell,$$

and since this holds for $\ell = 0, \dots, k$, we get

$$\langle \nabla J_{u_i}, \nabla J_{u_j} \rangle = 0, \quad 0 \leq i \neq j \leq k+1,$$

which shows the second part of the proposition. \square

As a corollary of Proposition 49.15, if $\nabla J_{u_i} \neq 0$ for $i = 0, \dots, k$, then the vectors ∇J_{u_i} are linearly independent and \mathcal{G}_k has dimension $k+1$. Therefore, the conjugate gradient method terminates in at most n steps. Here is an example of a problem for which the gradient descent with optimal stepsize parameter does not converge in a finite number of steps.

Example 49.2. Let $J: \mathbb{R}^2 \rightarrow \mathbb{R}$ be the function given by

$$J(v_1, v_2) = \frac{1}{2}(\alpha_1 v_1^2 + \alpha_2 v_2^2),$$

where $0 < \alpha_1 < \alpha_2$. The minimum of J is attained at $(0, 0)$. Unless the initial vector $u_0 = (u_1^0, u_2^0)$ has the property that either $u_1^0 = 0$ or $u_2^0 = 0$, we claim that the gradient descent with optimal stepsize parameter does not converge in a finite number of steps. Observe that

$$\nabla J_{(v_1, v_2)} = \begin{pmatrix} \alpha_1 v_1 \\ \alpha_2 v_2 \end{pmatrix}.$$

As a consequence, given u_k , the line search for finding ρ_k and u_{k+1} yields $u_{k+1} = (0, 0)$ iff there is some $\rho \in \mathbb{R}$ such that

$$u_1^k = \rho \alpha_1 u_1^k \quad \text{and} \quad u_2^k = \rho \alpha_2 u_2^k.$$

Since $\alpha_1 \neq \alpha_2$, this is only possible if either $u_1^k = 0$ or $u_2^k = 0$. The formulae given just before Proposition 49.14 yield

$$u_1^{k+1} = \frac{\alpha_2^2(\alpha_2 - \alpha_1)u_1^k(u_2^k)^2}{\alpha_1^3(u_1^k)^2 + \alpha_2^3(u_2^k)^2}, \quad u_2^{k+1} = \frac{\alpha_1^2(\alpha_1 - \alpha_2)u_2^k(u_1^k)^2}{\alpha_1^3(u_1^k)^2 + \alpha_2^3(u_2^k)^2},$$

which implies that if $u_1^k \neq 0$ and $u_2^k \neq 0$, then $u_1^{k+1} \neq 0$ and $u_2^{k+1} \neq 0$, so the method runs forever from any initial vector $u_0 = (u_1^0, u_2^0)$ such that $u_1^0 \neq 0$ and, $u_2^0 \neq 0$.

We now prove (b).

Proposition 49.16. *Assume that $\nabla J_{u_i} \neq 0$ for $i = 0, \dots, k$, and let $\Delta_\ell = u_{\ell+1} - u_\ell$, for $\ell = 0, \dots, k$. Then $\Delta_\ell \neq 0$ for $\ell = 0, \dots, k$, and*

$$\langle A\Delta_\ell, \Delta_i \rangle = 0, \quad 0 \leq i < \ell \leq k.$$

The vectors $\Delta_0, \dots, \Delta_k$ are linearly independent.

Proof. Since J is a quadratic functional we have

$$\nabla J_{v+w} = A(v+w) - b = Av - b + Aw = \nabla J_v + Aw.$$

It follows that

$$\nabla J_{u_{\ell+1}} = \nabla J_{u_\ell + \Delta_\ell} = \nabla J_{u_\ell} + A\Delta_\ell, \quad 0 \leq \ell \leq k. \quad (*_1)$$

By Proposition 49.15, since

$$\langle \nabla J_{u_i}, \nabla J_{u_j} \rangle = 0, \quad 0 \leq i \neq j \leq k,$$

we get

$$0 = \langle \nabla J_{u_{\ell+1}}, \nabla J_{u_\ell} \rangle = \|\nabla J_{u_\ell}\|^2 + \langle A\Delta_\ell, \nabla J_{u_\ell} \rangle, \quad \ell = 0, \dots, k,$$

and since by hypothesis $\nabla J_{u_i} \neq 0$ for $i = 0, \dots, k$, we deduce that

$$\Delta_\ell \neq 0, \quad \ell = 0, \dots, k.$$

If $k \geq 1$, for $i = 0, \dots, \ell - 1$ and $\ell \leq k$ we also have

$$\begin{aligned} 0 &= \langle \nabla J_{u_{\ell+1}}, \nabla J_{u_i} \rangle = \langle \nabla J_{u_\ell}, \nabla J_{u_i} \rangle + \langle A\Delta_\ell, \nabla J_{u_i} \rangle \\ &= \langle A\Delta_\ell, \nabla J_{u_i} \rangle. \end{aligned}$$

Since $\Delta_j = u_{j+1} - u_j \in \mathcal{G}_j$ and \mathcal{G}_j is spanned by $(\nabla J_{u_0}, \nabla J_{u_1}, \dots, \nabla J_{u_j})$, we obtain

$$\langle A\Delta_\ell, \Delta_j \rangle = 0, \quad 0 \leq j < \ell \leq k.$$

For the last statement of the proposition, let w_0, w_1, \dots, w_k be any $k+1$ nonzero vectors such that

$$\langle Aw_i, w_j \rangle = 0, \quad 0 \leq i < j \leq k.$$

We claim that w_0, w_1, \dots, w_k are linearly independent.

If we have a linear dependence $\sum_{i=0}^k \lambda_i w_i = 0$, then we have

$$0 = \left\langle A \left(\sum_{i=0}^k \lambda_i w_i \right), w_j \right\rangle = \sum_{i=0}^k \lambda_i \langle Aw_i, w_j \rangle = \lambda_j \langle Aw_j, w_j \rangle,$$

where we form these inner products for $j = 0, \dots, k$, in that order. Since A is symmetric positive definite (because J is a quadratic elliptic functional) and $w_j \neq 0$, we have $\langle Aw_j, w_j \rangle > 0$, and so $\lambda_j = 0$ for $j = 0, \dots, k$. Therefore the vectors w_0, w_1, \dots, w_k are linearly independent. \square

Remarks:

- (1) Since A is symmetric positive definite, the bilinear map $(u, v) \mapsto \langle Au, v \rangle$ is an inner product $\langle -, - \rangle_A$ on \mathbb{R}^n . Consequently, two vectors u, v are *conjugate* with respect to the matrix A (or A -*conjugate*), which means that $\langle Au, v \rangle = 0$, iff u and v are orthogonal with respect to the inner product $\langle -, - \rangle_A$.
- (2) By picking the descent direction to be $-\nabla J_{u_k}$, the gradient descent method with optimal stepsize parameter treats the level sets $\{u \mid J(u) = J(u_k)\}$ as if they were spheres. The conjugate gradient method is more subtle, and takes the “geometry” of the level set $\{u \mid J(u) = J(u_k)\}$ into account, through the notion of conjugate directions.
- (3) The notion of conjugate direction has its origins in the theory of projective conics and quadrics where A is a 2×2 or a 3×3 matrix and where u and v are conjugate iff $u^\top A v = 0$.
- (4) The terminology conjugate gradient is somewhat misleading. It is not the gradients who are conjugate directions, but the descent directions.

By definition of the vectors $\Delta_\ell = u_{\ell+1} - u_\ell$, we can write

$$\Delta_\ell = \sum_{i=0}^{\ell} \delta_i^\ell \nabla J_{u_i}, \quad 0 \leq \ell \leq k. \quad (*_2)$$

In matrix form, we can write

$$(\Delta_0 \quad \Delta_1 \quad \cdots \quad \Delta_k) = (\nabla J_{u_0} \quad \nabla J_{u_1} \quad \cdots \quad \nabla J_{u_k}) \begin{pmatrix} \delta_0^0 & \delta_0^1 & \cdots & \delta_0^{k-1} & \delta_0^k \\ 0 & \delta_1^1 & \cdots & \delta_1^{k-1} & \delta_1^k \\ 0 & 0 & \cdots & \delta_2^{k-1} & \delta_2^k \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & 0 & \delta_k^k \end{pmatrix},$$

which implies that $\delta_\ell^\ell \neq 0$ for $\ell = 0, \dots, k$.

In view of the above fact, since Δ_ℓ and d_ℓ are collinear, it is convenient to write the descent direction d_ℓ as

$$d_\ell = \sum_{i=0}^{\ell-1} \lambda_i^\ell \nabla J_{u_i} + \nabla J_{u_\ell}, \quad 0 \leq \ell \leq k. \quad (*_3)$$

Our next goal is to compute u_{k+1} , assuming that the coefficients λ_i^k are known for $i = 0, \dots, k$, and then to find simple formulae for the λ_i^k .

The problem reduces to finding ρ_k such that

$$J(u_k - \rho_k d_k) = \inf_{\rho \in \mathbb{R}} J(u_k - \rho d_k),$$

and then $u_{k+1} = u_k - \rho_k d_k$. In fact, by $(*_2)$, since

$$\Delta_k = \sum_{i=0}^k \delta_i^k \nabla J_{u_i} = \delta_k^k \left(\sum_{i=0}^{k-1} \frac{\delta_i^k}{\delta_k^k} \nabla J_{u_i} + \nabla J_{u_k} \right),$$

we must have

$$\Delta_k = \delta_k^k d_k \quad \text{and} \quad \rho_k = -\delta_k^k. \quad (*_4)$$

Remarkably, the coefficients λ_i^k and the descent directions d_k can be computed easily using the following formulae.

Proposition 49.17. *Assume that $\nabla J_{u_i} \neq 0$ for $i = 0, \dots, k$. If we write*

$$d_\ell = \sum_{i=0}^{\ell-1} \lambda_i^\ell \nabla J_{u_i} + \nabla J_{u_\ell}, \quad 0 \leq \ell \leq k,$$

then we have

$$(\dagger) \quad \begin{cases} \lambda_i^k = \frac{\|\nabla J_{u_k}\|^2}{\|\nabla J_{u_i}\|^2}, & 0 \leq i \leq k-1, \\ d_0 = \nabla J_{u_0} \\ d_\ell = \nabla J_{u_\ell} + \frac{\|\nabla J_{u_\ell}\|^2}{\|\nabla J_{u_{\ell-1}}\|^2} d_{\ell-1}, & 1 \leq \ell \leq k. \end{cases}$$

Proof. Since by $(*_4)$ we have $\Delta_k = \delta_k^k d_k$, $\delta_k^k \neq 0$, (by Proposition 49.16) we have

$$\langle A d_\ell, \Delta_i \rangle = 0, \quad 0 \leq i < \ell \leq k.$$

By $(*_1)$ we have $\nabla J_{u_{\ell+1}} = \nabla J_{u_\ell} + A \Delta_\ell$, and since A is a symmetric matrix, we have

$$0 = \langle A d_k, \Delta_\ell \rangle = \langle d_k, A \Delta_\ell \rangle = \langle d_k, \nabla J_{u_{\ell+1}} - \nabla J_{u_\ell} \rangle,$$

for $\ell = 0, \dots, k-1$. Since

$$d_k = \sum_{i=0}^{k-1} \lambda_i^k \nabla J_{u_i} + \nabla J_{u_k},$$

we have

$$\left\langle \sum_{i=0}^{k-1} \lambda_i^k \nabla J_{u_i} + \nabla J_{u_k}, \nabla J_{u_{\ell+1}} - \nabla J_{u_\ell} \right\rangle = 0, \quad 0 \leq \ell \leq k-1.$$

Since by Proposition 49.15 the gradients ∇J_{u_i} are pairwise orthogonal, the above equations yield

$$\begin{aligned} -\lambda_{k-1}^k \|\nabla J_{u_{k-1}}\|^2 + \|\nabla J_{u_k}\|^2 &= 0 \\ -\lambda_\ell^k \|\nabla J_{u_\ell}\|^2 + \lambda_{\ell+1}^k \|\nabla J_{u_{\ell+1}}\|^2 &= 0, \quad 0 \leq \ell \leq k-2, \quad k \geq 2, \end{aligned}$$

and an easy induction yields

$$\lambda_i^k = \frac{\|\nabla J_{u_k}\|^2}{\|\nabla J_{u_i}\|^2}, \quad 0 \leq i \leq k-1.$$

Consequently, using $(*_3)$ we have

$$\begin{aligned} d_k &= \sum_{i=0}^{k-1} \frac{\|\nabla J_{u_k}\|^2}{\|\nabla J_{u_i}\|^2} \nabla J_{u_i} + \nabla J_{u_k} \\ &= \nabla J_{u_k} + \frac{\|\nabla J_{u_k}\|^2}{\|\nabla J_{u_{k-1}}\|^2} \left(\sum_{i=0}^{k-2} \frac{\|\nabla J_{u_{k-1}}\|^2}{\|\nabla J_{u_i}\|^2} \nabla J_{u_i} + \nabla J_{u_{k-1}} \right) \\ &= \nabla J_{u_k} + \frac{\|\nabla J_{u_k}\|^2}{\|\nabla J_{u_{k-1}}\|^2} d_{k-1}, \end{aligned}$$

which concludes the proof. \square

It remains to compute ρ_k , which is the solution of the line search

$$J(u_k - \rho_k d_k) = \inf_{\rho \in \mathbb{R}} J(u_k - \rho d_k).$$

Since J is a quadratic functional, a basic computation left to the reader shows that the function to be minimized is

$$\rho \mapsto \frac{\rho^2}{2} \langle Ad_k, d_k \rangle - \rho \langle \nabla J_{u_k}, d_k \rangle + J(u_k),$$

whose minimum is obtained when its derivative is zero, that is,

$$\rho_k = \frac{\langle \nabla J_{u_k}, d_k \rangle}{\langle Ad_k, d_k \rangle}. \quad (*_5)$$

In summary, the conjugate gradient method finds the minimum u of the elliptic quadratic functional

$$J(v) = \frac{1}{2} \langle Av, v \rangle - \langle b, v \rangle$$

by computing the sequence of vectors $u_1, d_1, \dots, u_{k-1}, d_{k-1}, u_k$, starting from any vector u_0 , with

$$d_0 = \nabla J_{u_0}.$$

If $\nabla J_{u_0} = 0$, then the algorithm terminates with $u = u_0$. Otherwise, for $k \geq 0$, assuming that $\nabla J_{u_i} \neq 0$ for $i = 1, \dots, k$, compute

$$(*_6) \quad \begin{cases} \rho_k = \frac{\langle \nabla J_{u_k}, d_k \rangle}{\langle Ad_k, d_k \rangle} \\ u_{k+1} = u_k - \rho_k d_k \\ d_{k+1} = \nabla J_{u_{k+1}} + \frac{\|\nabla J_{u_{k+1}}\|^2}{\|\nabla J_{u_k}\|^2} d_k. \end{cases}$$

If $\nabla J_{u_{k+1}} = 0$, then the algorithm terminates with $u = u_{k+1}$.

As we showed before, the algorithm terminates in at most n iterations.

Example 49.3. Let us take the example of Section 49.6 and apply the conjugate gradient procedure. Recall that

$$\begin{aligned} J(x, y) &= \frac{1}{2} \begin{pmatrix} x & y \end{pmatrix} \begin{pmatrix} 3 & 2 \\ 2 & 6 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} - \begin{pmatrix} 2 & -8 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} \\ &= \frac{3}{2}x^2 + 2xy + 3y^2 - 2x + 8y. \end{aligned}$$

Note that $\nabla J_v = (3x + 2y - 2, 2x + 6y + 8)$,

Initialize the procedure by setting

$$u_0 = (-2, -2), \quad d_0 = \nabla J_{u_0} = (-12, -8)$$

Step 1 involves calculating

$$\begin{aligned} \rho_0 &= \frac{\langle \nabla J_{u_0}, d_0 \rangle}{\langle Ad_0, d_0 \rangle} = \frac{13}{75} \\ u_1 &= u_0 - \rho_0 d_0 = (-2, -2) - \frac{13}{75}(-12, -8) = \left(\frac{2}{25}, -\frac{46}{75} \right) \\ d_1 &= \nabla J_{u_1} + \frac{\|\nabla J_{u_1}\|^2}{\|\nabla J_{u_0}\|^2} d_0 = \left(-\frac{2912}{625}, \frac{18928}{5625} \right). \end{aligned}$$

Observe that ρ_0 and u_1 are precisely the *same* as in the case the case of gradient descent with optimal step size parameter. The difference lies in the calculation of d_1 . As we will see, this change will make a *huge* difference in the convergence to the unique minimum $u = (2, -2)$.

We continue with the conjugate gradient procedure and calculate Step 2 as

$$\begin{aligned} \rho_1 &= \frac{\langle \nabla J_{u_1}, d_1 \rangle}{\langle Ad_1, d_1 \rangle} = \frac{75}{82} \\ u_2 &= u_1 - \rho_1 d_1 = \left(\frac{2}{25}, -\frac{46}{75} \right) - \frac{75}{82} \left(-\frac{2912}{625}, \frac{18928}{5625} \right) = (2, -2) \\ d_2 &= \nabla J_{u_2} + \frac{\|\nabla J_{u_2}\|^2}{\|\nabla J_{u_1}\|^2} d_1 = (0, 0). \end{aligned}$$

Since $\nabla J_{u_2} = 0$, the procedure terminates in *two* steps, as opposed to the 31 steps needed for gradient descent with optimal step size parameter.

Hestenes and Stiefel realized that Equations $(*_6)$ can be modified to make the computations more efficient, by having only one evaluation of the matrix A on a vector, namely d_k . The idea is to compute ∇_{u_k} inductively.

Since by $(*_1)$ and $(*_4)$ we have $\nabla J_{u_{\ell+1}} = \nabla J_{u_\ell} + A\Delta_\ell = \nabla J_{u_\ell} - \rho_\ell Ad_\ell$, the gradient $\nabla J_{u_{\ell+1}}$ can be computed iteratively:

$$\begin{aligned}\nabla J_0 &= Au_0 - b \\ \nabla J_{u_{\ell+1}} &= \nabla J_{u_\ell} - \rho_\ell Ad_\ell.\end{aligned}$$

Since by Proposition 49.17 we have

$$d_k = \nabla J_{u_k} + \frac{\|\nabla J_{u_k}\|^2}{\|\nabla J_{u_{k-1}}\|^2} d_{k-1}$$

and since d_{k-1} is a linear combination of the gradients ∇J_{u_i} for $i = 0, \dots, k-1$, which are all orthogonal to ∇J_{u_k} , we have

$$\rho_k = \frac{\langle \nabla J_{u_k}, d_k \rangle}{\langle Ad_k, d_k \rangle} = \frac{\|\nabla J_{u_k}\|^2}{\langle Ad_k, d_k \rangle}.$$

It is customary to introduce the term r_k defined as

$$r_k = \nabla J_{u_k} = Au_k - b \quad (*_7)$$

and to call it the *residual*. Then the conjugate gradient method consists of the following steps. We initialize the method starting from any vector u_0 and set

$$d_0 = r_0 = Au_0 - b.$$

The main iteration step is ($k \geq 0$):

$$(*_8) \quad \left\{ \begin{array}{l} \rho_k = \frac{\|r_k\|^2}{\langle Ad_k, d_k \rangle} \\ u_{k+1} = u_k - \rho_k d_k \\ r_{k+1} = r_k - \rho_k Ad_k \\ \beta_{k+1} = \frac{\|r_{k+1}\|^2}{\|r_k\|^2} \\ d_{k+1} = r_{k+1} + \beta_{k+1} d_k. \end{array} \right.$$

Beware that some authors define the residual r_k as $r_k = b - Au_k$ and the descent direction d_k as $-d_k$. In this case, the second equation becomes

$$u_{k+1} = u_k + \rho_k d_k.$$

Since $d_0 = r_0$, the equations

$$\begin{aligned}r_{k+1} &= r_k - \rho_k Ad_k \\ d_{k+1} &= r_{k+1} + \beta_{k+1} d_k\end{aligned}$$

imply by induction that the subspace \mathcal{G}_k is spanned by (r_0, r_1, \dots, r_k) and (d_0, d_1, \dots, d_k) is the subspace spanned by

$$(r_0, Ar_0, A^2r_0, \dots, A^kr_0).$$

Such a subspace is called a *Krylov subspace*.

If we define the *error* e_k as $e_k = u_k - u$, then $e_0 = u_0 - u$ and $Ae_0 = Au_0 - Au = Au_0 - b = d_0 = r_0$, and then because

$$u_{k+1} = u_k - \rho_k d_k$$

we see that

$$e_{k+1} = e_k - \rho_k d_k.$$

Since d_k belongs to the subspace spanned by $(r_0, Ar_0, A^2r_0, \dots, A^kr_0)$ and $r_0 = Ae_0$, we see that d_k belongs to the subspace spanned by $(Ae_0, A^2e_0, A^3e_0, \dots, A^{k+1}e_0)$, and then by induction we see that e_{k+1} belongs to the subspace spanned by $(e_0, Ae_0, A^2e_0, A^3e_0, \dots, A^{k+1}e_0)$. This means that there is a polynomial P_k of degree $\leq k$ such that $P_k(0) = 1$ and

$$e_k = P_k(A)e_0.$$

This is an important fact because it allows for an analysis of the convergence of the conjugate gradient method; see Trefethen and Bau [176] (Lecture 38). For this, since A is symmetric positive definite, we know that $\langle u, v \rangle_A = \langle Av, u \rangle$ is an inner product on \mathbb{R}^n whose associated norm is denoted by $\|v\|_A$. Then observe that if $e(v) = v - u$, then

$$\begin{aligned} \|e(v)\|_A^2 &= \langle Av - Au, v - u \rangle \\ &= \langle Av, v \rangle - 2\langle Au, v \rangle + \langle Au, u \rangle \\ &= \langle Av, v \rangle - 2\langle b, v \rangle + \langle b, u \rangle \\ &= 2J(v) + \langle b, u \rangle. \end{aligned}$$

It follows that $v = u_k$ minimizes $\|e(v)\|_A$ on $u_{k-1} + \mathcal{G}_{k-1}$ since u_k minimizes J on $u_{k-1} + \mathcal{G}_{k-1}$. Since $e_k = P_k(A)e_0$ for some polynomial P_k of degree $\leq k$ such that $P_k(0) = 1$, if we let \mathcal{P}_k be the set of polynomials $P(t)$ of degree $\leq k$ such that $P(0) = 1$, then we have

$$\|e_k\|_A = \inf_{P \in \mathcal{P}_k} \|P(A)e_0\|_A.$$

Since A is a symmetric positive definite matrix it has real positive eigenvalues $\lambda_1, \dots, \lambda_n$ and there is an orthonormal basis of eigenvectors h_1, \dots, h_n so that if we write $e_0 = \sum_{j=1}^n a_j h_j$, then we have

$$\|e_0\|_A^2 = \langle Ae_0, e_0 \rangle = \left\langle \sum_{i=1}^n a_i \lambda_i h_i, \sum_{j=1}^n a_j h_j \right\rangle = \sum_{j=1}^n a_j^2 \lambda_j$$

and

$$\|P(A)e_0\|_A^2 = \langle AP(A)e_0, P(A)e_0 \rangle = \left\langle \sum_{i=1}^n a_i \lambda_i P(\lambda_i) h_i, \sum_{j=1}^n a_j P(\lambda_j) h_j \right\rangle = \sum_{j=1}^n a_j^2 \lambda_j (P(\lambda_j))^2.$$

These equations imply that

$$\|e_k\|_A \leq \left(\inf_{P \in \mathcal{P}_k} \max_{1 \leq i \leq n} |P(\lambda_i)| \right) \|e_0\|_A.$$

It can be shown that the conjugate gradient method requires of the order of n^3 additions, n^3 multiplications, and $2n$ divisions.

In theory, this is worse than the number of elementary operations required by the Cholesky method. Even though the conjugate gradient method does not seem to be the best method for *full* matrices, it usually outperforms other methods for *sparse* matrices. The reason is that the matrix A only appears in the computation of the vector Ad_k . If the matrix A is banded (for example, tridiagonal), computing Ad_k is very cheap and there is no need to store the entire matrix A , in which case the conjugate gradient method is fast. Also, although in theory, up to n iterations may be required, in practice, convergence may occur after a much smaller number of iterations.

Using the inequality

$$\|e_k\|_A \leq \left(\inf_{P \in \mathcal{P}_k} \max_{1 \leq i \leq n} |P(\lambda_i)| \right) \|e_0\|_A,$$

by choosing P to be a shifted Chebyshev polynomial, it can be shown that

$$\|e_k\|_A \leq 2 \left(\frac{\sqrt{\kappa} - 1}{\sqrt{\kappa} + 1} \right)^k \|e_0\|_A,$$

where $\kappa = \text{cond}_2(A)$; see Trefethen and Bau [176] (Lecture 38, Theorem 38.5). Thus the rate of convergence of the conjugate gradient method is governed by the ratio

$$\frac{\sqrt{\text{cond}_2(A)} - 1}{\sqrt{\text{cond}_2(A)} + 1},$$

where $\text{cond}_2(A) = \lambda_n/\lambda_1$ is the condition number of the matrix A . Since A is positive definite, λ_1 is its smallest eigenvalue and λ_n is its largest eigenvalue.

The above fact leads to the process of *preconditioning*, a method which consists in replacing the matrix of a linear system $Ax = b$ by an “equivalent” one for example $M^{-1}A$ (since M is invertible, the system $Ax = b$ is equivalent to the system $M^{-1}Ax = M^{-1}b$), where M is chosen so that $M^{-1}A$ is still symmetric positive definite and has a smaller condition number than A ; see Trefethen and Bau [176] (Lecture 40) and Demmel [48] (Section 6.6.5).

The method of conjugate gradients can be generalized to functionals that are not necessarily quadratic. The stepsize parameter ρ_k is still determined by a line search which consists in finding ρ_k such that

$$J(u_k - \rho_k d_k) = \inf_{\rho \in \mathbb{R}} J(u_k - \rho d_k).$$

This is more difficult than in the quadratic case and in general there is no guarantee that ρ_k is unique, so some criterion to pick ρ_k is needed. Then

$$u_{k+1} = u_k - \rho_k d_k,$$

and the next descent direction can be chosen in two ways:

(1) (*Polak–Ribi  re*)

$$d_k = \nabla J_{u_k} + \frac{\langle \nabla J_{u_k}, \nabla J_{u_k} - \nabla J_{u_{k-1}} \rangle}{\|\nabla J_{u_{k-1}}\|^2} d_{k-1},$$

(2) (*Fletcher–Reeves*)

$$d_k = \nabla J_{u_k} + \frac{\|\nabla J_{u_k}\|^2}{\|\nabla J_{u_{k-1}}\|^2} d_{k-1}.$$

Consecutive gradients are no longer orthogonal so these methods may run forever. There are various sufficient criteria for convergence. In practice, the Polak–Ribi  re method converges faster. There is no longer any guarantee that these methods converge to a global minimum.

49.11 Gradient Projection Methods for Constrained Optimization

We now consider the problem of finding the minimum of a convex functional $J: V \rightarrow \mathbb{R}$ over a nonempty, convex, closed subset U of a Hilbert space V . By Theorem 40.13(3), the functional J has a minimum at $u \in U$ iff

$$dJ_u(v - u) \geq 0 \quad \text{for all } v \in U,$$

which can be expressed as

$$\langle \nabla J_u, v - u \rangle \geq 0 \quad \text{for all } v \in U.$$

On the other hand, by the projection lemma (Proposition 48.5), the condition for a vector $u \in U$ to be the projection of an element $w \in V$ onto U is

$$\langle u - w, v - u \rangle \geq 0 \quad \text{for all } v \in U.$$

These conditions are obviously analogous, and we can make this analogy more precise as follows. If $p_U: V \rightarrow U$ is the projection map onto U , we have the following chain of equivalences:

$$\begin{aligned} u \in U \quad \text{and} \quad J(u) = \inf_{v \in U} J(v) &\quad \text{iff} \\ u \in U \quad \text{and} \quad \langle \nabla J_u, v - u \rangle \geq 0 &\quad \text{for every } v \in U, \text{ iff} \\ u \in U \quad \text{and} \quad \langle u - (u - \rho \nabla J_u), v - u \rangle \geq 0 &\quad \text{for every } v \in U \text{ and every } \rho > 0, \text{ iff} \\ u = p_U(u - \rho \nabla J_u) &\quad \text{for every } \rho > 0. \end{aligned}$$

In other words, for every $\rho > 0$, $u \in V$ is a *fixed-point* of the function $g: V \rightarrow U$ given by

$$g(v) = p_U(v - \rho \nabla J_v).$$

The above suggests finding u by the method of successive approximations for finding the fixed-point of a contracting mapping, namely given any initial $u_0 \in V$, to define the sequence $(u_k)_{k \geq 0}$ such that

$$u_{k+1} = p_U(u_k - \rho_k \nabla J_{u_k}),$$

where the parameter $\rho_k > 0$ is chosen at each step. This method is called the *projected-gradient method with variable stepsize parameter*. Observe that if $U = V$, then this is just the gradient method with variable stepsize. We have the following result about the convergence of this method.

Proposition 49.18. *Let $J: V \rightarrow \mathbb{R}$ be a continuously differentiable functional defined on a Hilbert space V , and let U be nonempty, convex, closed subset of V . Suppose there exists two constants $\alpha > 0$ and $M > 0$ such that*

$$\langle \nabla J_v - \nabla J_u, v - u \rangle \geq \alpha \|v - u\|^2 \quad \text{for all } u, v \in V,$$

and

$$\|\nabla J_v - \nabla J_u\| \leq M \|v - u\| \quad \text{for all } u, v \in V.$$

If there exists two real numbers $a, b \in \mathbb{R}$ such that

$$0 < a \leq \rho_k \leq b \leq \frac{2\alpha}{M^2} \quad \text{for all } k \geq 0,$$

then the projected-gradient method with variable stepsize parameter converges. Furthermore, there is some constant $\beta > 0$ (depending on α, M, a, b) such that

$$\beta < 1 \quad \text{and} \quad \|u_k - u\| \leq \beta^k \|u_0 - u\|,$$

where $u \in M$ is the unique minimum of J .

Proof. For every $\rho_k \geq 0$, define the function $g_k: V \rightarrow U$ by

$$g_k(v) = p_U(v - \rho_k \nabla J_v).$$

By Proposition 48.6, the projection map p_U has Lipschitz constant 1, so using the inequalities assumed to hold in the proposition, we have

$$\begin{aligned} \|g_k(v_1) - g_k(v_2)\|^2 &= \|p_U(v_1 - \rho_k \nabla J_{v_1}) - p_U(v_2 - \rho_k \nabla J_{v_2})\|^2 \\ &\leq \|(v_1 - v_2) - \rho_k(\nabla J_{v_1} - \nabla J_{v_2})\|^2 \\ &= \|v_1 - v_2\|^2 - 2\rho_k \langle \nabla J_{v_1} - \nabla J_{v_2}, v_1 - v_2 \rangle + \rho_k^2 \|\nabla J_{v_1} - \nabla J_{v_2}\|^2 \\ &\leq \left(1 - 2\alpha\rho_k + M^2\rho_k^2\right) \|v_1 - v_2\|^2. \end{aligned}$$

As in the proof of Proposition 49.14, we know that if a and b satisfy the conditions $0 < a \leq \rho_k \leq b \leq \frac{2\alpha}{M^2}$, then there is some β such that

$$\left(1 - 2\alpha\rho_k + M^2\rho_k^2\right)^{1/2} \leq \beta < 1 \quad \text{for all } k \geq 0.$$

Since the minimizing point $u \in U$ is a fixed point of g_k for all k , by letting $v_1 = u_k$ and $v_2 = u$, we get

$$\|u_{k+1} - u\| = \|g_k(u_k) - g_k(u)\| \leq \beta \|u_k - u\|,$$

which proves the convergence of the sequence $(u_k)_{k \geq 0}$. \square

In the case of an elliptic quadratic functional

$$J(v) = \frac{1}{2} \langle Av, v \rangle - \langle b, v \rangle$$

defined on \mathbb{R}^n , the reasoning just after the proof of Proposition 49.14 can be immediately adapted to show that convergence takes place as long as a, b and ρ_k are chosen such that

$$0 < a \leq \rho_k \leq b \leq \frac{2}{\lambda_n}.$$

In theory, Proposition 49.18 gives a guarantee of the convergence of the projected-gradient method. Unfortunately, because computing the projection $p_U(v)$ effectively is generally impossible, the range of practical applications of Proposition 49.18 is rather limited. One exception is the case where U is a product $\prod_{i=1}^m [a_i, b_i]$ of closed intervals (where $a_i = -\infty$ or $b_i = +\infty$ is possible). In this case, it is not hard to show that

$$p_U(w)_i = \begin{cases} a_i & \text{if } w_i < a_i \\ w_i & \text{if } a_i \leq w_i \leq b_i \\ b_i & \text{if } b_i < w_i. \end{cases}$$

In particular, this is the case if

$$U = \mathbb{R}_+^n = \{v \in \mathbb{R}^n \mid v \geq 0\}$$

and if

$$J(v) = \frac{1}{2}\langle Av, a \rangle - \langle b, v \rangle$$

is an elliptic quadratic functional on \mathbb{R}^n . Then the vector $u_{k+1} = (u_1^{k+1}, \dots, u_n^{k+1})$ is given in terms of $u_k = (u_1^k, \dots, u_n^k)$ by

$$u_i^{k+1} = \max\{u_i^k - \rho_k(Au_k - b)_i, 0\}, \quad 1 \leq i \leq n.$$

49.12 Penalty Methods for Constrained Optimization

In the case where $V = \mathbb{R}^n$, another method to deal with constrained optimization is to incorporate the domain U into the objective function J by adding a penalty function.

Definition 49.11. Given a nonempty closed convex subset U of \mathbb{R}^n , a function $\psi: \mathbb{R}^n \rightarrow \mathbb{R}$ is called a *penalty function* for U if ψ is convex and continuous and if the following conditions hold:

$$\psi(v) \geq 0 \quad \text{for all } v \in \mathbb{R}^n, \quad \text{and} \quad \psi(v) = 0 \quad \text{iff} \quad v \in U.$$

The following proposition shows that the use of penalty functions reduces a constrained optimization problem to a sequence of unconstrained optimization problems.

Proposition 49.19. Let $J: \mathbb{R}^n \rightarrow \mathbb{R}$ be a continuous, coercive, strictly convex function, U be a nonempty, convex, closed subset of \mathbb{R}^n , $\psi: \mathbb{R}^n \rightarrow \mathbb{R}$ be a penalty function for U , and let $J_\epsilon: \mathbb{R}^n \rightarrow \mathbb{R}$ be the penalized objective function given by

$$J_\epsilon(v) = J(v) + \frac{1}{\epsilon}\psi(v) \quad \text{for all } v \in \mathbb{R}^n.$$

Then for every $\epsilon > 0$, there exists a unique element $u_\epsilon \in \mathbb{R}^n$ such that

$$J_\epsilon(u_\epsilon) = \inf_{v \in \mathbb{R}^n} J_\epsilon(v).$$

Furthermore, if $u \in U$ is the unique minimizer of J over U , so that $J(u) = \inf_{v \in U} J(v)$, then

$$\lim_{\epsilon \rightarrow 0} u_\epsilon = u.$$

Proof. Observe that since J is coercive, since $\psi(v) \geq 0$ for all $v \in \mathbb{R}^n$, and $J_\epsilon = J + (1/\epsilon)\psi$, we have $J_\epsilon(v) \geq J(v)$ for all $v \in \mathbb{R}^n$, so J_ϵ is also coercive. Since J is strictly convex and $(1/\epsilon)\psi$ is convex, it is immediately checked that $J_\epsilon = J + (1/\epsilon)\psi$ is also strictly convex. Then by Proposition 49.1 (and the fact that J and J_ϵ are strictly convex), J has a unique minimizer $u \in U$, and J_ϵ has a unique minimizer $u_\epsilon \in \mathbb{R}^n$.

Since $\psi(u) = 0$ iff $u \in U$, and $\psi(v) \geq 0$ for all $v \in \mathbb{R}^n$, we have $J_\epsilon(u) = J(u)$, and since u_ϵ is the minimizer of J_ϵ we have $J_\epsilon(u_\epsilon) \leq J_\epsilon(u)$, so we obtain

$$J(u_\epsilon) \leq J(u_\epsilon) + \frac{1}{\epsilon} \psi(u_\epsilon) = J_\epsilon(u_\epsilon) \leq J_\epsilon(u) = J(u),$$

that is,

$$J_\epsilon(u_\epsilon) \leq J(u). \quad (*_1)$$

Since J is coercive, the family $(u_\epsilon)_{\epsilon > 0}$ is bounded. By compactness (since we are in \mathbb{R}^n), there exists a subsequence $(u_{\epsilon(i)})_{i \geq 0}$ with $\lim_{i \rightarrow \infty} \epsilon(i) = 0$ and some element $u' \in \mathbb{R}^n$ such that

$$\lim_{i \rightarrow \infty} u_{\epsilon(i)} = u'.$$

From the inequality $J(u_\epsilon) \leq J(u)$ proven in $(*_1)$ and the continuity of J , we deduce that

$$J(u') = \lim_{i \rightarrow \infty} J(u_{\epsilon(i)}) \leq J(u). \quad (*_2)$$

By definition of $J_\epsilon(u_\epsilon)$ and $(*_1)$, we have

$$0 \leq \psi(u_{\epsilon(i)}) \leq \epsilon(i)(J(u) - J(u_{\epsilon(i)})),$$

and since the sequence $(u_{\epsilon(i)})_{i \geq 0}$ converges, the numbers $J(u) - J(u_{\epsilon(i)})$ are bounded independently of i . Consequently, since $\lim_{i \rightarrow \infty} \epsilon(i) = 0$ and since the function ψ is continuous, we have

$$0 = \lim_{i \rightarrow \infty} \psi(u_{\epsilon(i)}) = \psi(u'),$$

which shows that $u' \in U$. Since by $(*_2)$ we have $J(u') \leq J(u)$, and since both $u, u' \in U$ and u is the unique minimizer of J over U we must have $u' = u$. Therefore u' is the unique minimizer of J over U . But then the whole family $(u_\epsilon)_{\epsilon > 0}$ converges to u since we can use the same argument as above for *every* subsequence of $(u_\epsilon)_{\epsilon > 0}$. \square

Note that a convex function $\psi: \mathbb{R}^n \rightarrow \mathbb{R}$ is automatically continuous, so the assumption of continuity is redundant.

As an application of Proposition 49.19, if U is given by

$$U = \{v \in \mathbb{R}^n \mid \varphi_i(v) \leq 0, i = 1, \dots, m\},$$

where the functions $\varphi_i: \mathbb{R}^n \rightarrow \mathbb{R}$ are convex, we can take ψ to be the function given by

$$\psi(v) = \sum_{i=1}^m \max\{\varphi_i(v), 0\}.$$

In practice, the applicability of the penalty-function method is limited by the difficulty to construct effectively “good” functions ψ , for example, differentiable ones. Note that in the above example the function ψ is not differentiable. A better penalty function is

$$\psi(v) = \sum_{i=1}^m (\max\{\varphi_i(v), 0\})^2.$$

Another way to deal with constrained optimization problems is to use *duality*. This approach is investigated in Chapter 50.

49.13 Summary

The main concepts and results of this chapter are listed below:

- Minimization, minimizer.
- Coercive functions.
- Minima of quadratic functionals.
- The theorem of Lions and Stampacchia.
- Lax–Milgram’s theorem.
- Elliptic functionals.
- Descent direction, exact line search, backtracking line search.
- Method of relaxation.
- Gradient descent.
- Gradient descent method with fixed stepsize parameter.
- Gradient descent method with variable stepsize parameter.
- Steepest descent method for the Euclidean norm.
- Gradient descent method with backtracking line search.
- Normalized steepest descent direction.
- Unnormalized steepest descent direction.
- Steepest descent method (with respect to the norm $\|\cdot\|$).
- Momentum term.

- Newton's method.
- Newton step.
- Newton decrement.
- Damped Newton phase.
- Quadratically convergent phase.
- Self-concordant functions.
- Conjugate gradient method.
- Projected gradient methods.
- Penalty methods.

49.14 Problems

Problem 49.1. Consider the function $J: \mathbb{R}^n \rightarrow \mathbb{R}$ given by

$$J(v) = \frac{1}{2}\langle Av, v\rangle - \langle b, v\rangle + g(v),$$

where A is a real $n \times n$ symmetric positive definite matrix, $b \in \mathbb{R}^n$, and $g: \mathbb{R}^n \rightarrow \mathbb{R}$ is a continuous (not necessarily differentiable) convex function such that $g(v) \geq 0$ for all $v \in \mathbb{R}^n$, and let U be a nonempty, bounded, closed, convex subset of \mathbb{R}^n .

- (1) Prove that there is a unique element $u \in U$ such that

$$J(u) = \inf_{v \in U} J(v).$$

Hint. Prove that J is strictly convex on \mathbb{R}^n .

- (2) Check that

$$J(v) - J(u) = \langle Au - b, v - u\rangle + g(v) - g(u) + \frac{1}{2}\langle A(v - u), v - u\rangle.$$

Prove that an element $u \in U$ minimizes J in U iff

$$\langle Au - b, v - u\rangle + g(v) - g(u) \geq 0 \quad \text{for all } v \in U.$$

Problem 49.2. Consider n piecewise C^1 functions $\varphi_i: [0, 1] \rightarrow \mathbb{R}$ and assume that these functions are linearly independent and that

$$\sum_{i=1}^n \varphi_i(x) = 1 \quad \text{for all } x \in [0, 1].$$

Let $J: \mathbb{R}^n \rightarrow \mathbb{R}$ be the function given by

$$J(v) = \sum_{i,j=1}^n a_{ij}v_i v_j + \sum_{i=1}^n b_i v_i,$$

where $v = (v_1, \dots, v_n)$ and

$$a_{ij} = \int_0^1 \varphi'_i(t) \varphi'_j(t) dt, \quad b_i = \int_0^1 \varphi_i(t) dt.$$

(1) Let U_1 be the subset of \mathbb{R}^n given by

$$U_1 = \left\{ v \in \mathbb{R}^n \mid \sum_{i=1}^n b_i v_i = 0 \right\}.$$

Consider the problem of finding a minimum of J over U_1 . Prove that the Lagrange multiplier λ for which the Lagrangian has a critical point is $\lambda = -1$.

(2) Prove that the map defined on U_1 by

$$\|v\| = \left(\int_0^1 \left(\sum_{i=1}^n v_i \varphi'_i(x) \right)^2 dx \right)^{1/2}$$

is a norm. Prove that J is elliptic on U_1 with this norm. Prove that J has a unique minimum on U_1 .

(3) Consider the the subset of \mathbb{R}^n given by

$$U_2 = \left\{ v \in \mathbb{R}^n \mid \sum_{i=1}^n (\varphi_i(1) + \varphi_i(0)) v_i = 0 \right\}.$$

Consider the problem of finding a minimum of J over U_2 . Prove that the Lagrange multiplier λ for which the Lagrangian has a critical point is $\lambda = -1/2$. Prove that J is elliptic on U_2 with the same norm as in (2). Prove that J has a unique minimum on U_2 .

(4) Consider the the subset of \mathbb{R}^n given by

$$U_3 = \left\{ v \in \mathbb{R}^n \mid \sum_{i=1}^n (\varphi_i(1) - \varphi_i(0)) v_i = 0 \right\}.$$

This time show that the necessary condition for having a minimum on U_3 yields the equation $1 + \lambda(1 - 1) = 0$. Conclude that J does not have a minimum on U_3 .

Problem 49.3. Let A be a real $n \times n$ symmetric positive definite matrix and let $b \in \mathbb{R}^n$.

(1) Prove that if we apply the steepest descent method (for the Euclidean norm) to

$$J(v) = \frac{1}{2}\langle Av, v \rangle - \langle b, v \rangle,$$

and if we define the norm $\|v\|_A$ by

$$\|v\|_A = \langle Av, v \rangle^{1/2},$$

we get the inequality

$$\|u_{k+1} - u\|_A^2 \leq \|u_k - u\|_A^2 \left(1 - \frac{\|A(u_k - u)\|_2^4}{\|u_k - u\|_A^2 \|A(u_k - u)\|_A^2}\right).$$

(2) Using a diagonalization of A , where the eigenvalues of A are denoted $0 < \lambda_1 \leq \lambda_2 \leq \dots \leq \lambda_n$, prove that

$$\|u_{k+1} - u\|_A \leq \frac{\text{cond}_2(A) - 1}{\text{cond}_2(A) + 1} \|u_k - u\|_A,$$

where $\text{cond}_2(A) = \lambda_n/\lambda_1$, and thus

$$\|u_k - u\|_A \leq \left(\frac{\text{cond}_2(A) - 1}{\text{cond}_2(A) + 1}\right)^k \|u_0 - u\|_A.$$

(3) Prove that when $\text{cond}_2(A) = 1$, then $A = I$ and the method converges in one step.

Problem 49.4. Prove that the method of Polak–Ribi  re converges if $J: \mathbb{R}^n \rightarrow \mathbb{R}$ is elliptic and a C^2 function.

Problem 49.5. Prove that the backtracking line search method described in Section 49.5 has the property that for t small enough the condition $J(u_k + td_k) \leq J(u_k) + \alpha t \langle \nabla J_{u_k}, d_k \rangle$ will hold and the search will stop. Prove that the exit inequality $J(u_k + td_k) \leq J(u_k) + \alpha t \langle \nabla J_{u_k}, d_k \rangle$ holds for all $t \in (0, t_0]$, for some $t_0 > 0$, so the backtracking line search stops with a step length ρ_k that satisfies $\rho_k = 1$ or $\rho_k \in (\beta t_0, t_0]$.

Problem 49.6. Let $d_{\text{nsd},k}$ and $d_{\text{sd},k}$ be the normalized and unnormalized descent directions of the steepest descent method for an arbitrary norm (see Section 49.8). Prove that

$$\begin{aligned} \langle \nabla J_{u_k}, d_{\text{nsd},k} \rangle &= -\|\nabla J_{u_k}\|^D \\ \langle \nabla J_{u_k}, d_{\text{sd},k} \rangle &= -(\|\nabla J_{u_k}\|^D)^2 \\ d_{\text{sd},k} &= \arg \min_v \left(\langle \nabla J_{u_k}, v \rangle + \frac{1}{2} \|v\|^2 \right). \end{aligned}$$

Problem 49.7. If P is a symmetric positive definite matrix, prove that $\|z\|_P = (z^\top P z)^{1/2} = \|P^{1/2}z\|_2$ is a norm. Prove that the normalized steepest descent direction is

$$d_{\text{nsd},k} = -(\nabla J_{u_k}^\top P^{-1} \nabla J_{u_k})^{-1/2} P^{-1} \nabla J_{u_k},$$

the dual norm is $\|z\|^D = \|P^{-1/2}z\|_2$, and the steepest descent direction with respect to $\|\cdot\|_P$ is given by

$$d_{\text{sd},k} = -P^{-1} \nabla J_{u_k}.$$

Problem 49.8. If $\|\cdot\|$ is the ℓ^1 -norm, then show that $d_{\text{nsd},k}$ is determined as follows: let i be any index for which $\|\nabla J_{u_k}\|_\infty = |(\nabla J_{u_k})_i|$. Then

$$d_{\text{nsd},k} = -\text{sign}\left(\frac{\partial J}{\partial x_i}(u_k)\right) e_i,$$

where e_i is the i th canonical basis vector, and

$$d_{\text{sd},k} = -\frac{\partial J}{\partial x_i}(u_k) e_i.$$

Problem 49.9. (From Boyd and Vandenberghe [29], Problem 9.12). If $\nabla^2 f(x)$ is singular (or very ill-conditioned), the Newton step $d_{\text{nt}} = -(\nabla^2 f(x))^{-1} \nabla f(x)$ is not well defined. Instead we can define a search direction d_{tr} as the solution of the problem

$$\begin{aligned} & \text{minimize} && (1/2)\langle Hv, v\rangle + \langle g, v\rangle \\ & \text{subject to} && \|v\|_2 \leq \gamma, \end{aligned}$$

where $H = \nabla^2 f(x)$, $g = \nabla f(x)$, and γ is some positive constant. The idea is to use a *trust region*, which is the closed ball $\{v \mid \|v\|_2 \leq \gamma\}$. The point $x + d_{\text{tr}}$ minimizes the second-order approximation of f at x , subject to the constraint that

$$\|x + d_{\text{tr}} - x\|_2 \leq \gamma.$$

The parameter γ , called the *trust parameter*, reflects our confidence in the second-order approximation.

Prove that d_{tr} minimizes

$$\frac{1}{2}\langle Hv, v\rangle + \langle g, v\rangle + \widehat{\beta} \|v\|_2^2,$$

for some $\widehat{\beta}$.

Problem 49.10. (From Boyd and Vandenberghe [29], Problem 9.9). Prove that the Newton decrement $\lambda(x)$ is given by

$$\lambda(x) = \sup_{v \neq 0} -\frac{\langle \nabla f(x), v\rangle}{(\langle \nabla^2 f(x)v, v\rangle)^{1/2}}.$$

Problem 49.11. Show that the function f given by $f(x) = \log(e^x + e^{-x})$ has a unique minimum for $x^* = 0$. Run Newton's method with fixed step size $t = 1$, starting with $x_0 = 1$, and then $x_0 = 1.1$. What do you observe?

Problem 49.12. Write a Matlab program implementing the conjugate gradient method. Test your program with the $n \times n$ matrix

$$A_n = \begin{pmatrix} 2 & -1 & 0 & \cdots & 0 \\ -1 & 2 & -1 & \cdots & 0 \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & \cdots & -1 & 2 & -1 \\ 0 & \cdots & 0 & -1 & 2 \end{pmatrix}$$

and various right-hand sides, for various values of n . Verify that the running time is $O(n^{3/2})$.

Chapter 50

Introduction to Nonlinear Optimization

This chapter contains the most important results of nonlinear optimization theory.

In Chapter 40 we investigated the problem of determining when a function $J: \Omega \rightarrow \mathbb{R}$ defined on some open subset Ω of a normed vector space E has a local extremum in a subset U of Ω defined by equational constraints, namely

$$U = \{x \in \Omega \mid \varphi_i(x) = 0, \quad 1 \leq i \leq m\},$$

where the functions $\varphi_i: \Omega \rightarrow \mathbb{R}$ are continuous (and usually differentiable). Theorem 40.2 gave a necessary condition in terms of the Lagrange multipliers. In Section 40.3 we assumed that U was a convex subset of Ω ; then Theorem 40.9 gave us a necessary condition for the function $J: \Omega \rightarrow \mathbb{R}$ to have a local minimum at u with respect to U if dJ_u exists, namely

$$dJ_u(v - u) \geq 0 \quad \text{for all } v \in U.$$

Our first goal is to find a necessary criterion for a function $J: \Omega \rightarrow \mathbb{R}$ to have a minimum on a subset U , even if this subset is *not* convex. This can be done by introducing a notion of “tangent cone” at a point $u \in U$. We define the cone of feasible directions and then state a necessary condition for a function to have local minimum on a set U that is not necessarily convex in terms of the cone of feasible directions. The cone of feasible directions is not always convex, but it is if the constraints are inequality constraints. An inequality constraint $\varphi(u) \leq 0$ is said to be *active* if $\varphi(u) = 0$. One can also define the notion of *qualified constraint*. Theorem 50.5 gives necessary conditions for a function J to have a minimum on a subset U defined by qualified inequality constraints in terms of the Karush–Kuhn–Tucker conditions (for short KKT conditions), which involve nonnegative Lagrange multipliers. The proof relies on a version of the Farkas–Minkowski lemma. Some of the KTT conditions assert that $\lambda_i \varphi_i(u) = 0$, where $\lambda_i \geq 0$ is the Lagrange multiplier associated with the constraint $\varphi_i \leq 0$. To some extent, this implies that active constraints are more important than inactive constraints, since if $\varphi_i(u) < 0$ is an inactive constraint, then $\lambda_i = 0$. In general,

the KKT conditions are useless unless the constraints are convex. In this case, there is a manageable notion of qualified constraint given by Slater's conditions. Theorem 50.6 gives necessary conditions for a function J to have a minimum on a subset U defined by convex inequality constraints in terms of the Karush–Kuhn–Tucker conditions. Furthermore, if J is also convex and if the KKT conditions hold, then J has a global minimum.

In Section 50.4, we apply Theorem 50.6 to the special case where the constraints are equality constraints, which can be expressed as $Ax = b$. In the special case where the convex objective function J is a convex quadratic functional of the form

$$J(x) = \frac{1}{2}x^\top Px + q^\top x + r,$$

where P is a $n \times n$ symmetric positive semidefinite matrix, the necessary and sufficient conditions for having a minimum are expressed by a linear system involving a matrix called the KKT matrix. We discuss conditions that guarantee that the KKT matrix is invertible, and how to solve the KKT system. We also briefly discuss variants of Newton's method dealing with equality constraints.

We illustrate the KKT conditions on an interesting example, the so-called hard margin support vector machine; see Sections 50.5 and 50.6. The problem is a classification problem, or more accurately a separation problem. Suppose we have two nonempty disjoint finite sets of p blue points $\{u_i\}_{i=1}^p$ and q red points $\{v_j\}_{j=1}^q$ in \mathbb{R}^n . Our goal is to find a hyperplane H of equation $w^\top x - b = 0$ (where $w \in \mathbb{R}^n$ is a nonzero vector and $b \in \mathbb{R}$), such that all the blue points u_i are in one of the two open half-spaces determined by H , and all the red points v_j are in the other open half-space determined by H .

If the two sets are indeed separable, then in general there are infinitely many hyperplanes separating them. Vapnik had the idea to find a hyperplane that maximizes the smallest distance between the points and the hyperplane. Such a hyperplane is indeed unique and is called a maximal hard margin hyperplane, or hard margin support vector machine. The support vectors are those for which the constraints are active.

Section 50.7 contains the most important results of the chapter. The notion of Lagrangian duality is presented. Given a primal optimization problem (P) consisting in minimizing an objective function $J(v)$ with respect to some inequality constraints $\varphi_i(v) \leq 0$, $i = 1, \dots, m$, we define the *dual function* $G(\mu)$ as the result of minimizing the Lagrangian

$$L(v, \mu) = J(v) + \sum_{i=1}^m \mu_i \varphi_i(v)$$

with respect to v , with $\mu \in \mathbb{R}_+^m$. The dual program (D) is then to maximize $G(\mu)$ with respect to $\mu \in \mathbb{R}_+^m$. It turns out that G is a concave function, and the dual program is an unconstrained maximization. This is actually a misleading statement because G is generally a partial function, so maximizing $G(\mu)$ is equivalent to a constrained maximization problem in which the constraints specify the domain of G , but in many cases, we obtain a dual

program simpler than the primal program. If d^* is the optimal value of the dual program and if p^* is the optimal value of the primal program, we always have

$$d^* \leq p^*,$$

which is known as *weak duality*. Under certain conditions, $d^* = p^*$, that is, the duality gap is zero, in which case we say that *strong duality* holds. Also, under certain conditions, a solution of the dual yields a solution of the primal, and if the primal has an optimal solution, then the dual has an optimal solution, but beware that the converse is generally false (see Theorem 50.17). We also show how to deal with equality constraints, and discuss the use of conjugate functions to find the dual function. Our coverage of Lagrangian duality is quite thorough, but we do not discuss more general orderings such as the semidefinite ordering. For these topics which belong to convex optimization, the reader is referred to Boyd and Vandenberghe [29].

Our approach in this chapter is very much inspired by Ciarlet [41] because we find it one of the more direct, and it is general enough to accommodate Hilbert spaces. The field of nonlinear optimization and convex optimization is vast and there are many books on the subject. Among those we recommend (in alphabetic order) Bertsekas [16, 17, 18], Bertsekas, Nedić, and Ozdaglar [19], Boyd and Vandenberghe [29], Luenberger [116], and Luenberger and Ye [117].

50.1 The Cone of Feasible Directions

Let V be a normed vector space and let U be a nonempty subset of V . For any point $u \in U$, consider any converging sequence $(u_k)_{k \geq 0}$ of vectors $u_k \in U$ having u as their limit, with $u_k \neq u$ for all $k \geq 0$, and look at the sequence of “unit chords,”

$$\frac{u_k - u}{\|u_k - u\|}.$$

This sequence could oscillate forever, or it could have a limit, some unit vector $\hat{w} \in V$. In the second case, all nonzero vectors $\lambda \hat{w}$ for all $\lambda > 0$, belong to an object called the cone of feasible directions at u . First, we need to define the notion of cone.

Definition 50.1. Given a (real) vector space V , a nonempty subset $C \subseteq V$ is a *cone with apex 0* (for short, a *cone*), if for any $v \in V$, if $v \in C$, then $\lambda v \in C$ for all $\lambda > 0$ ($\lambda \in \mathbb{R}$). For any $u \in V$, a *cone with apex u* is any nonempty subset of the form $u + C = \{u + v \mid v \in C\}$, where C is a cone with apex 0; see Figure 50.1.

Observe that a cone with apex 0 (or u) is not necessarily convex, and that 0 does not necessarily belong to C (resp. u does not necessarily belong to $u + C$) (although in the case of the cone of feasible directions $C(u)$ we have $0 \in C(u)$). The condition for being a cone only asserts that if a nonzero vector v belongs to C , then the open ray $\{\lambda v \mid \lambda > 0\}$ (resp. the affine open ray $u + \{\lambda v \mid \lambda > 0\}$) also belongs to C .

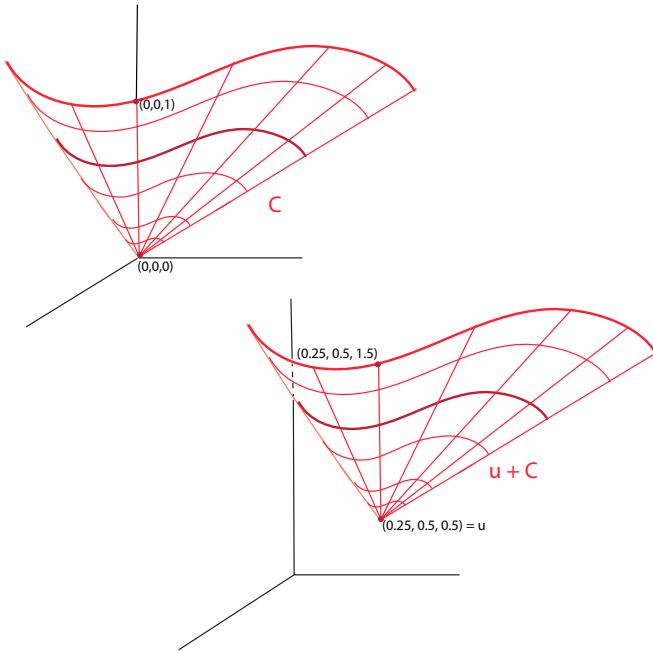

Figure 50.1: Let C be the cone determined by the bold orange curve through $(0, 0, 1)$ in the plane $z = 1$. Then $u + C$, where $u = (0.25, 0.5, 0.5)$, is the affine translate of C via the vector u .

Definition 50.2. Let V be a normed vector space and let U be a nonempty subset of V . For any point $u \in U$, the *cone $C(u)$ of feasible directions at u* is the union of $\{0\}$ and the set of all nonzero vectors $w \in V$ for which there exists some convergent sequence $(u_k)_{k \geq 0}$ of vectors such that

$$(1) \quad u_k \in U \text{ and } u_k \neq u \text{ for all } k \geq 0, \text{ and } \lim_{k \rightarrow \infty} u_k = u.$$

$$(2) \quad \lim_{k \rightarrow \infty} \frac{u_k - u}{\|u_k - u\|} = \frac{w}{\|w\|}, \text{ with } w \neq 0.$$

Condition (2) can also be expressed as follows: there is a sequence $(\delta_k)_{k \geq 0}$ of vectors $\delta_k \in V$ such that

$$u_k = u + \|u_k - u\| \frac{w}{\|w\|} + \|u_k - u\| \delta_k, \quad \lim_{k \rightarrow \infty} \delta_k = 0, \quad w \neq 0.$$

Figure 50.2 illustrates the construction of w in $C(u)$.

Clearly, the cone $C(u)$ of feasible directions at u is a cone with apex 0, and $u + C(u)$ is a cone with apex u . Obviously, it would be desirable to have conditions on U that imply that $C(u)$ is a convex cone. Such conditions will be given later on.

Observe that the cone $C(u)$ of feasible directions at u contains the velocity vectors at u of all curves γ in U through u . If $\gamma: (-1, 1) \rightarrow U$ is such a curve with $\gamma(0) = u$, and if $\gamma'(u) \neq 0$

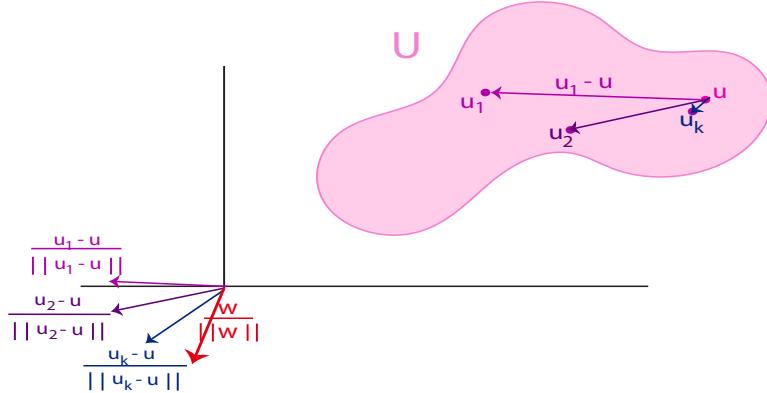

Figure 50.2: Let U be the pink region in \mathbb{R}^2 with fuchsia point $u \in U$. For any sequence $(u_k)_{k \geq 0}$ of points in U which converges to u , form the chords $u_k - u$ and take the limit to construct the red vector w .

exists, then there is a sequence $(u_k)_{k \geq 0}$ of vectors in U converging to u as in Definition 50.2, with $u_k = \gamma(t_k)$ for some sequence $(t_k)_{k \geq 0}$ of reals $t_k > 0$ such that $\lim_{k \rightarrow \infty} t_k = 0$, so that

$$u_k - u = t_k \gamma'(0) + t_k \epsilon_k, \quad \lim_{k \rightarrow \infty} \epsilon_k = 0,$$

and we get

$$\lim_{k \rightarrow \infty} \frac{u_k - u}{\|u_k - u\|} = \frac{\gamma'(0)}{\|\gamma'(0)\|}.$$

For an illustration of this paragraph in \mathbb{R}^2 , see Figure 50.3.

Example 50.1. In $V = \mathbb{R}^2$, let φ_1 and φ_2 be given by

$$\begin{aligned} \varphi_1(u_1, u_2) &= -u_1 - u_2 \\ \varphi_2(u_1, u_2) &= u_1(u_1^2 + u_2^2) - (u_1^2 - u_2^2), \end{aligned}$$

and let

$$U = \{(u_1, u_2) \in \mathbb{R}^2 \mid \varphi_1(u_1, u_2) \leq 0, \varphi_2(u_1, u_2) \leq 0\}.$$

The region U is shown in Figure 50.4 and is bounded by the curve given by the equation $\varphi_1(u_1, u_2) = 0$, that is, $-u_1 - u_2 = 0$, the line of slope -1 through the origin, and the curve given by the equation $u_1(u_1^2 + u_2^2) - (u_1^2 - u_2^2) = 0$, a nodal cubic through the origin. We obtain a parametric definition of this curve by letting $u_2 = tu_1$, and we find that

$$u_1(t) = \frac{u_1^2(t) - u_2^2(t)}{u_1^2(t) + u_2^2(t)} = \frac{1 - t^2}{1 + t^2}, \quad u_2(t) = \frac{t(1 - t^2)}{1 + t^2}.$$

The tangent vector at t is given by $(u'_1(t), u'_2(t))$ with

$$u'_1(t) = \frac{-2t(1 + t^2) - (1 - t^2)2t}{(1 + t^2)^2} = \frac{-4t}{(1 + t^2)^2}$$

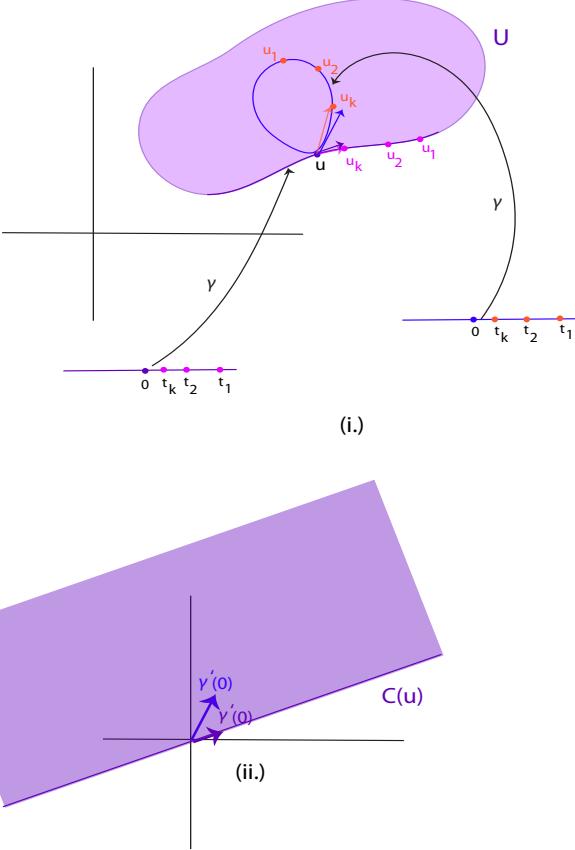

Figure 50.3: Let U be purple region in \mathbb{R}^2 and u be the designated point on the boundary of U . Figure (i.) illustrates two curves through u and two sequences $(u_k)_{k \geq 0}$ converging to u . The limit of the chords $u_k - u$ corresponds to the tangent vectors for the appropriate curve. Figure (ii.) illustrates the half plane $C(u)$ of feasible directions.

and

$$u'_2(t) = \frac{(1-3t^2)(1+t^2) - (t-t^3)2t}{(1+t^2)^2} = \frac{1-2t^2-3t^4-2t^2+2t^4}{(1+t^2)^2} = \frac{1-4t^2-t^4}{(1+t^2)^2}.$$

The nodal cubic passes through the origin for $t = \pm 1$, and for $t = -1$ the tangent vector is $(1, -1)$, and for $t = 1$ the tangent vector is $(-1, -1)$. The cone of feasible directions $C(0)$ at the origin is given by

$$C(0) = \{(u_1, u_2) \in \mathbb{R}^2 \mid u_1 + u_2 \geq 0, |u_1| \geq |u_2|\}.$$

This is not a convex cone since it contains the sector delineated by the lines $u_2 = u_1$ and $u_2 = -u_1$, but also the ray supported by the vector $(-1, 1)$.

The two crucial properties of the cone of feasible directions are shown in the following proposition.

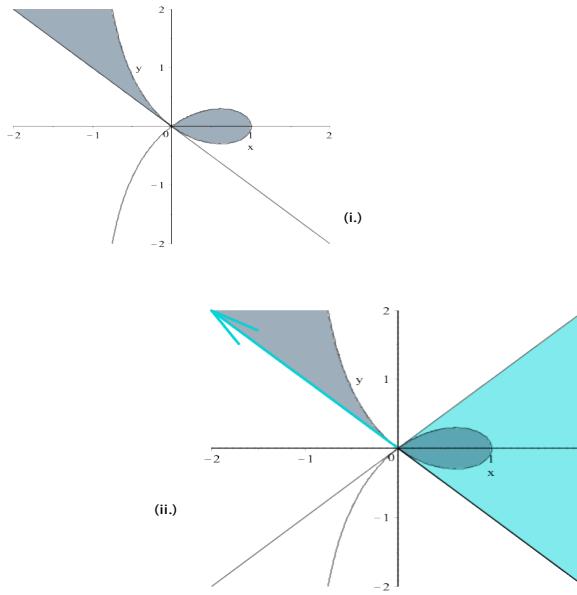

Figure 50.4: Figure (i.) illustrates U as the shaded gray region which lies between the line $y = -x$ and nodal cubic. Figure (ii.) shows the cone of feasible directions, $C(0)$, as the union of the turquoise triangular cone and the turquoise directional ray $(-1, 1)$.

Proposition 50.1. *Let U be any nonempty subset of a normed vector space V .*

- (1) *For any $u \in U$, the cone $C(u)$ of feasible directions at u is closed.*
- (2) *Let $J: \Omega \rightarrow \mathbb{R}$ be a function defined on an open subset Ω containing U . If J has a local minimum with respect to the set U at a point $u \in U$, and if J'_u exists at u , then*

$$J'_u(v - u) \geq 0 \quad \text{for all } v \in u + C(u).$$

Proof. (1) Let $(w_n)_{n \geq 0}$ be a sequence of vectors $w_n \in C(u)$ converging to a limit $w \in V$. We may assume that $w \neq 0$, since $0 \in C(u)$ by definition, and thus we may also assume that $w_n \neq 0$ for all $n \geq 0$. By definition, for every $n \geq 0$, there is a sequence $(u_k^n)_{k \geq 0}$ of vectors in V and some $w_n \neq 0$ such that

- (1) $u_k^n \in U$ and $u_k^n \neq u$ for all $k \geq 0$, and $\lim_{k \rightarrow \infty} u_k^n = u$.
- (2) There is a sequence $(\delta_k^n)_{k \geq 0}$ of vectors $\delta_k^n \in V$ such that

$$u_k^n = u + \|u_k^n - u\| \frac{w_n}{\|w_n\|} + \|u_k^n - u\| \delta_k^n, \quad \lim_{k \rightarrow \infty} \delta_k^n = 0, \quad w_n \neq 0.$$

Let $(\epsilon_n)_{n \geq 0}$ be a sequence of real numbers $\epsilon_n > 0$ such that $\lim_{n \rightarrow \infty} \epsilon_n = 0$ (for example, $\epsilon_n = 1/(n+1)$). Due to the convergence of the sequences (u_k^n) and (δ_k^n) for every fixed n ,

there exist an integer $k(n)$ such that

$$\|u_{k(n)}^n - u\| \leq \epsilon_n, \quad \|\delta_{k(n)}^n\| \leq \epsilon_n.$$

Consider the sequence $(u_{k(n)}^n)_{n \geq 0}$. We have

$$u_{k(n)}^n \in U, \quad u_{k(n)}^n \neq 0, \quad \text{for all } n \geq 0, \quad \lim_{n \rightarrow \infty} u_{k(n)}^n = u,$$

and we can write

$$u_{k(n)}^n = u + \|u_{k(n)}^n - u\| \frac{w}{\|w\|} + \|u_{k(n)}^n - u\| \left(\delta_{k(n)}^n + \left(\frac{w_n}{\|w_n\|} - \frac{w}{\|w\|} \right) \right).$$

Since $\lim_{k \rightarrow \infty} (w_n / \|w_n\|) = w / \|w\|$, we conclude that $w \in C(u)$. See Figure 50.5.

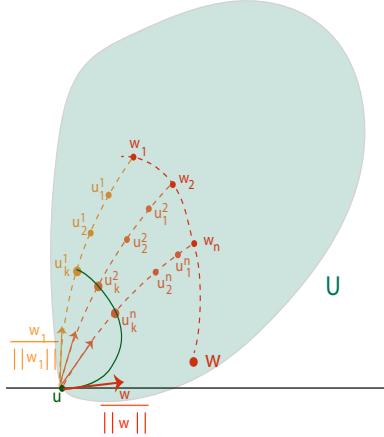

Figure 50.5: Let U be the mint green region in \mathbb{R}^2 with $u = (0, 0)$. Let $(w_n)_{n \geq 0}$ be a sequence of vectors (points) along the upper dashed curve which converge to w . By following the dashed orange longitudinal curves, and selecting an appropriate vector (point), we construct the dark green curve in U , which passes through u , and at u has tangent vector proportional to w .

(2) Let $w = v - u$ be any nonzero vector in the cone $C(u)$, and let $(u_k)_{k \geq 0}$ be a sequence of vectors in $U - \{u\}$ such that

$$(1) \quad \lim_{k \rightarrow \infty} u_k = u.$$

$$(2) \quad \text{There is a sequence } (\delta_k)_{k \geq 0} \text{ of vectors } \delta_k \in V \text{ such that}$$

$$u_k - u = \|u_k - u\| \frac{w}{\|w\|} + \|u_k - u\| \delta_k, \quad \lim_{k \rightarrow \infty} \delta_k = 0, \quad w \neq 0,$$

$$(3) \quad J(u) \leq J(u_k) \text{ for all } k \geq 0.$$

Since J is differentiable at u , we have

$$0 \leq J(u_k) - J(u) = J'_u(u_k - u) + \|u_k - u\| \epsilon_k, \quad (*)$$

for some sequence $(\epsilon_k)_{k \geq 0}$ such that $\lim_{k \rightarrow \infty} \epsilon_k = 0$. Since J'_u is linear and continuous, and since

$$u_k - u = \|u_k - u\| \frac{w}{\|w\|} + \|u_k - u\| \delta_k, \quad \lim_{k \rightarrow \infty} \delta_k = 0, \quad w \neq 0,$$

$(*)$ implies that

$$0 \leq \frac{\|u_k - u\|}{\|w\|} (J'_u(w) + \eta_k),$$

with

$$\eta_k = \|w\| (J'_u(\delta_k) + \epsilon_k).$$

Since J'_u is continuous, we have $\lim_{k \rightarrow \infty} \eta_k = 0$. But then $J'_u(w) \geq 0$, since if $J'_u(w) < 0$, then for k large enough the expression $J'_u(w) + \eta_k$ would be negative, and since $u_k \neq u$, the expression $(\|u_k - u\| / \|w\|)(J'_u(w) + \eta_k)$ would also be negative, a contradiction. \square

From now on we assume that U is defined by a set of inequalities, that is

$$U = \{x \in \Omega \mid \varphi_i(x) \leq 0, \quad 1 \leq i \leq m\},$$

where the functions $\varphi_i: \Omega \rightarrow \mathbb{R}$ are continuous (and usually differentiable). As we explained earlier, an equality constraint $\varphi_i(x) = 0$ is treated as the conjunction of the two inequalities $\varphi_i(x) \leq 0$ and $-\varphi_i(x) \leq 0$. Later on we will see that when the functions φ_i are convex, since $-\varphi_i$ is not necessarily convex, it is desirable to treat equality constraints separately, but for the time being we won't.

50.2 Active Constraints and Qualified Constraints

Our next goal is find sufficient conditions for the cone $C(u)$ to be convex, for any $u \in U$. For this we assume that the functions φ_i are differentiable at u . It turns out that the constraints φ_i that matter are those for which $\varphi_i(u) = 0$, namely the constraints that are tight, or as we say, active.

Definition 50.3. Given m functions $\varphi_i: \Omega \rightarrow \mathbb{R}$ defined on some open subset Ω of some vector space V , let U be the set defined by

$$U = \{x \in \Omega \mid \varphi_i(x) \leq 0, \quad 1 \leq i \leq m\}.$$

For any $u \in U$, a constraint φ_i is said to be *active* at u if $\varphi_i(u) = 0$, else *inactive* at u if $\varphi_i(u) < 0$.

If a constraint φ_i is active at u , this corresponds to u being on a piece of the boundary of U determined by some of the equations $\varphi_i(u) = 0$; see Figure 50.6.

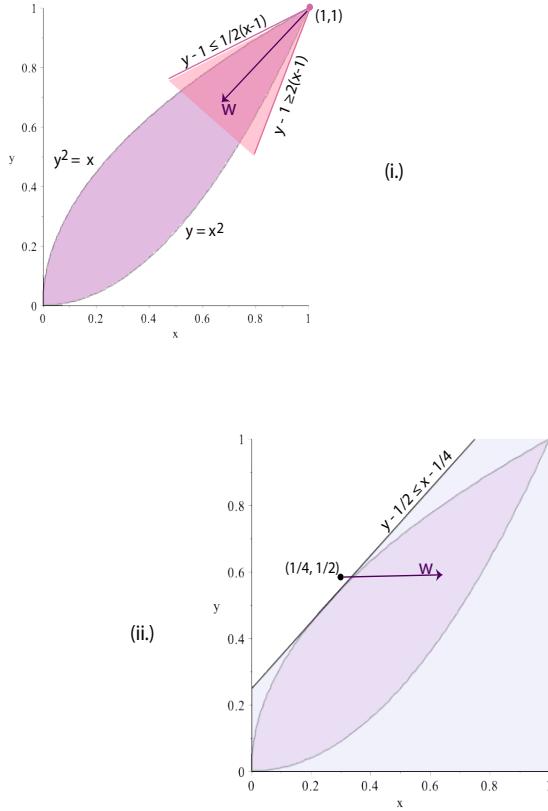

Figure 50.6: Let U be the light purple planar region which lies between the curves $y = x^2$ and $y^2 = x$. Figure (i.) illustrates the boundary point $(1, 1)$ given by the equalities $y - x^2 = 0$ and $y^2 - x = 0$. The affine translate of cone of feasible directions, $C(1, 1)$, is illustrated by the pink triangle whose sides are the tangent lines to the boundary curves. Figure (ii.) illustrates the boundary point $(1/4, 1/2)$ given by the equality $y^2 - x = 0$. The affine translate of $C(1/4, 1/2)$ is the lilac half space bounded by the tangent line to $y^2 = x$ through $(1/4, 1/2)$.

Definition 50.4. For any $u \in U$, with

$$U = \{x \in \Omega \mid \varphi_i(x) \leq 0, 1 \leq i \leq m\},$$

we define $I(u)$ as the set of indices

$$I(u) = \{i \in \{1, \dots, m\} \mid \varphi_i(u) = 0\}$$

where the constraints are active. We define the set $C^*(u)$ as

$$C^*(u) = \{v \in V \mid (\varphi'_i)_u(v) \leq 0, i \in I(u)\}.$$

Since each $(\varphi'_i)_u$ is a linear form, the subset

$$C^*(u) = \{v \in V \mid (\varphi'_i)_u(v) \leq 0, i \in I(u)\}$$

is the intersection of half spaces passing through the origin, so it is a convex set, and obviously it is a cone. If $I(u) = \emptyset$, then $C^*(u) = V$.

The special kinds of \mathcal{H} -polyhedra of the form $C^*(u)$ cut out by hyperplanes through the origin are called \mathcal{H} -cones. It can be shown that every \mathcal{H} -cone is a polyhedral cone (also called a \mathcal{V} -cone), and conversely. The proof is nontrivial; see Gallier [73] and Ziegler [195].

We will prove shortly that we always have the inclusion

$$C(u) \subseteq C^*(u).$$

However, the inclusion can be strict, as in Example 50.1. Indeed for $u = (0, 0)$ we have $I(0, 0) = \{1, 2\}$ and since

$$(\varphi'_1)_{(u_1, u_2)} = (-1 \ -1), \quad (\varphi'_2)_{(u_1, u_2)} = (3u_1^2 + u_2^2 - 2u_1 \ 2u_1 u_2 + 2u_2),$$

we have $(\varphi'_2)_{(0,0)} = (0 \ 0)$, and thus $C^*(0) = \{(u_1, u_2) \in \mathbb{R}^2 \mid u_1 + u_2 \geq 0\}$ as illustrated in Figure 50.7.

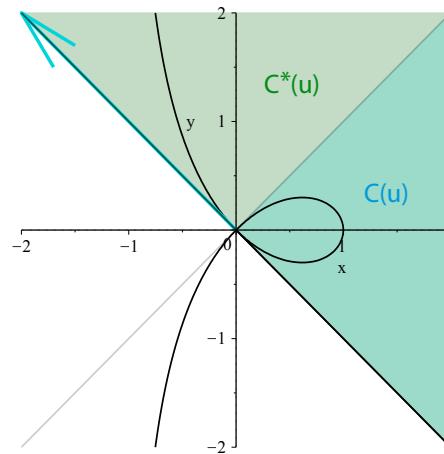

Figure 50.7: For $u = (0, 0)$, $C^*(u)$ is the sea green half space given by $u_1 + u_2 \geq 0$. This half space strictly contains $C(u)$, namely the union of the turquoise triangular cone and the directional ray $(-1, 1)$.

The conditions stated in the following definition are sufficient conditions that imply that $C(u) = C^*(u)$, as we will prove next.

Definition 50.5. For any $u \in U$, with

$$U = \{x \in \Omega \mid \varphi_i(x) \leq 0, \ 1 \leq i \leq m\},$$

if the functions φ_i are differentiable at u (in fact, we only this for $i \in I(u)$), we say that the constraints are *qualified* at u if the following conditions hold:

- (a) Either the constraints φ_i are affine for all $i \in I(u)$, or
- (b) There is some nonzero vector $w \in V$ such that the following conditions hold for all $i \in I(u)$:
 - (i) $(\varphi'_i)_u(w) \leq 0$.
 - (ii) If φ_i is not affine, then $(\varphi'_i)_u(w) < 0$.

Condition (b)(ii) implies that u is not a critical point of φ_i for every $i \in I(u)$, so there is no singularity at u in the zero locus of φ_i . Intuitively, if the constraints are qualified at u then the boundary of U near u behaves “nicely.”

The boundary points illustrated in Figure 50.6 are qualified. Observe that $U = \{x \in \mathbb{R}^2 \mid \varphi_1(x, y) = y^2 - x \leq 0, \varphi_2(x, y) = x^2 - y \leq 0\}$. For $u = (1, 1)$, $I(u) = \{1, 2\}$, $(\varphi'_1)_{(1,1)} = (-1 \ 2)$, $(\varphi'_2)_{(1,1)} = (2 \ -1)$, and $w = (-1, -1)$ ensures that $(\varphi'_1)_{(1,1)}$ and $(\varphi'_2)_{(1,1)}$ satisfy Condition (b) of Definition 50.5. For $u = (1/4, 1/2)$, $I(u) = \{1\}$, $(\varphi'_1)_{(1,1)} = (-1 \ 1)$, and $w = (1, 0)$ will satisfy Condition (b).

In Example 50.1, the constraint $\varphi_2(u_1, u_2) = 0$ is not qualified at the origin because $(\varphi'_2)_{(0,0)} = (0, 0)$; in fact, the origin is a self-intersection. In the example below, the origin is also a singular point, but for a different reason.

Example 50.2. Consider the region $U \subseteq \mathbb{R}^2$ determined by the two curves given by

$$\begin{aligned}\varphi_1(u_1, u_2) &= u_2 - \max(0, u_1^3) \\ \varphi_2(u_1, u_2) &= u_1^4 - u_2.\end{aligned}$$

We have $I(0, 0) = \{1, 2\}$, and since $(\varphi_1)'_{(0,0)}(w_1, w_2) = (0 \ 1) \begin{pmatrix} w_1 \\ w_2 \end{pmatrix} = w_2$ and $(\varphi'_2)_{(0,0)}(w_1, w_2) = (0 \ -1) \begin{pmatrix} w_1 \\ w_2 \end{pmatrix} = -w_2$, we have $C^*(0) = \{(u_1, u_2) \in \mathbb{R}^2 \mid u_2 = 0\}$, but the constraints are not qualified at $(0, 0)$ since it is impossible to have simultaneously $(\varphi'_1)_{(0,0)}(w_1, w_2) < 0$ and $(\varphi'_2)_{(0,0)}(w_1, w_2) < 0$, so in fact $C(0) = \{(u_1, u_2) \in \mathbb{R}^2 \mid u_1 \geq 0, u_2 = 0\}$ is strictly contained in $C^*(0)$; see Figure 50.8.

Proposition 50.2. Let u be any point of the set

$$U = \{x \in \Omega \mid \varphi_i(x) \leq 0, 1 \leq i \leq m\},$$

where Ω is an open subset of the normed vector space V , and assume that the functions φ_i are differentiable at u (in fact, we only this for $i \in I(u)$). Then the following facts hold:

- (1) The cone $C(u)$ of feasible directions at u is contained in the convex cone $C^*(u)$; that is,

$$C(u) \subseteq C^*(u) = \{v \in V \mid (\varphi'_i)_u(v) \leq 0, i \in I(u)\}.$$

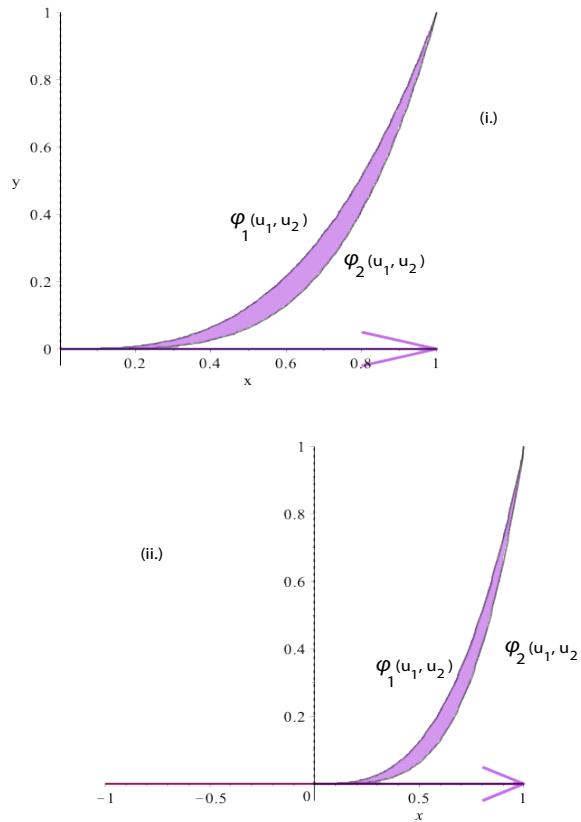

Figure 50.8: Figures (i.) and (ii.) illustrate the purple moon shaped region associated with Example 50.2. Figure (i.) also illustrates $C(0)$, the cone of feasible directions, while Figure (ii.) illustrates the strict containment of $C(0)$ in $C^*(0)$.

(2) If the constraints are qualified at u (and the functions φ_i are continuous at u for all $i \notin I(u)$ if we only assume φ_i differentiable at u for all $i \in I(u)$), then

$$C(u) = C^*(u).$$

Proof. (1) For every $i \in I(u)$, since $\varphi_i(v) \leq 0$ for all $v \in U$ and $\varphi_i(u) = 0$, the function $-\varphi_i$ has a local minimum at u with respect to U , so by Proposition 50.1(2), we have

$$(-\varphi'_i)_u(v) \geq 0 \quad \text{for all } v \in C(u),$$

which is equivalent to $(\varphi'_i)_u(v) \leq 0$ for all $v \in C(u)$ and for all $i \in I(u)$, that is, $u \in C^*(u)$.

(2)(a) First, let us assume that φ_i is affine for every $i \in I(u)$. Recall that φ_i must be given by $\varphi_i(v) = h_i(v) + c_i$ for all $v \in V$, where h_i is a linear form and $c_i \in \mathbb{R}$. Since the derivative of a linear map at any point is itself,

$$(\varphi'_i)_u(v) = h_i(v) \quad \text{for all } v \in V.$$

Pick any nonzero $w \in C^*(u)$, which means that $(\varphi'_i)_u(w) \leq 0$ for all $i \in I(u)$. For any sequence $(\epsilon_k)_{k \geq 0}$ of reals $\epsilon_k > 0$ such that $\lim_{k \rightarrow \infty} \epsilon_k = 0$, let $(u_k)_{k \geq 0}$ be the sequence of vectors in V given by

$$u_k = u + \epsilon_k w.$$

We have $u_k - u = \epsilon_k w \neq 0$ for all $k \geq 0$ and $\lim_{k \rightarrow \infty} u_k = u$. Furthermore, since the functions φ_i are continuous for all $i \notin I$, we have

$$0 > \varphi_i(u) = \lim_{k \rightarrow \infty} \varphi_i(u_k),$$

and since φ_i is affine and $\varphi_i(u) = 0$ for all $i \in I$, we have $\varphi_i(u) = h_i(u) + c_i = 0$, so

$$\varphi_i(u_k) = h_i(u_k) + c_i = h_i(u_k) - h_i(u) = h_i(u_k - u) = (\varphi'_i)_u(u_k - u) = \epsilon_k (\varphi'_i)_u(w) \leq 0, \quad (*_0)$$

which implies that $u_k \in U$ for all k large enough. Since

$$\frac{u_k - u}{\|u_k - u\|} = \frac{w}{\|w\|} \quad \text{for all } k \geq 0,$$

we conclude that $w \in C(u)$. See Figure 50.9.

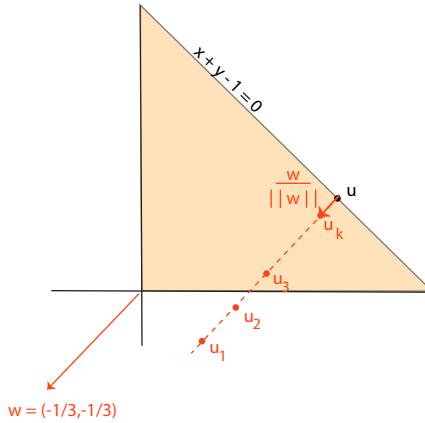

Figure 50.9: Let U be the peach triangle bounded by the lines $y = 0$, $x = 0$, and $y = -x + 1$. Let u satisfy the affine constraint $\varphi(x, y) = y + x - 1$. Since $\varphi'_{(x,y)} = (1 \ 1)$, set $w = (-1, -1)$ and approach u along the line $u + tw$.

(2)(b) Let us now consider the case where some function φ_i is not affine for some $i \in I(u)$. Let $w \neq 0$ be some vector in V such that Condition (b) of Definition 50.5 holds, namely: for all $i \in I(u)$, we have

- (i) $(\varphi'_i)_u(w) \leq 0$.
- (ii) If φ_i is not affine, then $(\varphi'_i)_u(w) < 0$.

Pick any nonzero vector $v \in C^*(u)$, which means that $(\varphi'_i)_u(v) \leq 0$ for all $i \in I(u)$, and let $\delta > 0$ be any positive real number such that $v + \delta w \neq 0$. For any sequence $(\epsilon_k)_{k \geq 0}$ of reals $\epsilon_k > 0$ such that $\lim_{k \rightarrow \infty} \epsilon_k = 0$, let $(u_k)_{k \geq 0}$ be the sequence of vectors in V given by

$$u_k = u + \epsilon_k(v + \delta w).$$

We have $u_k - u = \epsilon_k(v + \delta w) \neq 0$ for all $k \geq 0$ and $\lim_{k \rightarrow \infty} u_k = u$. Furthermore, since the functions φ_i are continuous for all $i \notin I(u)$, we have

$$0 > \varphi_i(u) = \lim_{k \rightarrow \infty} \varphi_i(u_k) \quad \text{for all } i \notin I(u). \quad (*_1)$$

Equation $(*_0)$ of the previous case shows that for all $i \in I(u)$ such that φ_i is affine, since $(\varphi'_i)_u(v) \leq 0$, $(\varphi'_i)_u(w) \leq 0$, and $\epsilon_k, \delta > 0$, we have

$$\varphi_i(u_k) = \epsilon_k((\varphi'_i)_u(v) + \delta(\varphi'_i)_u(w)) \leq 0 \quad \text{for all } i \in I(u) \text{ and } \varphi_i \text{ affine.} \quad (*_2)$$

Furthermore, since φ_i is differentiable and $\varphi_i(u) = 0$ for all $i \in I(u)$, if φ_i is not affine we have

$$\varphi_i(u_k) = \epsilon_k((\varphi'_i)_u(v) + \delta(\varphi'_i)_u(w)) + \epsilon_k \|u_k - u\| \eta_k(u_k - u)$$

with $\lim_{\|u_k - u\| \rightarrow 0} \eta_k(u_k - u) = 0$, so if we write $\alpha_k = \|u_k - u\| \eta_k(u_k - u)$, we have

$$\varphi_i(u_k) = \epsilon_k((\varphi'_i)_u(v) + \delta(\varphi'_i)_u(w) + \alpha_k)$$

with $\lim_{k \rightarrow \infty} \alpha_k = 0$, and since $(\varphi'_i)_u(v) \leq 0$, we obtain

$$\varphi_i(u_k) \leq \epsilon_k(\delta(\varphi'_i)_u(w) + \alpha_k) \quad \text{for all } i \in I(u) \text{ and } \varphi_i \text{ not affine.} \quad (*_3)$$

Equations $(*_1), (*_2), (*_3)$ show that $u_k \in U$ for k sufficiently large, where in $(*_3)$, since $(\varphi'_i)_u(w) < 0$ and $\delta > 0$, even if $\alpha_k > 0$, when $\lim_{k \rightarrow \infty} \alpha_k = 0$, we will have $\delta(\varphi'_i)_u(w) + \alpha_k < 0$ for k large enough, and thus $\epsilon_k(\delta(\varphi'_i)_u(w) + \alpha_k) < 0$ for k large enough.

Since

$$\frac{u_k - u}{\|u_k - u\|} = \frac{v + \delta w}{\|v + \delta w\|}$$

for all $k \geq 0$, we conclude that $v + \delta w \in C(u)$ for $\delta > 0$ small enough. But now the sequence $(v_n)_{n \geq 0}$ given by

$$v_n = v + \epsilon_n w$$

converges to v , and for n large enough, $v_n \in C(u)$. Since by Proposition 50.1(1), the cone $C(u)$ is closed, we conclude that $v \in C(u)$. See Figure 50.10.

In all cases, we proved that $C^*(u) \subseteq C(u)$, as claimed. \square

In the case of m affine constraints $a_i x \leq b_i$, for some linear forms a_i and some $b_i \in \mathbb{R}$, for any point $u \in \mathbb{R}^n$ such that $a_i u = b_i$ for all $i \in I(u)$, the cone $C(u)$ consists of all $v \in \mathbb{R}^n$ such that $a_i v \leq 0$, so $u + C(u)$ consists of all points $u + v$ such that

$$a_i(u + v) \leq b_i \quad \text{for all } i \in I(u),$$

which is the cone cut out by the hyperplanes determining some face of the polyhedron defined by the m constraints $a_i x \leq b_i$.

We are now ready to prove one of the most important results of nonlinear optimization.

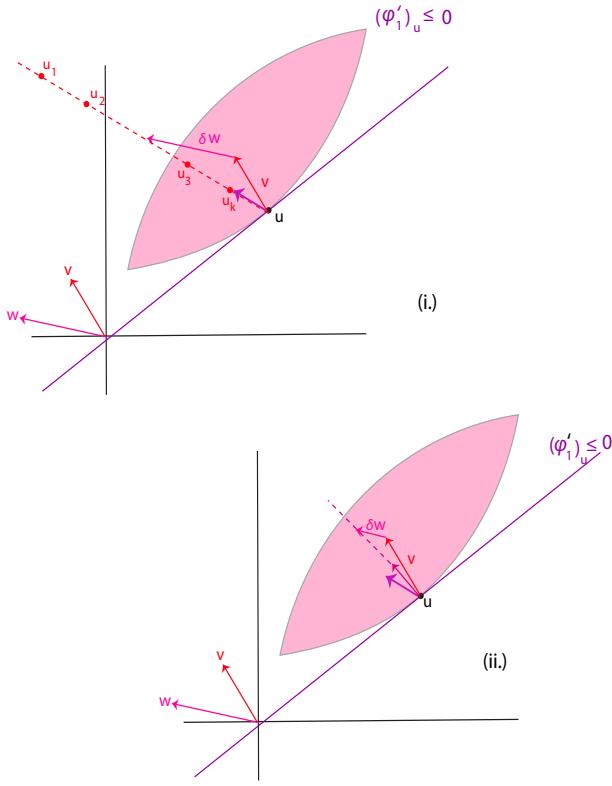

Figure 50.10: Let U be the pink lounge in \mathbb{R}^2 . Let u satisfy the non-affine constraint $\varphi_1(u)$. Choose vectors v and w in the half space $(\varphi'_1)_u \leq 0$. Figure (i.) approaches u along the line $u + t(\delta w + v)$ and shows that $v + \delta w \in C(u)$ for fixed δ . Figure (ii.) varies δ in order that the purple vectors approach v as $\delta \rightarrow \infty$.

50.3 The Karush–Kuhn–Tucker Conditions

If the domain U is defined by inequality constraints satisfying mild differentiability conditions and if the constraints at u are qualified, then there is a necessary condition for the function J to have a local minimum at $u \in U$ involving generalized Lagrange multipliers. The proof uses a version of Farkas lemma. In fact, the necessary condition stated next holds for infinite-dimensional vector spaces because there a version of Farkas lemma holding for *real* Hilbert spaces, but we will content ourselves with the version holding for finite dimensional normed vector spaces. For the more general version, see Theorem 48.12 (or Ciarlet [41], Chapter 9).

We will be using the following version of Farkas lemma.

Proposition 50.3. (*Farkas Lemma, Version I*) *Let A be a real $m \times n$ matrix and let $b \in \mathbb{R}^m$ be any vector. The linear system $Ax = b$ has no solution $x \geq 0$ iff there is some nonzero*

linear form $y \in (\mathbb{R}^m)^*$ such that $yA \geq 0_n^\top$ and $yb < 0$.

We will use the version of Farkas lemma obtained by taking a contrapositive, namely: *if $yA \geq 0_n^\top$ implies $yb \geq 0$ for all linear forms $y \in (\mathbb{R}^m)^*$, then the linear system $Ax = b$ has some solution $x \geq 0$.*

Actually, it is more convenient to use a version of Farkas lemma applying to a Euclidean vector space (with an inner product denoted $\langle -, - \rangle$). This version also applies to an infinite dimensional real Hilbert space; see Theorem 48.12. Recall that in a Euclidean space V the inner product induces an isomorphism between V and V' , the space of continuous linear forms on V . In our case, we need the isomorphism \sharp from V' to V defined such that for every linear form $\omega \in V'$, the vector $\omega^\sharp \in V$ is uniquely defined by the equation

$$\omega(v) = \langle v, \omega^\sharp \rangle \quad \text{for all } v \in V.$$

In \mathbb{R}^n , the isomorphism between \mathbb{R}^n and $(\mathbb{R}^n)^*$ amounts to *transposition*: if $y \in (\mathbb{R}^n)^*$ is a linear form and $v \in \mathbb{R}^n$ is a vector, then

$$yv = v^\top y^\top.$$

The version of the Farkas–Minkowski lemma in term of an inner product is as follows.

Proposition 50.4. (*Farkas–Minkowski*) *Let V be a Euclidean space of finite dimension with inner product $\langle -, - \rangle$ (more generally, a Hilbert space). For any finite family (a_1, \dots, a_m) of m vectors $a_i \in V$ and any vector $b \in V$, for any $v \in V$,*

$$\text{if } \langle a_i, v \rangle \geq 0 \text{ for } i = 1, \dots, m \text{ implies that } \langle b, v \rangle \geq 0,$$

then there exist $\lambda_1, \dots, \lambda_m \in \mathbb{R}$ such that

$$\lambda_i \geq 0 \text{ for } i = 1, \dots, m, \text{ and } b = \sum_{i=1}^m \lambda_i a_i,$$

that is, b belong to the polyhedral cone $\text{cone}(a_1, \dots, a_m)$.

Proposition 50.4 is the special case of Theorem 48.12 which holds for real Hilbert spaces.

We can now prove the following theorem.

Theorem 50.5. *Let $\varphi_i: \Omega \rightarrow \mathbb{R}$ be m constraints defined on some open subset Ω of a finite-dimensional Euclidean vector space V (more generally, a real Hilbert space V), let $J: \Omega \rightarrow \mathbb{R}$ be some function, and let U be given by*

$$U = \{x \in \Omega \mid \varphi_i(x) \leq 0, 1 \leq i \leq m\}.$$

For any $u \in U$, let

$$I(u) = \{i \in \{1, \dots, m\} \mid \varphi_i(u) = 0\},$$

and assume that the functions φ_i are differentiable at u for all $i \in I(u)$ and continuous at u for all $i \notin I(u)$. If J is differentiable at u , has a local minimum at u with respect to U , and if the constraints are qualified at u , then there exist some scalars $\lambda_i(u) \in \mathbb{R}$ for all $i \in I(u)$, such that

$$J'_u + \sum_{i \in I(u)} \lambda_i(u)(\varphi'_i)_u = 0, \quad \text{and} \quad \lambda_i(u) \geq 0 \text{ for all } i \in I(u).$$

The above conditions are called the Karush–Kuhn–Tucker optimality conditions. Equivalently, in terms of gradients, the above conditions are expressed as

$$\nabla J_u + \sum_{i \in I(u)} \lambda_i(u) \nabla(\varphi_i)_u = 0, \quad \text{and} \quad \lambda_i(u) \geq 0 \text{ for all } i \in I(u).$$

Proof. By Proposition 50.1(2), we have

$$J'_u(w) \geq 0 \quad \text{for all } w \in C(u), \tag{*_1}$$

and by Proposition 50.2(2), we have $C(u) = C^*(u)$, where

$$C^*(u) = \{v \in V \mid (\varphi'_i)_u(v) \leq 0, \quad i \in I(u)\}, \tag{*_2}$$

so $(*_1)$ can be expressed as: for all $w \in V$,

$$\text{if } w \in C^*(u) \text{ then } J'_u(w) \geq 0,$$

or

$$\text{if } -(\varphi'_i)_u(w) \geq 0 \text{ for all } i \in I(u), \text{ then } J'_u(w) \geq 0. \tag{*_3}$$

Under the isomorphism \sharp , the vector $(J'_u)^\sharp$ is the gradient ∇J_u , so that

$$J'_u(w) = \langle w, \nabla J_u \rangle, \tag{*_4}$$

and the vector $((\varphi'_i)_u)^\sharp$ is the gradient $\nabla(\varphi_i)_u$, so that

$$(\varphi'_i)_u(w) = \langle w, \nabla(\varphi_i)_u \rangle. \tag{*_5}$$

Using Equations $(*_4)$ and $(*_5)$, Equation $(*_3)$ can be written as: for all $w \in V$,

$$\text{if } \langle w, -\nabla(\varphi_i)_u \rangle \geq 0 \text{ for all } i \in I(u), \text{ then } \langle w, \nabla J_u \rangle \geq 0. \tag{*_6}$$

By the Farkas–Minkowski proposition (Proposition 50.4), there exist some scalars $\lambda_i(u)$ for all $i \in I(u)$, such that $\lambda_i(u) \geq 0$ and

$$\nabla J_u = \sum_{i \in I(u)} \lambda_i(u) (-\nabla(\varphi_i)_u),$$

that is

$$\nabla J_u + \sum_{i \in I(u)} \lambda_i(u) \nabla(\varphi_i)_u = 0,$$

and using the inverse of the isomorphism \sharp (which is linear), we get

$$J'_u + \sum_{i \in I(u)} \lambda_i(u)(\varphi'_i)_u = 0,$$

as claimed. \square

Since the constraints are inequalities of the form $\varphi_i(x) \leq 0$, there is a way of expressing the Karush–Kuhn–Tucker optimality conditions, often abbreviated as *KKT conditions*, in a way that does not refer explicitly to the index set $I(u)$:

$$J'_u + \sum_{i=1}^m \lambda_i(u)(\varphi'_i)_u = 0, \quad (\text{KKT}_1)$$

and

$$\sum_{i=1}^m \lambda_i(u)\varphi_i(u) = 0, \quad \lambda_i(u) \geq 0, \quad i = 1, \dots, m. \quad (\text{KKT}_2)$$

Indeed, if we have the strict inequality $\varphi_i(u) < 0$ (the constraint φ_i is inactive at u), since all the terms $\lambda_i(u)\varphi_i(u)$ are nonpositive, we must have $\lambda_i(u) = 0$; that is, we only need to consider the $\lambda_i(u)$ for all $i \in I(u)$. Yet another way to express the conditions in (KKT₂) is

$$\lambda_i(u)\varphi_i(u) = 0, \quad \lambda_i(u) \geq 0, \quad i = 1, \dots, m. \quad (\text{KKT}'_2)$$

In other words, for any $i \in \{1, \dots, m\}$, if $\varphi_i(u) < 0$, then $\lambda_i(u) = 0$; that is,

- *if the constraint φ_i is inactive at u , then $\lambda_i(u) = 0$.*

By contrapositive, if $\lambda_i(u) \neq 0$, then $\varphi_i(u) = 0$; that is,

- *if $\lambda_i(u) \neq 0$, then the constraint φ_i is active at u .*

The conditions in (KKT'₂) are referred to as *complementary slackness* conditions.

The scalars $\lambda_i(u)$ are often called *generalized Lagrange multipliers*. If $V = \mathbb{R}^n$, the necessary conditions of Theorem 50.5 are expressed as the following system of equations and inequalities in the unknowns $(u_1, \dots, u_n) \in \mathbb{R}^n$ and $(\lambda_1, \dots, \lambda_m) \in \mathbb{R}_+^m$:

$$\begin{aligned} \frac{\partial J}{\partial x_1}(u) + \lambda_1 \frac{\partial \varphi_1}{\partial x_1}(u) + \cdots + \lambda_m \frac{\partial \varphi_m}{\partial x_1}(u) &= 0 \\ &\vdots && \vdots \\ \frac{\partial J}{\partial x_n}(u) + \lambda_1 \frac{\partial \varphi_n}{\partial x_1}(u) + \cdots + \lambda_m \frac{\partial \varphi_m}{\partial x_n}(u) &= 0 \\ \lambda_1 \varphi_1(u) + \cdots + \lambda_m \varphi_m(u) &= 0 \\ \varphi_1(u) &\leq 0 \\ &\vdots && \vdots \\ \varphi_m(u) &\leq 0 \\ \lambda_1, \dots, \lambda_m &\geq 0. \end{aligned}$$

Example 50.3. Let J , φ_1 and φ_2 be the functions defined on \mathbb{R} by

$$\begin{aligned} J(x) &= x \\ \varphi_1(x) &= -x \\ \varphi_2(x) &= x - 1. \end{aligned}$$

In this case

$$U = \{x \in \mathbb{R} \mid -x \leq 0, x - 1 \leq 0\} = [0, 1].$$

Since the constraints are affine, they are automatically qualified for any $u \in [0, 1]$. The system of equations and inequalities shown above becomes

$$\begin{aligned} 1 - \lambda_1 + \lambda_2 &= 0 \\ -\lambda_1 x + \lambda_2(x - 1) &= 0 \\ -x &\leq 0 \\ x - 1 &\leq 0 \\ \lambda_1, \lambda_2 &\geq 0. \end{aligned}$$

The first equality implies that $\lambda_1 = 1 + \lambda_2$. The second equality then becomes

$$-(1 + \lambda_2)x + \lambda_2(x - 1) = 0,$$

which implies that $\lambda_2 = -x$. Since $0 \leq x \leq 1$, or equivalently $-1 \leq -x \leq 0$, and $\lambda_2 \geq 0$, we conclude that $\lambda_2 = 0$ and $\lambda_1 = 1$ is the solution associated with $x = 0$, the minimum of $J(x) = x$ over $[0, 1]$. Observe that the case $x = 1$ corresponds to the maximum and not a minimum of $J(x) = x$ over $[0, 1]$.

Remark: Unless the linear forms $(\varphi'_i)_u$ for $i \in I(u)$ are linearly independent, the $\lambda_i(u)$ are generally not unique. Also, if $I(u) = \emptyset$, then the KKT conditions reduce to $J'_u = 0$. This is not surprising because in this case u belongs to the relative interior of U .

If the constraints are all affine equality constraints, then the KKT conditions are a bit simpler. We will consider this case shortly.

The conditions for the qualification of nonaffine constraints are hard (if not impossible) to use in practice, because they depend on $u \in U$ and on the derivatives $(\varphi'_i)_u$. Thus it is desirable to find simpler conditions. Fortunately, this is possible if the nonaffine functions φ_i are *convex*.

Definition 50.6. Let $U \subseteq \Omega \subseteq V$ be given by

$$U = \{x \in \Omega \mid \varphi_i(x) \leq 0, 1 \leq i \leq m\},$$

where Ω is an open subset of the Euclidean vector space V . If the functions $\varphi_i: \Omega \rightarrow \mathbb{R}$ are convex, we say that the constraints are *qualified* if the following conditions hold:

- (a) Either the constraints φ_i are affine for all $i = 1, \dots, m$ and $U \neq \emptyset$, or
- (b) There is some vector $v \in \Omega$ such that the following conditions hold for $i = 1, \dots, m$:
 - (i) $\varphi_i(v) \leq 0$.
 - (ii) If φ_i is not affine, then $\varphi_i(v) < 0$.

The above qualification conditions are known as *Slater's conditions*.

Condition (b)(i) also implies that U has nonempty relative interior. If Ω is convex, then U is also convex. This is because for all $u, v \in \Omega$, if $u \in U$ and $v \in U$, that is $\varphi_i(u) \leq 0$ and $\varphi_i(v) \leq 0$ for $i = 1, \dots, m$, since the functions φ_i are convex, for all $\theta \in [0, 1]$ we have

$$\begin{aligned} \varphi_i((1 - \theta)u + \theta v) &\leq (1 - \theta)\varphi_i(u) + \theta\varphi_i(v) && \text{since } \varphi_i \text{ is convex} \\ &\leq 0 && \text{since } 1 - \theta \geq 0, \theta \geq 0, \varphi_i(u) \leq 0, \varphi_i(v) \leq 0, \end{aligned}$$

and any intersection of convex sets is convex.

 It is important to observe that a *nonaffine equality constraint* $\varphi_i(u) = 0$ is *never* qualified.

Indeed, $\varphi_i(u) = 0$ is equivalent to $\varphi_i(u) \leq 0$ and $-\varphi_i(u) \leq 0$, so if these constraints are qualified and if φ_i is not affine then there is some nonzero vector $v \in \Omega$ such that both $\varphi_i(v) < 0$ and $-\varphi_i(v) < 0$, which is impossible. For this reason, *equality constraints are often assumed to be affine*.

The following theorem yields a more flexible version of Theorem 50.5 for constraints given by convex functions. If in addition, the function J is also *convex*, then the KKT conditions are also a *sufficient* condition for a local minimum.

Theorem 50.6. *Let $\varphi_i: \Omega \rightarrow \mathbb{R}$ be m convex constraints defined on some open convex subset Ω of a finite-dimensional Euclidean vector space V (more generally, a real Hilbert space V), let $J: \Omega \rightarrow \mathbb{R}$ be some function, let U be given by*

$$U = \{x \in \Omega \mid \varphi_i(x) \leq 0, 1 \leq i \leq m\},$$

and let $u \in U$ be any point such that the functions φ_i and J are differentiable at u .

- (1) *If J has a local minimum at u with respect to U , and if the constraints are qualified, then there exist some scalars $\lambda_i(u) \in \mathbb{R}$, such that the KKT condition hold:*

$$J'_u + \sum_{i=1}^m \lambda_i(u)(\varphi'_i)_u = 0$$

and

$$\sum_{i=1}^m \lambda_i(u)\varphi_i(u) = 0, \quad \lambda_i(u) \geq 0, \quad i = 1, \dots, m.$$

Equivalently, in terms of gradients, the above conditions are expressed as

$$\nabla J_u + \sum_{i=1}^m \lambda_i(u) \nabla(\varphi_i)_u = 0,$$

and

$$\sum_{i=1}^m \lambda_i(u) \varphi_i(u) = 0, \quad \lambda_i(u) \geq 0, \quad i = 1, \dots, m.$$

- (2) Conversely, if the restriction of J to U is convex and if there exist scalars $(\lambda_1, \dots, \lambda_m) \in \mathbb{R}_+^m$ such that the KKT conditions hold, then the function J has a (global) minimum at u with respect to U .

Proof. (1) It suffices to prove that if the convex constraints are qualified according to Definition 50.6, then they are qualified according to Definition 50.5, since in this case we can apply Theorem 50.5.

If $v \in \Omega$ is a vector such that Condition (b) of Definition 50.6 holds and if $v \neq u$, for any $i \in I(u)$, since $\varphi_i(u) = 0$ and since φ_i is convex, by Proposition 40.11(1),

$$\varphi_i(v) \geq \varphi_i(u) + (\varphi'_i)_u(v - u) = (\varphi'_i)_u(v - u),$$

so if we let $w = v - u$ then

$$(\varphi'_i)_u(w) \leq \varphi_i(v),$$

which shows that the nonaffine constraints φ_i for $i \in I(u)$ are qualified according to Definition 50.5, by Condition (b) of Definition 50.6.

If $v = u$, then the constraints φ_i for which $\varphi_i(u) = 0$ must be affine (otherwise, Condition (b)(ii) of Definition 50.6 would be false), and in this case we can pick $w = 0$.

(2) Let v be any arbitrary point in the convex subset U . Since $\varphi_i(v) \leq 0$ and $\lambda_i \geq 0$ for $i = 1, \dots, m$, we have $\sum_{i=1}^m \lambda_i \varphi_i(v) \leq 0$, and using the fact that

$$\sum_{i=1}^m \lambda_i(u) \varphi_i(u) = 0, \quad \lambda_i(u) \geq 0, \quad i = 1, \dots, m,$$

we have $\lambda_i = 0$ if $i \notin I(u)$ and $\varphi_i(u) = 0$ if $i \in I(u)$, so we have

$$\begin{aligned} J(u) &\leq J(u) - \sum_{i=1}^m \lambda_i \varphi_i(v) \\ &\leq J(u) - \sum_{i \in I(u)} \lambda_i (\varphi_i(v) - \varphi_i(u)) & \lambda_i = 0 \text{ if } i \notin I(u), \varphi_i(u) = 0 \text{ if } i \in I(u) \\ &\leq J(u) - \sum_{i \in I(u)} \lambda_i (\varphi'_i)_u(v - u) & \text{(by Proposition 40.11)(1)} \\ &\leq J(u) + J'_u(v - u) & \text{(by the KKT conditions)} \\ &\leq J(v) & \text{(by Proposition 40.11)(1),} \end{aligned}$$

and this shows that u is indeed a (global) minimum of J over U . \square

It is important to note that when *both* the constraints, the domain of definition Ω , and the objective function J are *convex*, if the KKT conditions hold for some $u \in U$ and some $\lambda \in \mathbb{R}_+^m$, then Theorem 50.6 implies that J has a (global) minimum at u with respect to U , *independently* of any assumption on the qualification of the constraints.

The above theorem suggests introducing the function $L: \Omega \times \mathbb{R}_+^m \rightarrow \mathbb{R}$ given by

$$L(v, \lambda) = J(v) + \sum_{i=1}^m \lambda_i \varphi_i(v),$$

with $\lambda = (\lambda_1, \dots, \lambda_m)$. The function L is called the *Lagrangian* of the *Minimization Problem* (*P*):

$$\begin{aligned} & \text{minimize} && J(v) \\ & \text{subject to} && \varphi_i(v) \leq 0, \quad i = 1, \dots, m. \end{aligned}$$

The KKT conditions of Theorem 50.6 imply that for any $u \in U$, if the vector $\lambda = (\lambda_1, \dots, \lambda_m)$ is known and if u is a minimum of J on U , then

$$\begin{aligned} \frac{\partial L}{\partial u}(u) &= 0 \\ J(u) &= L(u, \lambda). \end{aligned}$$

The Lagrangian technique “absorbs” the constraints into the new objective function L and reduces the problem of finding a constrained minimum of the function J , to the problem of finding an unconstrained minimum of the function $L(v, \lambda)$. This is the main point of Lagrangian duality which will be treated in the next section.

A case that arises often in practice is the case where the constraints φ_i are affine. If so, the m constraints $a_i x \leq b_i$ can be expressed in matrix form as $Ax \leq b$, where A is an $m \times n$ matrix whose i th row is the row vector a_i . The KKT conditions of Theorem 50.6 yield the following corollary.

Proposition 50.7. *If U is given by*

$$U = \{x \in \Omega \mid Ax \leq b\},$$

where Ω is an open convex subset of \mathbb{R}^n and A is an $m \times n$ matrix, and if J is differentiable at u and J has a local minimum at u , then there exist some vector $\lambda \in \mathbb{R}^m$, such that

$$\begin{aligned} \nabla J_u + A^\top \lambda &= 0 \\ \lambda_i &\geq 0 \text{ and if } a_i u < b_i, \text{ then } \lambda_i = 0, \quad i = 1, \dots, m. \end{aligned}$$

If the function J is convex, then the above conditions are also sufficient for J to have a minimum at $u \in U$.

Another case of interest is the generalization of the minimization problem involving the affine constraints of a linear program in standard form, that is, equality constraints $Ax = b$ with $x \geq 0$, where A is an $m \times n$ matrix. In our formalism, this corresponds to the $2m + n$ constraints

$$\begin{aligned} a_i x - b_i &\leq 0, & i &= 1, \dots, m \\ -a_i x + b_i &\leq 0, & i &= 1, \dots, m \\ -x_j &\leq 0, & j &= 1, \dots, n. \end{aligned}$$

In matrix form, they can be expressed as

$$\begin{pmatrix} A \\ -A \\ -I_n \end{pmatrix} \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix} \leq \begin{pmatrix} b \\ -b \\ 0_n \end{pmatrix}.$$

If we introduce the generalized Lagrange multipliers λ_i^+ and λ_i^- for $i = 1, \dots, m$ and μ_j for $j = 1, \dots, n$, then the KKT conditions are

$$\nabla J_u + (A^\top \quad -A^\top \quad -I_n) \begin{pmatrix} \lambda^+ \\ \lambda^- \\ \mu \end{pmatrix} = 0_n,$$

that is,

$$\nabla J_u + A^\top \lambda^+ - A^\top \lambda^- - \mu = 0,$$

and $\lambda^+, \lambda^-, \mu \geq 0$, and if $a_i u < b_i$, then $\lambda_i^+ = 0$, if $-a_i u < -b_i$, then $\lambda_i^- = 0$, and if $-u_j < 0$, then $\mu_j = 0$. But the constraints $a_i u = b_i$ hold for $i = 1, \dots, m$, so this places no restriction on the λ_i^+ and λ_i^- , and if we write $\lambda_i = \lambda_i^+ - \lambda_i^-$, then we have

$$\nabla J_u + A^\top \lambda = \mu,$$

with $\mu_j \geq 0$, and if $u_j > 0$ then $\mu_j = 0$, for $j = 1, \dots, n$.

Thus we proved the following proposition (which is slight generalization of Proposition 8.7.2 in Matousek and Gardner [123]).

Proposition 50.8. *If U is given by*

$$U = \{x \in \Omega \mid Ax = b, x \geq 0\},$$

where Ω is an open convex subset of \mathbb{R}^n and A is an $m \times n$ matrix, and if J is differentiable at u and J has a local minimum at u , then there exist two vectors $\lambda \in \mathbb{R}^m$ and $\mu \in \mathbb{R}^n$, such that

$$\nabla J_u + A^\top \lambda = \mu,$$

with $\mu_j \geq 0$, and if $u_j > 0$ then $\mu_j = 0$, for $j = 1, \dots, n$. Equivalently, there exists a vector $\lambda \in \mathbb{R}^m$ such that

$$(\nabla J_u)_j + (A^j)^\top \lambda \quad \begin{cases} = 0 & \text{if } u_j > 0 \\ \geq 0 & \text{if } u_j = 0, \end{cases}$$

where A^j is the j th column of A . If the function J is convex, then the above conditions are also sufficient for J to have a minimum at $u \in U$.

Yet another special case that arises frequently in practice is the minimization problem involving the affine equality constraints $Ax = b$, where A is an $m \times n$ matrix, with no restriction on x . Reviewing the proof of Proposition 50.8, we obtain the following proposition.

Proposition 50.9. *If U is given by*

$$U = \{x \in \Omega \mid Ax = b\},$$

where Ω is an open convex subset of \mathbb{R}^n and A is an $m \times n$ matrix, and if J is differentiable at u and J has a local minimum at u , then there exist some vector $\lambda \in \mathbb{R}^m$ such that

$$\nabla J_u + A^\top \lambda = 0.$$

Equivalently, there exists a vector $\lambda \in \mathbb{R}^m$ such that

$$(\nabla J_u)_j + (A^j)^\top \lambda = 0,$$

where A^j is the j th column of A . If the function J is convex, then the above conditions are also sufficient for J to have a minimum at $u \in U$.

Observe that in Proposition 50.9, the λ_i are just standard Lagrange multipliers, with no restriction of positivity. Thus, Proposition 50.9 is a slight generalization of Theorem 40.2 that requires A to have rank m , but in the case of equational affine constraints, this assumption is unnecessary.

Here is an application of Proposition 50.9 to the *interior point method* in linear programming.

Example 50.4. In linear programming, the interior point method using a central path uses a logarithmic barrier function to keep the solutions $x \in \mathbb{R}^n$ of the equation $Ax = b$ away from boundaries by forcing $x > 0$, which means that $x_i > 0$ for all i ; see Matousek and Gardner [123] (Section 7.2). Write

$$\mathbb{R}_{++}^n = \{x \in \mathbb{R}^n \mid x_i > 0, i = 1, \dots, n\}.$$

Observe that \mathbb{R}_{++}^n is open and convex. For any $\mu > 0$, we define the function f_μ defined on \mathbb{R}_{++}^n by

$$f_\mu(x) = c^\top x + \mu \sum_{i=1}^n \ln x_i,$$

where $c \in \mathbb{R}^n$.

We would like to find necessary conditions for f_μ to have a maximum on

$$U = \{x \in \mathbb{R}_{++}^n \mid Ax = b\},$$

or equivalently to solve the following problem:

$$\begin{aligned} & \text{maximize} && f_\mu(x) \\ & \text{subject to} && \end{aligned}$$

$$Ax = b$$

$$x > 0.$$

Since maximizing f_μ is equivalent to minimizing $-f_\mu$, by Proposition 50.9, if x is an optimal of the above problem then there is some $y \in \mathbb{R}^m$ such that

$$-\nabla f_\mu(x) + A^\top y = 0.$$

Since

$$\nabla f_\mu(x) = \begin{pmatrix} c_1 + \frac{\mu}{x_1} \\ \vdots \\ c_n + \frac{\mu}{x_n} \end{pmatrix},$$

we obtain the equation

$$c + \mu \begin{pmatrix} \frac{1}{x_1} \\ \vdots \\ \frac{1}{x_n} \end{pmatrix} = A^\top y.$$

To obtain a more convenient formulation, we define $s \in \mathbb{R}_{++}^n$ such that

$$s = \mu \begin{pmatrix} \frac{1}{x_1} \\ \vdots \\ \frac{1}{x_n} \end{pmatrix}$$

which implies that

$$(s_1 x_1 \quad \cdots \quad s_n x_n) = \mu \mathbf{1}_n^\top,$$

and we obtain the following necessary conditions for f_μ to have a maximum:

$$\begin{aligned} & Ax = b \\ & A^\top y - s = c \\ & (s_1 x_1 \quad \cdots \quad s_n x_n) = \mu \mathbf{1}_n^\top \\ & s, x > 0. \end{aligned}$$

It is not hard to show that if the primal linear program with objective function $c^\top x$ and equational constraints $Ax = b$ and the dual program with objective function $b^\top y$ and inequality constraints $A^\top y \geq c$ have interior feasible points x and y , which means that $x > 0$ and $s > 0$ (where $s = A^\top y - c$), then the above system of equations has a unique solution such that x is the unique maximizer of f_μ on U ; see Matousek and Gardner [123] (Section 7.2, Lemma 7.2.1).

A particularly important application of Proposition 50.9 is the situation where $\Omega = \mathbb{R}^n$.

50.4 Equality Constrained Minimization

In this section we consider the following Program (P):

$$\begin{aligned} &\text{minimize} && J(v) \\ &\text{subject to} && Av = b, v \in \mathbb{R}^n, \end{aligned}$$

where J is a convex differentiable function and A is an $m \times n$ matrix of rank $m < n$ (the number of equality constraints is less than the number of variables, and these constraints are independent), and $b \in \mathbb{R}^m$.

According to Proposition 50.9 (with $\Omega = \mathbb{R}^n$), Program (P) has a minimum at $x \in \mathbb{R}^n$ if and only if there exist some Lagrange multipliers $\lambda \in \mathbb{R}^m$ such that the following equations hold:

$$\begin{aligned} Ax &= b && \text{(pfeasibilty)} \\ \nabla J_x + A^\top \lambda &= 0. && \text{(dfeasibility)} \end{aligned}$$

The set of linear equations $Ax = b$ is called the *primal feasibility equations* and the set of (generally nonlinear) equations $\nabla J_x + A^\top \lambda = 0$ is called the set of *dual feasibility equations*.

In general, it is impossible to solve these equations analytically, so we have to use numerical approximation procedures, most of which are variants of Newton's method. In special cases, for example if J is a quadratic functional, the dual feasibility equations are also linear, a case that we consider in more detail.

Suppose J is a convex quadratic functional of the form

$$J(x) = \frac{1}{2}x^\top Px + q^\top x + r,$$

where P is a $n \times n$ symmetric positive semidefinite matrix, $q \in \mathbb{R}^n$ and $r \in \mathbb{R}$. In this case

$$\nabla J_x = Px + q,$$

so the feasibility equations become

$$\begin{aligned} Ax &= b \\ Px + q + A^\top \lambda &= 0, \end{aligned}$$

which in matrix form become

$$\begin{pmatrix} P & A^\top \\ A & 0 \end{pmatrix} \begin{pmatrix} x \\ \lambda \end{pmatrix} = \begin{pmatrix} -q \\ b \end{pmatrix}. \quad (\text{KKT-eq})$$

The matrix of the linear system is usually called the *KKT-matrix*. Observe that the KKT matrix was already encountered in Proposition 42.3 with a different notation; there we had $P = A^{-1}$, $A = B^\top$, $q = b$, and $b = f$.

If the KKT matrix is invertible, then its unique solution (x^*, λ^*) yields a unique minimum x^* of Problem (P) . If the KKT matrix is singular but the System (KKT-eq) is solvable, then *any solution* (x^*, λ^*) yields a minimum x^* of Problem (P) .

Proposition 50.10. *If the System (KKT-eq) is not solvable, then Program (P) is unbounded below.*

Proof. We use the fact shown in Section 30.7, that a linear system $Bx = c$ has no solution iff there is some y that $B^\top y = 0$ and $y^\top c \neq 0$. By changing y to $-y$ if necessary, we may assume that $y^\top c > 0$. We apply this fact to the linear system (KKT-eq), so B is the KKT-matrix, which is symmetric, and we obtain the condition that there exist $v \in \mathbb{R}^n$ and $\lambda \in \mathbb{R}^m$ such that

$$Pv + A^\top \lambda = 0, \quad Av = 0, \quad -q^\top v + b^\top \lambda > 0.$$

Since the $m \times n$ matrix A has rank m and $b \in \mathbb{R}^m$, the system $Ax = b$, is solvable, so for any feasible x_0 (which means that $Ax_0 = b$), since $Av = 0$, the vector $x = x_0 + tv$ is also a feasible solution for all $t \in \mathbb{R}$. Using the fact that $Pv = -A^\top \lambda$, $v^\top P = -\lambda^\top A$, $Av = 0$, $x_0^\top A^\top = b^\top$, and P is symmetric, we have

$$\begin{aligned} J(x_0 + tv) &= J(x_0) + (v^\top Px_0 + q^\top v)t + (1/2)(v^\top Pv)t^2 \\ &= J(x_0) + (x_0^\top Pv + q^\top v)t - (1/2)(\lambda^\top Av)t^2 \\ &= J(x_0) + (-x_0^\top A^\top \lambda + q^\top v)t \\ &= J(x_0) - (b^\top \lambda - q^\top v)t, \end{aligned}$$

and since $-q^\top v + b^\top \lambda > 0$, the above expression goes to $-\infty$ when t goes to $+\infty$. \square

It is obviously important to have criteria to decide whether the KKT-matrix is invertible. There are indeed such criteria, as pointed in Boyd and Vandenberghe [29] (Chapter 10, Exercise 10.1).

Proposition 50.11. *The invertibility of the KKT-matrix*

$$\begin{pmatrix} P & A^\top \\ A & 0 \end{pmatrix}$$

is equivalent to the following conditions:

- (1) For all $x \in \mathbb{R}^n$, if $Ax = 0$ with $x \neq 0$, then $x^\top Px > 0$; that is, P is positive definite on the kernel of A .
- (2) The kernels of A and P only have 0 in common ($(\text{Ker } A) \cap (\text{Ker } P) = \{0\}$).
- (3) There is some $n \times (n-m)$ matrix F such that $\text{Im}(F) = \text{Ker}(A)$ and $F^\top PF$ is symmetric positive definite.
- (4) There is some symmetric positive semidefinite matrix Q such that $P + A^\top QA$ is symmetric positive definite. In fact, $Q = I$ works.

Proof sketch. Recall from Proposition 6.19 that a square matrix B is invertible iff its kernel is reduced to $\{0\}$; equivalently, for all x , if $Bx = 0$, then $x = 0$. Assume that Condition (1) holds. We have

$$\begin{pmatrix} P & A^\top \\ A & 0 \end{pmatrix} \begin{pmatrix} v \\ w \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

iff

$$Pv + A^\top w = 0, \quad Av = 0. \tag{*}$$

We deduce that

$$v^\top Pv + v^\top A^\top w = 0,$$

and since

$$v^\top A^\top w = (Av)^\top w = 0w = 0,$$

we obtain $v^\top Pv = 0$. Since Condition (1) holds, because $v \in \text{Ker } A$, we deduce that $v = 0$. Then $A^\top w = 0$, but since the $m \times n$ matrix A has rank m , the $n \times m$ matrix A^\top also has rank m , so its columns are linearly independent, and so $w = 0$. Therefore the KKT-matrix is invertible.

Conversely, assume that the KKT-matrix is invertible, yet the assumptions of Condition (1) fail. This means there is some $v \neq 0$ such that $Av = 0$ and $v^\top Pv = 0$. We claim that $Pv = 0$. This is because if P is a symmetric positive semidefinite matrix, then for any v , we have $v^\top Pv = 0$ iff $Pv = 0$.

If $Pv = 0$, then obviously $v^\top Pv = 0$, so assume the converse, namely $v^\top Pv = 0$. Since P is a symmetric positive semidefinite matrix, it can be diagonalized as

$$P = R^\top \Sigma R,$$

where R is an orthogonal matrix and Σ is a diagonal matrix

$$\Sigma = \text{diag}(\lambda_1, \dots, \lambda_s, 0, \dots, 0),$$

where s is the rank of P and $\lambda_1 \geq \dots \geq \lambda_s > 0$. Then $v^\top Pv = 0$ is equivalent to

$$v^\top R^\top \Sigma R v = 0,$$

equivalently

$$(Rv)^\top \Sigma R v = 0.$$

If we write $Rv = y$, then we have

$$0 = (Rv)^\top \Sigma R v = y^\top \Sigma y = \sum_{i=1}^s \lambda_i y_i^2,$$

and since $\lambda_i > 0$ for $i = 1, \dots, s$, this implies that $y_i = 0$ for $i = 1, \dots, s$. Consequently, $\Sigma y = \Sigma Rv = 0$, and so $Pv = R^\top \Sigma R v = 0$, as claimed. Since $v \neq 0$, the vector $(v, 0)$ is a nontrivial solution of Equations (*), a contradiction of the invertibility assumption of the KKT-matrix.

Observe that we proved that $Av = 0$ and $Pv = 0$ iff $Av = 0$ and $v^\top Pv = 0$, so we easily obtain the fact that Condition (2) is equivalent to the invertibility of the KKT-matrix. Parts (3) and (4) are left as an exercise. \square

In particular, if P is positive definite, then Proposition 50.11(4) applies, as we already know from Proposition 42.3. In this case, we can solve for x by elimination. We get

$$x = -P^{-1}(A^\top \lambda + q), \quad \text{where } \lambda = -(AP^{-1}A^\top)^{-1}(b + AP^{-1}q).$$

In practice, we do not invert P and $AP^{-1}A^\top$. Instead, we solve the linear systems

$$\begin{aligned} Pz &= q \\ PE &= A^\top \\ (AE)\lambda &= -(b + Az) \\ Px &= -(A^\top \lambda + q). \end{aligned}$$

Observe that $(AP^{-1}A^\top)^{-1}$ is the Schur complement of P in the KKT matrix.

Since the KKT-matrix is symmetric, if it is invertible, we can convert it to LDL^\top form using Proposition 8.6. This method is only practical when the problem is small or when A and P are sparse.

If the KKT-matrix is invertible but P is not, then we can use a trick involving Proposition 50.11. We find a symmetric positive semidefinite matrix Q such that $P + A^\top Q A$ is symmetric

positive definite, and since a solution (v, w) of the KKT-system should have $Av = b$, we also have $A^\top QAv = A^\top Qb$, so the KKT-system is equivalent to

$$\begin{pmatrix} P + A^\top QA & A^\top \\ A & 0 \end{pmatrix} \begin{pmatrix} v \\ w \end{pmatrix} = \begin{pmatrix} -q + A^\top Qb \\ b \end{pmatrix},$$

and since $P + A^\top QA$ is symmetric positive definite, we can solve this system by elimination.

Another way to solve Problem (P) is to use variants of Newton's method as described in Section 49.9 dealing with equality constraints. Such methods are discussed extensively in Boyd and Vandenberghe [29] (Chapter 10, Sections 10.2-10.4).

There are two variants of this method:

- (1) The first method, called *feasible start Newton method*, assumes that the starting point u_0 is feasible, which means that $Au_0 = b$. The Newton step d_{nt} is a feasible direction, which means that $Ad_{\text{nt}} = 0$.
- (2) The second method, called *infeasible start Newton method*, does *not* assume that the starting point u_0 is feasible, which means that $Au_0 = b$ may not hold. This method is a little more complicated than the other method.

We only briefly discuss the feasible start Newton method, leaving it to the reader to consult Boyd and Vandenberghe [29] (Chapter 10, Section 10.3) for a discussion of the infeasible start Newton method.

The Newton step d_{nt} is the solution of the linear system

$$\begin{pmatrix} \nabla^2 J(x) & A^\top \\ A & 0 \end{pmatrix} \begin{pmatrix} d_{\text{nt}} \\ w \end{pmatrix} = \begin{pmatrix} -\nabla J_x \\ 0 \end{pmatrix}.$$

The Newton decrement $\lambda(x)$ is defined as in Section 49.9 as

$$\lambda(x) = (d_{\text{nt}}^\top \nabla^2 J(x) d_{\text{nt}})^{1/2} = ((\nabla J_x)^\top (\nabla^2 J(x))^{-1} \nabla J_x)^{1/2}.$$

Newton's method with equality constraints (with feasible start) consists of the following steps: Given a starting point $u_0 \in \text{dom}(J)$ with $Au_0 = b$, and a tolerance $\epsilon > 0$ do:

repeat

- (1) Compute the Newton step and decrement
 $d_{\text{nt},k} = -(\nabla^2 J(u_k))^{-1} \nabla J_{u_k}$ and $\lambda(u_k)^2 = (\nabla J_{u_k})^\top (\nabla^2 J(u_k))^{-1} \nabla J_{u_k}$.
- (2) Stopping criterion. **quit** if $\lambda(u_k)^2/2 \leq \epsilon$.
- (3) Line Search. Perform an exact or backtracking line search to find ρ_k .
- (4) Update. $u_{k+1} = u_k + \rho_k d_{\text{nt},k}$.

Newton's method requires that the KKT-matrix be invertible. Under some mild assumptions, Newton's method (with feasible start) converges; see Boyd and Vandenberghe [29] (Chapter 10, Section 10.2.4).

We now give an example illustrating Proposition 50.7, the *Support Vector Machine* (abbreviated as *SVM*).

50.5 Hard Margin Support Vector Machine; Version I

In this section we describe the following *classification problem*, or perhaps more accurately, *separation problem* (into two classes). Suppose we have two nonempty disjoint finite sets of p blue points $\{u_i\}_{i=1}^p$ and q red points $\{v_j\}_{j=1}^q$ in \mathbb{R}^n (for simplicity, you may assume that these points are in the plane, that is, $n = 2$). Our goal is to find a hyperplane H of equation $w^\top x - b = 0$ (where $w \in \mathbb{R}^n$ is a nonzero vector and $b \in \mathbb{R}$), such that all the blue points u_i are in one of the two open half-spaces determined by H , and all the red points v_j are in the other open half-space determined by H ; see Figure 50.11.

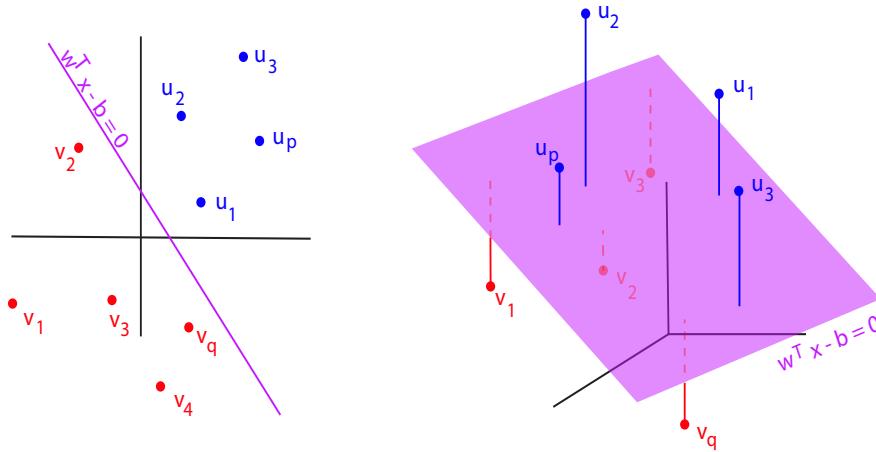

Figure 50.11: Two examples of the SVM separation problem. The left figure is SVM in \mathbb{R}^2 , while the right figure is SVM in \mathbb{R}^3 .

Without loss of generality, we may assume that

$$\begin{aligned} w^\top u_i - b &> 0 && \text{for } i = 1, \dots, p \\ w^\top v_j - b &< 0 && \text{for } j = 1, \dots, q. \end{aligned}$$

Of course, separating the blue and the red points may be impossible, as we see in Figure 50.12 for four points where the line segments (u_1, u_2) and (v_1, v_2) intersect. If a hyperplane separating the two subsets of blue and red points exists, we say that they are *linearly separable*.

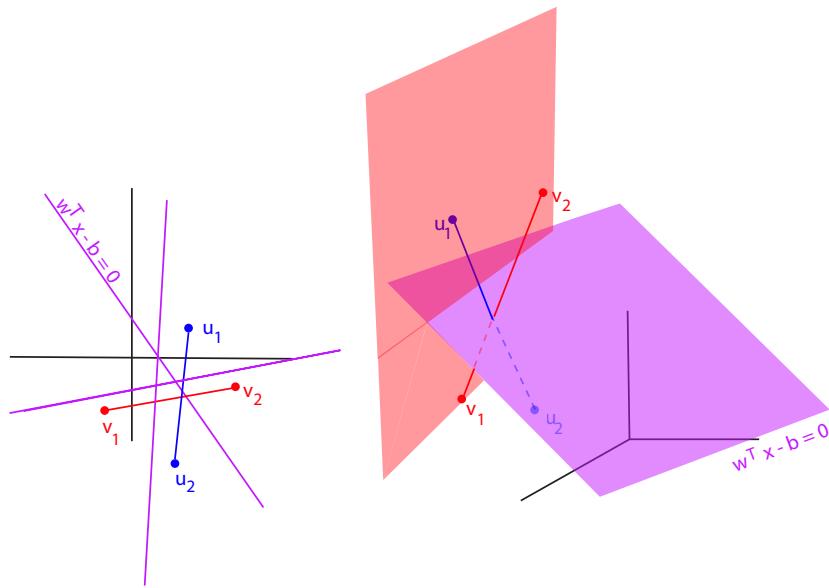

Figure 50.12: Two examples in which it is impossible to find purple hyperplanes which separate the red and blue points.

Remark: Write $m = p + q$. The reader should be aware that in machine learning the classification problem is usually defined as follows. We assign m so-called *class labels* $y_k = \pm 1$ to the data points in such a way that $y_i = +1$ for each blue point u_i , and $y_{p+j} = -1$ for each red point v_j , and we denote the m points by x_k , where $x_k = u_k$ for $k = 1, \dots, p$ and $x_k = v_{k-p}$ for $k = p+1, \dots, p+q$. Then the classification constraints can be written as

$$y_k(w^\top x_k - b) > 0 \quad \text{for } k = 1, \dots, m.$$

The set of pairs $\{(x_1, y_1), \dots, (x_m, y_m)\}$ is called a set of *training data* (or *training set*).

In the sequel, we will not use the above method, and we will stick to our two subsets of p *blue* points $\{u_i\}_{i=1}^p$ and q *red* points $\{v_j\}_{j=1}^q$.

Since there are infinitely many hyperplanes separating the two subsets (if indeed the two subsets are linearly separable), we would like to come up with a “good” criterion for choosing such a hyperplane.

The idea that was advocated by Vapnik (see Vapnik [182]) is to consider the distances $d(u_i, H)$ and $d(v_j, H)$ from *all* the points to the hyperplane H , and to pick a hyperplane H that maximizes the smallest of these distances. In machine learning this strategy is called finding a *maximal margin hyperplane*, or *hard margin support vector machine*, which definitely sounds more impressive.

Since the distance from a point x to the hyperplane H of equation $w^\top x - b = 0$ is

$$d(x, H) = \frac{|w^\top x - b|}{\|w\|},$$

(where $\|w\| = \sqrt{w^\top w}$ is the Euclidean norm of w), it is convenient to temporarily assume that $\|w\| = 1$, so that

$$d(x, H) = |w^\top x - b|.$$

See Figure 50.13. Then with our sign convention, we have

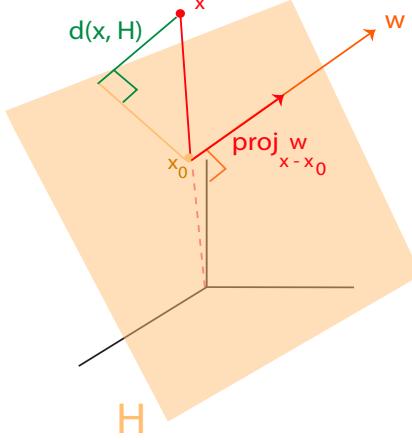

Figure 50.13: In \mathbb{R}^3 , the distance from a point to the plane $w^\top x - b = 0$ is given by the projection onto the normal w .

$$\begin{aligned} d(u_i, H) &= w^\top u_i - b & i = 1, \dots, p \\ d(v_j, H) &= -w^\top v_j + b & j = 1, \dots, q. \end{aligned}$$

If we let

$$\delta = \min\{d(u_i, H), d(v_j, H) \mid 1 \leq i \leq p, 1 \leq j \leq q\},$$

then the hyperplane H should chosen so that

$$\begin{aligned} w^\top u_i - b &\geq \delta & i = 1, \dots, p \\ -w^\top v_j + b &\geq \delta & j = 1, \dots, q, \end{aligned}$$

and such that $\delta > 0$ is *maximal*. The distance δ is called the *margin* associated with the hyperplane H . This is indeed one way of formulating the two-class separation problem as an optimization problem with a linear objective function $J(\delta, w, b) = \delta$, and affine and quadratic constraints (SVM_{h1}):

$$\begin{aligned} &\text{maximize } \delta \\ &\text{subject to} \\ &\quad w^\top u_i - b \geq \delta \quad i = 1, \dots, p \\ &\quad -w^\top v_j + b \geq \delta \quad j = 1, \dots, q \\ &\quad \|w\| \leq 1. \end{aligned}$$

Observe that the Problem (SVM_{h1}) has an optimal solution $\delta > 0$ iff the two subsets are linearly separable. We used the constraint $\|w\| \leq 1$ rather than $\|w\| = 1$ because the former is qualified, whereas the latter is not. But if (w, b, δ) is an optimal solution, then $\|w\| = 1$, as shown in the following proposition.

Proposition 50.12. *If (w, b, δ) is an optimal solution of Problem (SVM_{h1}), so in particular $\delta > 0$, then we must have $\|w\| = 1$.*

Proof. First, if $w = 0$, then we get the two inequalities

$$-b \geq \delta, \quad b \geq \delta,$$

which imply that $b \leq -\delta$ and $b \geq \delta$ for some positive δ , which is impossible. But then, if $w \neq 0$ and $\|w\| < 1$, by dividing both sides of the inequalities by $\|w\| < 1$ we would obtain the better solution $(w/\|w\|, b/\|w\|, \delta/\|w\|)$, since $\|w\| < 1$ implies that $\delta/\|w\| > \delta$. \square

We now prove that if the two subsets are linearly separable, then Problem (SVM_{h1}) has a unique optimal solution.

Theorem 50.13. *If two disjoint subsets of p blue points $\{u_i\}_{i=1}^p$ and q red points $\{v_j\}_{j=1}^q$ are linearly separable, then Problem (SVM_{h1}) has a unique optimal solution consisting of a hyperplane of equation $w^\top x - b = 0$ separating the two subsets with maximum margin δ . Furthermore, if we define $c_1(w)$ and $c_2(w)$ by*

$$\begin{aligned} c_1(w) &= \min_{1 \leq i \leq p} w^\top u_i \\ c_2(w) &= \max_{1 \leq j \leq q} w^\top v_j, \end{aligned}$$

then w is the unique maximum of the function

$$\rho(w) = \frac{c_1(w) - c_2(w)}{2}$$

over the convex subset U of \mathbb{R}^n given by the inequalities

$$\begin{aligned} w^\top u_i - b &\geq \delta & i = 1, \dots, p \\ -w^\top v_j + b &\geq \delta & j = 1, \dots, q \\ \|w\| &\leq 1, \end{aligned}$$

and

$$b = \frac{c_1(w) + c_2(w)}{2}.$$

Proof. Our proof is adapted from Vapnik [182] (Chapter 10, Theorem 10.1). For any separating hyperplane H , since

$$\begin{aligned} d(u_i, H) &= w^\top u_i - b & i = 1, \dots, p \\ d(v_j, H) &= -w^\top v_j + b & j = 1, \dots, q, \end{aligned}$$

and since the smallest distance to H is

$$\begin{aligned} \delta &= \min\{d(u_i, H), d(v_j, H) \mid 1 \leq i \leq p, 1 \leq j \leq q\} \\ &= \min\{w^\top u_i - b, -w^\top v_j + b \mid 1 \leq i \leq p, 1 \leq j \leq q\} \\ &= \min\{\min\{w^\top u_i - b \mid 1 \leq i \leq p\}, \min\{-w^\top v_j + b \mid 1 \leq j \leq q\}\} \\ &= \min\{\min\{w^\top u_i \mid 1 \leq i \leq p\} - b\}, \min\{-w^\top v_j \mid 1 \leq j \leq q\} + b\} \\ &= \min\{\min\{w^\top u_i \mid 1 \leq i \leq p\} - b\}, -\max\{w^\top v_j \mid 1 \leq j \leq q\} + b\} \\ &= \min\{c_1(w) - b, -c_2(w) + b\}, \end{aligned}$$

in order for δ to be maximal we must have

$$c_1(w) - b = -c_2(w) + b,$$

which yields

$$b = \frac{c_1(w) + c_2(w)}{2}.$$

In this case,

$$c_1(w) - b = \frac{c_1(w) - c_2(w)}{2} = -c_2(w) + b,$$

so the maximum margin δ is indeed obtained when $\rho(w) = (c_1(w) - c_2(w))/2$ is maximal over U . Conversely, it is easy to see that any hyperplane of equation $w^\top x - b = 0$ associated with a w maximizing ρ over U and $b = (c_1(w) + c_2(w))/2$ is an optimal solution.

It remains to show that an optimal separating hyperplane exists and is unique. Since the unit ball is compact, U (as defined in Theorem 50.13) is compact, and since the function $w \mapsto \rho(w)$ is continuous, it achieves its maximum for some w_0 such that $\|w_0\| \leq 1$. Actually, we must have $\|w_0\| = 1$, since otherwise, by the reasoning used in Proposition 50.12, $w_0/\|w_0\|$ would be an even better solution. Therefore, w_0 is on the boundary of U . But ρ is a concave function (as an infimum of affine functions), so if it had two distinct maxima w_0 and w'_0 with $\|w_0\| = \|w'_0\| = 1$, these would be global maxima since U is also convex, so we would have $\rho(w_0) = \rho(w'_0)$ and then ρ would also have the same value along the segment (w_0, w'_0) and in particular at $(w_0 + w'_0)/2$, an interior point of U , a contradiction. \square

We can proceed with the above formulation (SVM_{h1}) but there is a way to reformulate the problem so that the constraints are all *affine*, which might be preferable since they will be *automatically qualified*.

50.6 Hard Margin Support Vector Machine; Version II

Since $\delta > 0$ (otherwise the data would not be separable into two disjoint sets), we can divide the affine constraints by δ to obtain

$$\begin{aligned} w'^\top u_i - b' &\geq 1 & i = 1, \dots, p \\ -w'^\top v_j + b' &\geq 1 & j = 1, \dots, q, \end{aligned}$$

except that now, w' is not necessarily a unit vector. To obtain the distances to the hyperplane H , we need to divide by $\|w'\|$ and then we have

$$\begin{aligned} \frac{w'^\top u_i - b'}{\|w'\|} &\geq \frac{1}{\|w'\|} & i = 1, \dots, p \\ \frac{-w'^\top v_j + b'}{\|w'\|} &\geq \frac{1}{\|w'\|} & j = 1, \dots, q, \end{aligned}$$

which means that the shortest distance from the data points to the hyperplane is $1/\|w'\|$. Therefore, we wish to maximize $1/\|w'\|$, that is, to minimize $\|w'\|$, so we obtain the following optimization Problem (SVM _{h_2}):

Hard margin SVM (SVM _{h_2}):

$$\begin{aligned} \text{minimize } & \frac{1}{2} \|w\|^2 \\ \text{subject to } & w^\top u_i - b \geq 1 \quad i = 1, \dots, p \\ & -w^\top v_j + b \geq 1 \quad j = 1, \dots, q. \end{aligned}$$

The objective function $J(w) = 1/2 \|w\|^2$ is convex, so Proposition 50.7 applies and gives us a necessary and sufficient condition for having a minimum in terms of the KKT conditions. First observe that the trivial solution $w = 0$ is impossible, because the blue constraints would be

$$-b \geq 1,$$

that is $b \leq -1$, and the red constraints would be

$$b \geq 1,$$

but these are contradictory. **Our goal is to find w and b , and optionally, δ .** We proceed in four steps first demonstrated on the following example.

Suppose that $p = q = n = 2$, so that we have two blue points

$$u_1^\top = (u_{11}, u_{12}) \quad u_2^\top = (u_{21}, u_{22}),$$

two red points

$$v_1^\top = (v_{11}, v_{12}) \quad v_2^\top = (v_{21}, v_{22}),$$

and

$$w^\top = (w_1, w_2).$$

Step 1: Write the constraints in matrix form. Let

$$C = \begin{pmatrix} -u_{11} & -u_{12} & 1 \\ -u_{21} & -u_{22} & 1 \\ v_{11} & v_{12} & -1 \\ v_{21} & v_{22} & -1 \end{pmatrix} \quad d = \begin{pmatrix} -1 \\ -1 \\ -1 \\ -1 \end{pmatrix}. \quad (M)$$

The constraints become

$$C \begin{pmatrix} w \\ b \end{pmatrix} = \begin{pmatrix} -u_{11} & -u_{12} & 1 \\ -u_{21} & -u_{22} & 1 \\ v_{11} & v_{12} & -1 \\ v_{21} & v_{22} & -1 \end{pmatrix} \begin{pmatrix} w_1 \\ w_2 \\ b \end{pmatrix} \leq \begin{pmatrix} -1 \\ -1 \\ -1 \\ -1 \end{pmatrix}. \quad (C)$$

Step 2: Write the objective function in matrix form.

$$J(w_1, w_2, b) = \frac{1}{2} (w_1 \ w_2 \ b) \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} w_1 \\ w_2 \\ b \end{pmatrix}. \quad (O)$$

Step 3: Apply Proposition 50.7 to solve for w in terms of λ and μ . We obtain

$$\begin{pmatrix} w_1 \\ w_2 \\ 0 \end{pmatrix} + \begin{pmatrix} -u_{11} & -u_{21} & v_{11} & v_{21} \\ -u_{12} & -u_{22} & v_{12} & v_{22} \\ 1 & 1 & -1 & -1 \end{pmatrix} \begin{pmatrix} \lambda_1 \\ \lambda_2 \\ \mu_1 \\ \mu_2 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix},$$

i.e.

$$\nabla J_{(w,b)} + C^\top \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = 0_3, \quad \lambda^\top = (\lambda_1, \lambda_2), \quad \mu^\top = (\mu_1, \mu_2).$$

Then

$$\begin{pmatrix} w_1 \\ w_2 \\ 0 \end{pmatrix} = \begin{pmatrix} u_{11} & u_{21} & -v_{11} & -v_{21} \\ u_{12} & u_{22} & -v_{12} & -v_{22} \\ -1 & -1 & 1 & 1 \end{pmatrix} \begin{pmatrix} \lambda_1 \\ \lambda_2 \\ \mu_1 \\ \mu_2 \end{pmatrix},$$

which implies

$$w = \begin{pmatrix} w_1 \\ w_2 \end{pmatrix} = \lambda_1 \begin{pmatrix} u_{11} \\ u_{12} \end{pmatrix} + \lambda_2 \begin{pmatrix} u_{21} \\ u_{22} \end{pmatrix} - \mu_1 \begin{pmatrix} v_{11} \\ v_{12} \end{pmatrix} - \mu_2 \begin{pmatrix} v_{21} \\ v_{22} \end{pmatrix} \quad (*_1)$$

with respect to

$$\mu_1 + \mu_2 - \lambda_1 - \lambda_2 = 0. \quad (*_2)$$

Step 4: Rewrite the constraints at (C) using $(*_1)$. In particular $C \begin{pmatrix} w \\ b \end{pmatrix} \leq d$ becomes

$$\begin{pmatrix} -u_{11} & -u_{12} & 1 \\ -u_{21} & -u_{22} & 1 \\ v_{11} & v_{12} & -1 \\ v_{21} & v_{22} & -1 \end{pmatrix} \begin{pmatrix} u_{11} & u_{21} & -v_{11} & -v_{21} & 0 \\ u_{12} & u_{22} & -v_{21} & -v_{22} & 0 \\ 0 & 0 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} \lambda_1 \\ \lambda_2 \\ \mu_1 \\ \mu_2 \\ b \end{pmatrix} \leq \begin{pmatrix} -1 \\ -1 \\ -1 \\ -1 \end{pmatrix}.$$

Rewriting the previous equation in “block” format gives us

$$- \begin{pmatrix} -u_{11} & -u_{12} \\ -u_{21} & -u_{22} \\ v_{11} & v_{12} \\ v_{21} & v_{22} \end{pmatrix} \begin{pmatrix} -u_{11} & -u_{21} & v_{11} & v_{21} \\ -u_{12} & -u_{22} & v_{21} & v_{22} \end{pmatrix} \begin{pmatrix} \lambda_1 \\ \lambda_2 \\ \mu_1 \\ \mu_2 \end{pmatrix} + b \begin{pmatrix} 1 \\ 1 \\ -1 \\ 1 \end{pmatrix} + \begin{pmatrix} 1 \\ 1 \\ 1 \\ 1 \end{pmatrix} \leq \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \end{pmatrix},$$

which with the definition

$$X = \begin{pmatrix} -u_{11} & -u_{21} & v_{11} & v_{21} \\ -u_{12} & -u_{22} & v_{21} & v_{22} \end{pmatrix}$$

yields

$$-X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + b \begin{pmatrix} \mathbf{1}_2 \\ -\mathbf{1}_2 \end{pmatrix} + \mathbf{1}_4 \leq 0_4. \quad (*_3)$$

Let us now consider the general case.

Step 1: Write the constraints in matrix form. First we rewrite the constraints as

$$\begin{aligned} -u_i^\top w + b &\leq -1 & i = 1, \dots, p \\ v_j^\top w - b &\leq -1 & j = 1, \dots, q, \end{aligned}$$

and we get the $(p+q) \times (n+1)$ matrix C and the vector $d \in \mathbb{R}^{p+q}$ given by

$$C = \begin{pmatrix} -u_1^\top & 1 \\ \vdots & \vdots \\ -u_p^\top & 1 \\ v_1^\top & -1 \\ \vdots & \vdots \\ v_q^\top & -1 \end{pmatrix}, \quad d = \begin{pmatrix} -1 \\ \vdots \\ -1 \end{pmatrix},$$

so the set of inequality constraints is

$$C \begin{pmatrix} w \\ b \end{pmatrix} \leq d.$$

Step 2: The objective function in matrix form is given by

$$J(w, b) = \frac{1}{2} (w^\top - b) \begin{pmatrix} I_n & 0_n \\ 0_n^\top & 0 \end{pmatrix} \begin{pmatrix} w \\ b \end{pmatrix}.$$

Note that the corresponding matrix is symmetric positive semidefinite, but it is *not* invertible. Thus, the function J is convex but not strictly convex. This will cause some minor trouble in finding the dual function of the problem.

Step 3: If we introduce the generalized Lagrange multipliers $\lambda \in \mathbb{R}^p$ and $\mu \in \mathbb{R}^q$, according to Proposition 50.7, the first KKT condition is

$$\nabla J_{(w,b)} + C^\top \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = 0_{n+1},$$

with $\lambda \geq 0, \mu \geq 0$. By the result of Example 39.5,

$$\nabla J_{(w,b)} = \begin{pmatrix} I_n & 0_n \\ 0_n^\top & 0 \end{pmatrix} \begin{pmatrix} w \\ b \end{pmatrix} = \begin{pmatrix} w \\ 0 \end{pmatrix},$$

so we get

$$\begin{pmatrix} w \\ 0 \end{pmatrix} = -C^\top \begin{pmatrix} \lambda \\ \mu \end{pmatrix},$$

that is,

$$\begin{pmatrix} w \\ 0 \end{pmatrix} = \begin{pmatrix} u_1 & \cdots & u_p & -v_1 & \cdots & -v_q \\ -1 & \cdots & -1 & 1 & \cdots & 1 \end{pmatrix} \begin{pmatrix} \lambda \\ \mu \end{pmatrix}.$$

Consequently,

$$w = \sum_{i=1}^p \lambda_i u_i - \sum_{j=1}^q \mu_j v_j, \quad (*_1)$$

and

$$\sum_{j=1}^q \mu_j - \sum_{i=1}^p \lambda_i = 0. \quad (*_2)$$

Step 4: Rewrite the constraint using $(*_1)$. Plugging the above expression for w into the constraints $C \begin{pmatrix} w \\ b \end{pmatrix} \leq d$ we get

$$\begin{pmatrix} -u_1^\top & 1 \\ \vdots & \vdots \\ -u_p^\top & 1 \\ v_1^\top & -1 \\ \vdots & \vdots \\ v_q^\top & -1 \end{pmatrix} \begin{pmatrix} u_1 & \cdots & u_p & -v_1 & \cdots & -v_q & 0_n \\ 0 & \cdots & 0 & 0 & \cdots & 0 & 1 \end{pmatrix} \begin{pmatrix} \lambda \\ \mu \\ b \end{pmatrix} \leq \begin{pmatrix} -1 \\ \vdots \\ -1 \end{pmatrix},$$

so if let X be the $n \times (p + q)$ matrix given by

$$X = \begin{pmatrix} -u_1 & \cdots & -u_p & v_1 & \cdots & v_q \end{pmatrix},$$

we obtain

$$w = -X \begin{pmatrix} \lambda \\ \mu \end{pmatrix}, \quad (*'_1)$$

and the above inequalities are written in matrix form as

$$\begin{pmatrix} X^\top & \mathbf{1}_p \\ -\mathbf{1}_q \end{pmatrix} \begin{pmatrix} -X & 0_n \\ 0_{p+q}^\top & 1 \end{pmatrix} \begin{pmatrix} \lambda \\ \mu \\ b \end{pmatrix} \leq -\mathbf{1}_{p+q};$$

that is,

$$-X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + b \begin{pmatrix} \mathbf{1}_p \\ -\mathbf{1}_q \end{pmatrix} + \mathbf{1}_{p+q} \leq 0_{p+q}. \quad (*_3)$$

Equivalently, the i th inequality is

$$-\sum_{j=1}^p u_i^\top u_j \lambda_j + \sum_{k=1}^q u_i^\top v_k \mu_k + b + 1 \leq 0 \quad i = 1, \dots, p,$$

and the $(p+j)$ th inequality is

$$\sum_{i=1}^p v_j^\top u_i \lambda_i - \sum_{k=1}^q v_j^\top v_k \mu_k - b + 1 \leq 0 \quad j = 1, \dots, q.$$

We also have $\lambda \geq 0, \mu \geq 0$. Furthermore, if the i th inequality is inactive, then $\lambda_i = 0$, and if the $(p+j)$ th inequality is inactive, then $\mu_j = 0$. Since the constraints are affine and since J is convex, if we can find $\lambda \geq 0, \mu \geq 0$, and b such that the inequalities in $(*_3)$ are satisfied, and $\lambda_i = 0$ and $\mu_j = 0$ when the corresponding constraint is inactive, then by Proposition 50.7 we have an optimum solution.

Remark: The second KKT condition can be written as

$$(\lambda^\top \ \mu^\top) \left(-X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + b \begin{pmatrix} \mathbf{1}_p \\ -\mathbf{1}_q \end{pmatrix} + \mathbf{1}_{p+q} \right) = 0;$$

that is,

$$-(\lambda^\top \ \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + b (\lambda^\top \ \mu^\top) \begin{pmatrix} \mathbf{1}_p \\ -\mathbf{1}_q \end{pmatrix} + (\lambda^\top \ \mu^\top) \mathbf{1}_{p+q} = 0.$$

Since $(*_2)$ says that $\sum_{i=1}^p \lambda_i = \sum_{j=1}^q \mu_j$, the second term is zero, and by $(*_1')$ we get

$$w^\top w = (\lambda^\top \ \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = \sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j.$$

Thus, we obtain a simple expression for $\|w\|^2$ in terms of λ and μ .

The vectors u_i and v_j for which the i -th inequality is active and the $(p+j)$ th inequality is active are called *support vectors*. For every vector u_i or v_j that is not a support vector, the corresponding inequality is inactive, so $\lambda_i = 0$ and $\mu_j = 0$. Thus we see that *only the support vectors contribute to a solution*. If we can *guess* which vectors u_i and v_j are support vectors, namely, those for which $\lambda_i \neq 0$ and $\mu_j \neq 0$, then for each support vector u_i we have an equation

$$-\sum_{j=1}^p u_i^\top u_j \lambda_j + \sum_{k=1}^q u_i^\top v_k \mu_k + b + 1 = 0,$$

and for each support vector v_j we have an equation

$$\sum_{i=1}^p v_j^\top u_i \lambda_i - \sum_{k=1}^q v_j^\top v_k \mu_k - b + 1 = 0,$$

with $\lambda_i = 0$ and $\mu_j = 0$ for all non-support vectors, so together with the Equation $(*_2)$ we have a linear system with an equal number of equations and variables, which is solvable if our separation problem has a solution. Thus, in principle we can find λ , μ , and b by solving a linear system.

Remark: We can first solve for λ and μ (by eliminating b), and by $(*_1)$ and since $w \neq 0$, there is at least some nonzero λ_{i_0} and thus some nonzero μ_{j_0} , so the corresponding inequalities are equations

$$\begin{aligned} & -\sum_{j=1}^p u_{i_0}^\top u_j \lambda_j + \sum_{k=1}^q u_{i_0}^\top v_k \mu_k + b + 1 = 0 \\ & \sum_{i=1}^p v_{j_0}^\top u_i \lambda_i - \sum_{k=1}^q v_{j_0}^\top v_k \mu_k - b + 1 = 0, \end{aligned}$$

so b is given in terms of λ and μ by

$$b = \frac{1}{2}(u_{i_0}^\top + v_{j_0}^\top) \left(\sum_{i=1}^p \lambda_i u_i - \sum_{j=1}^p \mu_j v_j \right).$$

Using the dual of the Lagrangian, we can solve for λ and μ , but typically b is not determined, so we use the above method to find b .

The above nondeterministic procedure in which we guess which vectors are support vectors is not practical. We will see later that a practical method for solving for λ and μ consists in maximizing the dual of the Lagrangian.

If w is an optimal solution, then $\delta = 1/\|w\|$ is the shortest distance from the support vectors to the separating hyperplane $H_{w,b}$ of equation $w^\top x - b = 0$. If we consider the two hyperplanes $H_{w,b+1}$ and $H_{w,b-1}$ of equations

$$w^\top x - b - 1 = 0 \quad \text{and} \quad w^\top x - b + 1 = 0,$$

then $H_{w,b+1}$ and $H_{w,b-1}$ are two hyperplanes parallel to the hyperplane $H_{w,b}$ and the distance between them is 2δ . Furthermore, $H_{w,b+1}$ contains the support vectors u_i , $H_{w,b-1}$ contains the support vectors v_j , and there are no data points u_i or v_j in the open region between these two hyperplanes containing the separating hyperplane $H_{w,b}$ (called a “slab” by Boyd and Vandenberghe; see [29], Section 8.6). This situation is illustrated in Figure 50.14.

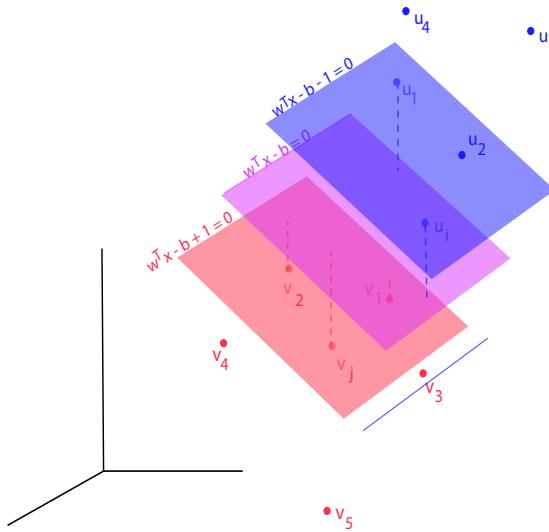

Figure 50.14: In \mathbb{R}^3 , the solution to Hard Margin SVM_{h2} is the purple plane sandwiched between the red plane $w^\top x - b + 1 = 0$ and the blue plane $w^\top x - b - 1 = 0$, each of which contains the appropriate support vectors u_i and v_j .

Even if $p = 1$ and $q = 2$, a solution is not obvious. In the plane, there are four possibilities:

- (1) If u_1 is on the segment (v_1, v_2) , there is no solution.
- (2) If the projection h of u_1 onto the line determined by v_1 and v_2 is between v_1 and v_2 , that is $h = (1 - \alpha)v_1 + \alpha_2v_2$ with $0 \leq \alpha \leq 1$, then it is the line parallel to $v_2 - v_1$ and equidistant to u and both v_1 and v_2 , as illustrated in Figure 50.15.
- (3) If the projection h of u_1 onto the line determined by v_1 and v_2 is to the right of v_2 , that is $h = (1 - \alpha)v_1 + \alpha_2v_2$ with $\alpha > 1$, then it is the bisector of the line segment (u_1, v_2) .
- (4) If the projection h of u_1 onto the line determined by v_1 and v_2 is to the left of v_1 , that is $h = (1 - \alpha)v_1 + \alpha_2v_2$ with $\alpha < 0$, then it is the bisector of the line segment (u_1, v_1) .

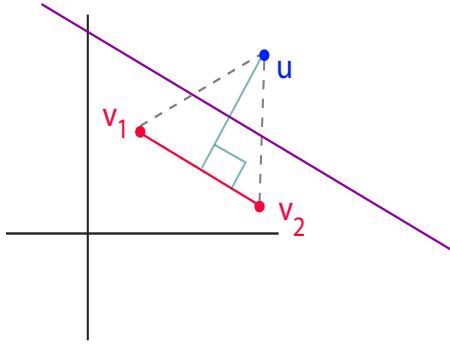

Figure 50.15: The purple line, which is the bisector of the altitude of the isosceles triangle, separates the two red points from the blue point in a manner which satisfies Hard Margin SVM _{$h2$} .

If $p = q = 1$, we can find a solution explicitly. Then $(*_2)$ yields

$$\lambda = \mu,$$

and if we guess that the constraints are active, the corresponding equality constraints are

$$\begin{aligned} -u^\top u\lambda + u^\top v\mu + b + 1 &= 0 \\ u^\top v\lambda - v^\top v\mu - b + 1 &= 0, \end{aligned}$$

so we get

$$\begin{aligned} (-u^\top u + u^\top v)\lambda + b + 1 &= 0 \\ (u^\top v - v^\top v)\lambda - b + 1 &= 0, \end{aligned}$$

Adding up the two equations we find

$$(2u^\top v - u^\top u - v^\top v)\lambda + 2 = 0,$$

that is

$$\lambda = \frac{2}{(u - v)^\top(u - v)}.$$

By subtracting the first equation from the second, we find

$$(u^\top u - v^\top v)\lambda - 2b = 0,$$

which yields

$$b = \lambda \frac{(u^\top u - v^\top v)}{2} = \frac{u^\top u - v^\top v}{(u - v)^\top(u - v)}.$$

Then by $(*_1)$ we obtain

$$w = \frac{2(u - v)}{(u - v)^\top(u - v)}.$$

We verify easily that

$$2(u_1 - v_1)x_1 + \cdots + 2(u_n - v_n)x_n = (u_1^2 + \cdots + u_n^2) - (v_1^2 + \cdots + v_n^2)$$

is the equation of the bisector hyperplane between u and v ; see Figure 50.16.

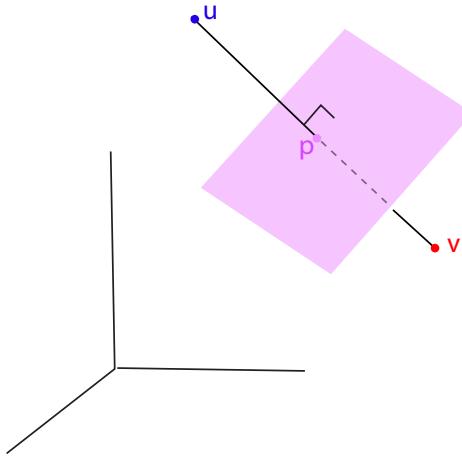

Figure 50.16: In \mathbb{R}^3 , the solution to Hard Margin SVM _{h_2} for the points u and v is the purple perpendicular planar bisector of $u - v$.

In the next section we will derive the dual of the optimization problem discussed in this section. We will also consider a more flexible solution involving a *soft margin*.

50.7 Lagrangian Duality and Saddle Points

In this section we investigate methods to solve the *Minimization Problem (P)*:

$$\begin{aligned} & \text{minimize} && J(v) \\ & \text{subject to} && \varphi_i(v) \leq 0, \quad i = 1, \dots, m. \end{aligned}$$

It turns out that under certain conditions the original Problem (P), called *primal problem*, can be solved in two stages with the help another Problem (D), called the *dual problem*. The Dual Problem (D) is a *maximization problem* involving a function G , called the *Lagrangian*

dual, and it is obtained by *minimizing* the *Lagrangian* $L(v, \mu)$ of Problem (P) over the variable $v \in \mathbb{R}^n$, holding μ fixed, where $L: \Omega \times \mathbb{R}_+^m \rightarrow \mathbb{R}$ is given by

$$L(v, \mu) = J(v) + \sum_{i=1}^m \mu_i \varphi_i(v),$$

with $\mu \in \mathbb{R}_+^m$.

The two steps of the method are:

- (1) Find the dual function $\mu \mapsto G(\mu)$ explicitly by solving the minimization problem of finding the minimum of $L(v, \mu)$ with respect to $v \in \Omega$, holding μ fixed. This is an unconstrained minimization problem (with $v \in \Omega$). If we are lucky, a unique minimizer u_μ such that $G(\mu) = L(u_\mu, \mu)$ can be found. We will address the issue of uniqueness later on.
- (2) Solve the maximization problem of finding the maximum of the function $\mu \mapsto G(\mu)$ over all $\mu \in \mathbb{R}_+^m$. This is basically an unconstrained problem, except for the fact that $\mu \in \mathbb{R}_+^m$.

If Steps (1) and (2) are successful, under some suitable conditions on the function J and the constraints φ_i (for example, if they are convex), for any solution $\lambda \in \mathbb{R}_+^m$ obtained in Step (2), the vector u_λ obtained in Step (1) is an optimal solution of Problem (P) . This is proven in Theorem 50.17.

In order to prove Theorem 50.17, which is our main result, we need two intermediate technical results of independent interest involving the notion of saddle point.

The local minima of a function $J: \Omega \rightarrow \mathbb{R}$ over a domain U defined by inequality constraints are saddle points of the Lagrangian $L(v, \mu)$ associated with J and the constraints φ_i . Then, under some mild hypotheses, the set of solutions of the *Minimization Problem* (P)

$$\begin{aligned} & \text{minimize } J(v) \\ & \text{subject to } \varphi_i(v) \leq 0, \quad i = 1, \dots, m \end{aligned}$$

coincides with the set of first arguments of the saddle points of the Lagrangian

$$L(v, \mu) = J(v) + \sum_{i=1}^m \mu_i \varphi_i(v).$$

This is proved in Theorem 50.15. To prove Theorem 50.17, we also need Proposition 50.14, a basic property of saddle points.

Definition 50.7. Let $L: \Omega \times M \rightarrow \mathbb{R}$ be a function defined on a set of the form $\Omega \times M$, where Ω and M are open subsets of two normed vector spaces. A point $(u, \lambda) \in \Omega \times M$ is a *saddle point* of L if u is a minimum of the function $L(-, \lambda): \Omega \rightarrow \mathbb{R}$ given by $v \mapsto L(v, \lambda)$ for all $v \in \Omega$ and λ fixed, and λ is a maximum of the function $L(u, -): M \rightarrow \mathbb{R}$ given by $\mu \mapsto L(u, \mu)$ for all $\mu \in M$ and u fixed; equivalently,

$$\sup_{\mu \in M} L(u, \mu) = L(u, \lambda) = \inf_{v \in \Omega} L(v, \lambda).$$

Note that the order of the arguments u and λ is important. The second set M will be the set of generalized multipliers, and this is why we use the symbol M . Typically, $M = \mathbb{R}_+^m$.

A saddle point is often depicted as a mountain pass, which explains the terminology; see Figure 50.17. However, this is a bit misleading since other situations are possible; see Figure 50.18.

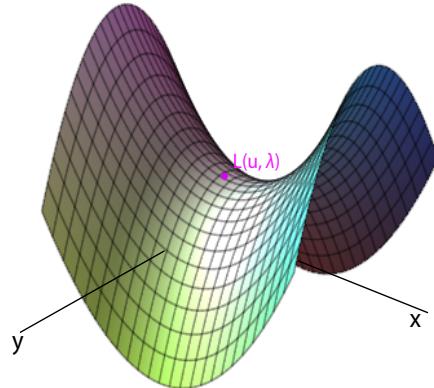

Figure 50.17: A three-dimensional rendition of a saddle point $L(u, \lambda)$ for the function $L(u, \lambda) = u^2 - \lambda^2$. The plane $x = u$ provides a maximum as the apex of a downward opening parabola, while the plane $y = \lambda$ provides a minimum as the apex of an upward opening parabola.

Proposition 50.14. If (u, λ) is a saddle point of a function $L: \Omega \times M \rightarrow \mathbb{R}$, then

$$\sup_{\mu \in M} \inf_{v \in \Omega} L(v, \mu) = L(u, \lambda) = \inf_{v \in \Omega} \sup_{\mu \in M} L(v, \mu).$$

Proof. First we prove that the following inequality always holds:

$$\sup_{\mu \in M} \inf_{v \in \Omega} L(v, \mu) \leq \inf_{v \in \Omega} \sup_{\mu \in M} L(v, \mu). \quad (*_1)$$

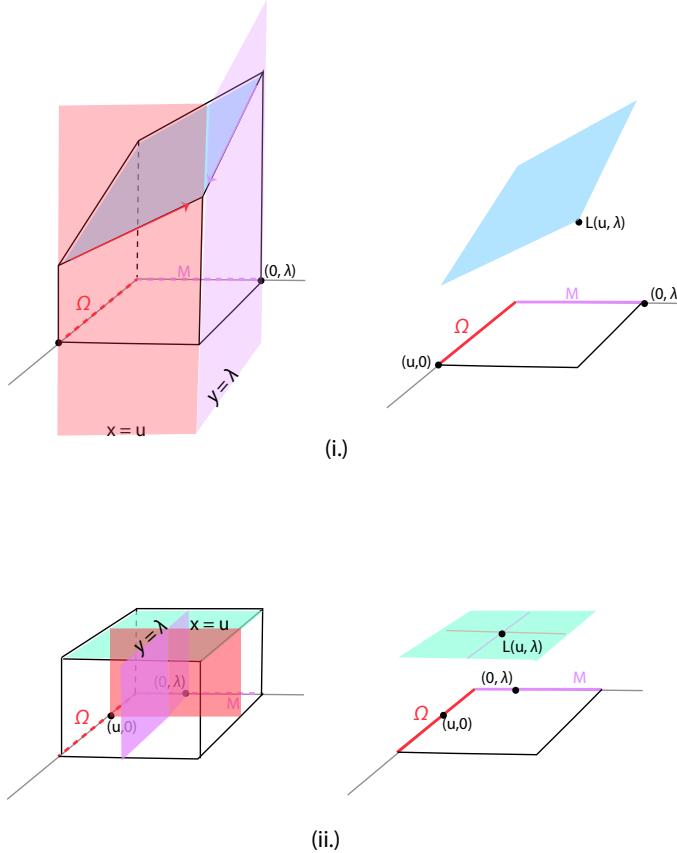

Figure 50.18: Let $\Omega = \{[t, 0, 0] \mid 0 \leq t \leq 1\}$ and $M = \{[0, t, 0] \mid 0 \leq t \leq 1\}$. In Figure (i.), $L(u, \lambda)$ is the blue slanted quadrilateral whose forward vertex is a saddle point. In Figure (ii.), $L(u, \lambda)$ is the planar green rectangle composed entirely of saddle points.

Pick any $w \in \Omega$ and any $\rho \in M$. By definition of \inf (the greatest lower bound) and \sup (the least upper bound), we have

$$\inf_{v \in \Omega} L(v, \rho) \leq L(w, \rho) \leq \sup_{\mu \in M} L(w, \mu).$$

The cases where $\inf_{v \in \Omega} L(v, \rho) = -\infty$ or where $\sup_{\mu \in M} L(w, \mu) = +\infty$ may arise, but this is not a problem. Since

$$\inf_{v \in \Omega} L(v, \rho) \leq \sup_{\mu \in M} L(w, \mu)$$

and the right-hand side is independent of ρ , it is an upper bound of the left-hand side for all ρ , so

$$\sup_{\mu \in M} \inf_{v \in \Omega} L(v, \mu) \leq \sup_{\mu \in M} L(w, \mu).$$

Since the left-hand side is independent of w , it is a lower bound for the right-hand side for all w , so we obtain $(*_1)$:

$$\sup_{\mu \in M} \inf_{v \in \Omega} L(v, \mu) \leq \inf_{v \in \Omega} \sup_{\mu \in M} L(v, \mu).$$

To obtain the reverse inequality, we use the fact that (u, λ) is a saddle point, so

$$\inf_{v \in \Omega} \sup_{\mu \in M} L(v, \mu) \leq \sup_{\mu \in M} L(u, \mu) = L(u, \lambda)$$

and

$$L(u, \lambda) = \inf_{v \in \Omega} L(v, \lambda) \leq \sup_{\mu \in M} \inf_{v \in \Omega} L(v, \mu),$$

and these imply that

$$\inf_{v \in \Omega} \sup_{\mu \in M} L(v, \mu) \leq \sup_{\mu \in M} \inf_{v \in \Omega} L(v, \mu), \quad (*_2)$$

as desired. \square

We now return to our main Minimization Problem (P) :

$$\begin{aligned} & \text{minimize} && J(v) \\ & \text{subject to} && \varphi_i(v) \leq 0, \quad i = 1, \dots, m, \end{aligned}$$

where $J: \Omega \rightarrow \mathbb{R}$ and the constraints $\varphi_i: \Omega \rightarrow \mathbb{R}$ are some functions defined on some open subset Ω of some finite-dimensional Euclidean vector space V (more generally, a real Hilbert space V).

Definition 50.8. The *Lagrangian* of the Minimization Problem (P) defined above is the function $L: \Omega \times \mathbb{R}_+^m \rightarrow \mathbb{R}$ given by

$$L(v, \mu) = J(v) + \sum_{i=1}^m \mu_i \varphi_i(v),$$

with $\mu = (\mu_1, \dots, \mu_m)$. The numbers μ_i are called *generalized Lagrange multipliers*.

The following theorem shows that under some suitable conditions, every solution u of the Problem (P) is the first argument of a saddle point (u, λ) of the Lagrangian L , and conversely, if (u, λ) is a saddle point of the Lagrangian L , then u is a solution of the Problem (P) .

Theorem 50.15. Consider Problem (P) defined above where $J: \Omega \rightarrow \mathbb{R}$ and the constraints $\varphi_i: \Omega \rightarrow \mathbb{R}$ are some functions defined on some open subset Ω of some finite-dimensional Euclidean vector space V (more generally, a real Hilbert space V). The following facts hold.

- (1) If $(u, \lambda) \in \Omega \times \mathbb{R}_+^m$ is a saddle point of the Lagrangian L associated with Problem (P) , then $u \in U$, u is a solution of Problem (P) , and $J(u) = L(u, \lambda)$.

- (2) If Ω is convex (open), if the functions φ_i ($1 \leq i \leq m$) and J are convex and differentiable at the point $u \in U$, if the constraints are qualified, and if $u \in U$ is a minimum of Problem (P) , then there exists some vector $\lambda \in \mathbb{R}_+^m$ such that the pair $(u, \lambda) \in \Omega \times \mathbb{R}_+^m$ is a saddle point of the Lagrangian L .

Proof. (1) Since (u, λ) is a saddle point of L we have $\sup_{\mu \in \mathbb{R}_+^m} L(u, \mu) = L(u, \lambda)$ which implies that $L(u, \mu) \leq L(u, \lambda)$ for all $\mu \in \mathbb{R}_+^m$, which means that

$$J(u) + \sum_{i=1}^m \mu_i \varphi_i(u) \leq J(u) + \sum_{i=1}^m \lambda_i \varphi_i(u),$$

that is,

$$\sum_{i=1}^m (\mu_i - \lambda_i) \varphi_i(u) \leq 0 \quad \text{for all } \mu \in \mathbb{R}_+^m.$$

If we let each μ_i be large enough, then $\mu_i - \lambda_i > 0$, and if we had $\varphi_i(u) > 0$, then the term $(\mu_i - \lambda_i)\varphi_i(u)$ could be made arbitrarily large and positive, so we conclude that $\varphi_i(u) \leq 0$ for $i = 1, \dots, m$, and consequently, $u \in U$. For $\mu = 0$, we conclude that $\sum_{i=1}^m \lambda_i \varphi_i(u) \geq 0$. However, since $\lambda_i \geq 0$ and $\varphi_i(u) \leq 0$, (since $u \in U$), we have $\sum_{i=1}^m \lambda_i \varphi_i(u) \leq 0$. Combining these two inequalities shows that

$$\sum_{i=1}^m \lambda_i \varphi_i(u) = 0. \tag{*_1}$$

This shows that $J(u) = L(u, \lambda)$. Since the inequality $L(u, \lambda) \leq L(v, \lambda)$ is

$$J(u) + \sum_{i=1}^m \lambda_i \varphi_i(u) \leq J(v) + \sum_{i=1}^m \lambda_i \varphi_i(v),$$

by $(*_1)$ we obtain

$$\begin{aligned} J(u) &\leq J(v) + \sum_{i=1}^m \lambda_i \varphi_i(v) && \text{for all } v \in \Omega \\ &\leq J(v) && \text{for all } v \in U \text{ (since } \varphi_i(v) \leq 0 \text{ and } \lambda_i \geq 0\text{),} \end{aligned}$$

which shows that u is a minimum of J on U .

(2) The hypotheses required to apply Theorem 50.6(1) are satisfied. Consequently if $u \in U$ is a solution of Problem (P) , then there exists some vector $\lambda \in \mathbb{R}_+^m$ such that the KKT conditions hold:

$$J'(u) + \sum_{i=1}^m \lambda_i (\varphi'_i)_u = 0 \quad \text{and} \quad \sum_{i=1}^m \lambda_i \varphi_i(u) = 0.$$

The second equation yields

$$L(u, \mu) = J(u) + \sum_{i=1}^m \mu_i \varphi_i(u) \leq J(u) = J(u) + \sum_{i=1}^m \lambda_i \varphi_i(u) = L(u, \lambda),$$

that is,

$$L(u, \mu) \leq L(u, \lambda) \quad \text{for all } \mu \in \mathbb{R}_+^m \quad (*_2)$$

(since $\varphi_i(u) \leq 0$ as $u \in U$), and since the function $v \mapsto J(v) + \sum_{i=1}^m \lambda_i \varphi_i(v) = L(v, \lambda)$ is convex as a sum of convex functions, by Theorem 40.13(4), the first equation is a sufficient condition for the existence of minimum. Consequently,

$$L(u, \lambda) \leq L(v, \lambda) \quad \text{for all } v \in \Omega, \quad (*_3)$$

and $(*_2)$ and $(*_3)$ show that (u, λ) is a saddle point of L . \square

To recap what we just proved, under some mild hypotheses, the set of solutions of the Minimization Problem (P)

$$\begin{aligned} & \text{minimize} && J(v) \\ & \text{subject to} && \varphi_i(v) \leq 0, \quad i = 1, \dots, m \end{aligned}$$

coincides with the set of first arguments of the saddle points of the Lagrangian

$$L(v, \mu) = J(v) + \sum_{i=1}^m \mu_i \varphi_i(v),$$

and for any optimum $u \in U$ of Problem (P) , we have $J(u) = L(u, \lambda)$.

Therefore, if we knew some particular second argument λ of these saddle points, then the *constrained* Problem (P) would be replaced by the *unconstrained* Problem (P_λ) :

$$\begin{aligned} & \text{find } u_\lambda \in \Omega \text{ such that} \\ & L(u_\lambda, \lambda) = \inf_{v \in \Omega} L(v, \lambda). \end{aligned}$$

How do we find such an element $\lambda \in \mathbb{R}_+^m$?

For this, remember that for a saddle point (u_λ, λ) , by Proposition 50.14, we have

$$L(u_\lambda, \lambda) = \inf_{v \in \Omega} L(v, \lambda) = \sup_{\mu \in \mathbb{R}_+^m} \inf_{v \in \Omega} L(v, \mu),$$

so we are naturally led to introduce the function $G: \mathbb{R}_+^m \rightarrow \mathbb{R}$ given by

$$G(\mu) = \inf_{v \in \Omega} L(v, \mu) \quad \mu \in \mathbb{R}_+^m,$$

and then λ will be a solution of the problem

$$\begin{aligned} & \text{find } \lambda \in \mathbb{R}_+^m \text{ such that} \\ & G(\lambda) = \sup_{\mu \in \mathbb{R}_+^m} G(\mu), \end{aligned}$$

which is equivalent to the *Maximization Problem (D)*:

$$\begin{aligned} & \text{maximize } G(\mu) \\ & \text{subject to } \mu \in \mathbb{R}_+^m. \end{aligned}$$

Definition 50.9. Given the Minimization Problem (*P*)

$$\begin{aligned} & \text{minimize } J(v) \\ & \text{subject to } \varphi_i(v) \leq 0, \quad i = 1, \dots, m, \end{aligned}$$

where $J: \Omega \rightarrow \mathbb{R}$ and the constraints $\varphi_i: \Omega \rightarrow \mathbb{R}$ are some functions defined on some open subset Ω of some finite-dimensional Euclidean vector space V (more generally, a real Hilbert space V), the function $G: \mathbb{R}_+^m \rightarrow \mathbb{R}$ given by

$$G(\mu) = \inf_{v \in \Omega} L(v, \mu) \quad \mu \in \mathbb{R}_+^m,$$

is called the *Lagrange dual function* (or simply *dual function*). The *Problem (D)*

$$\begin{aligned} & \text{maximize } G(\mu) \\ & \text{subject to } \mu \in \mathbb{R}_+^m \end{aligned}$$

is called the *Lagrange dual problem*. The Problem (*P*) is often called the *primal problem*, and (*D*) is the *dual problem*. The variable μ is called the *dual variable*. The variable $\mu \in \mathbb{R}_+^m$ is said to be *dual feasible* if $G(\mu)$ is defined (not $-\infty$). If $\lambda \in \mathbb{R}_+^m$ is a maximum of G , then we call it a *dual optimal* or an *optimal Lagrange multiplier*.

Since

$$L(v, \mu) = J(v) + \sum_{i=1}^m \mu_i \varphi_i(v),$$

the function $G(\mu) = \inf_{v \in \Omega} L(v, \mu)$ is the pointwise infimum of some affine functions of μ , so it is *concave*, even if the φ_i are not convex. One of the main advantages of the dual problem over the primal problem is that it is a *convex optimization problem*, since we wish to maximize a concave objective function G (thus minimize $-G$, a convex function), and the constraints $\mu \geq 0$ are convex. In a number of practical situations, the dual function G can indeed be computed.

To be perfectly rigorous, we should mention that the dual function G is actually a *partial function*, because it takes the value $-\infty$ when the map $v \mapsto L(v, \mu)$ is unbounded below.

Example 50.5. Consider the Linear Program (P)

$$\begin{aligned} & \text{minimize} && c^\top v \\ & \text{subject to} && Av \leq b, \quad v \geq 0, \end{aligned}$$

where A is an $m \times n$ matrix. The constraints $v \geq 0$ are rewritten as $-v_i \leq 0$, so we introduce Lagrange multipliers $\mu \in \mathbb{R}_+^m$ and $\nu \in \mathbb{R}_+^n$, and we have the Lagrangian

$$\begin{aligned} L(v, \mu, \nu) &= c^\top v + \mu^\top (Av - b) - \nu^\top v \\ &= -b^\top \mu + (c + A^\top \mu - \nu)^\top v. \end{aligned}$$

The linear function $v \mapsto (c + A^\top \mu - \nu)^\top v$ is unbounded below unless $c + A^\top \mu - \nu = 0$, so the dual function $G(\mu, \nu) = \inf_{v \in \mathbb{R}^n} L(v, \mu, \nu)$ is given for all $\mu \geq 0$ and $\nu \geq 0$ by

$$G(\mu, \nu) = \begin{cases} -b^\top \mu & \text{if } A^\top \mu - \nu + c = 0, \\ -\infty & \text{otherwise.} \end{cases}$$

The domain of G is a proper subset of $\mathbb{R}_+^m \times \mathbb{R}_+^n$.

Observe that the value $G(\mu, \nu)$ of the function G , when it is defined, is independent of the second argument ν . Since we are interested in maximizing G , this suggests introducing the function \widehat{G} of the single argument μ given by

$$\widehat{G}(\mu) = -b^\top \mu,$$

which is defined for all $\mu \in \mathbb{R}_+^m$.

Of course, $\sup_{\mu \in \mathbb{R}_+^m} \widehat{G}(\mu)$ and $\sup_{(\mu, \nu) \in \mathbb{R}_+^m \times \mathbb{R}_+^n} G(\mu, \nu)$ are generally different, but note that $\widehat{G}(\mu) = G(\mu, \nu)$ iff there is some $\nu \in \mathbb{R}_+^n$ such that $A^\top \mu - \nu + c = 0$ iff $A^\top \mu + c \geq 0$. Therefore, finding $\sup_{(\mu, \nu) \in \mathbb{R}_+^m \times \mathbb{R}_+^n} G(\mu, \nu)$ is equivalent to the constrained Problem (D_1)

$$\begin{aligned} & \text{maximize} && -b^\top \mu \\ & \text{subject to} && A^\top \mu \geq -c, \quad \mu \geq 0. \end{aligned}$$

The above problem is the dual of the Linear Program (P) .

In summary, the dual function G of a primary Problem (P) often contains hidden inequality constraints that define its domain, and sometimes it is possible to make these domain constraints $\psi_1(\mu) \leq 0, \dots, \psi_p(\mu) \leq 0$ explicit, to define a new function \widehat{G} that depends only on $q < m$ of the variables μ_i and is defined for all values $\mu_i \geq 0$ of these variables, and to replace the Maximization Problem (D) , find $\sup_{\mu \in \mathbb{R}_+^m} G(\mu)$, by the constrained Problem (D_1)

$$\begin{aligned} & \text{maximize} && \widehat{G}(\mu) \\ & \text{subject to} && \psi_i(\mu) \leq 0, \quad i = 1, \dots, p. \end{aligned}$$

Problem (D_1) is different from the Dual Program (D) , but it is equivalent to (D) as a maximization problem.

50.8 Weak and Strong Duality

Another important property of the dual function G is that it provides a *lower bound* on the value of the objective function J . Indeed, we have

$$G(\mu) \leq L(u, \mu) \leq J(u) \quad \text{for all } u \in U \text{ and all } \mu \in \mathbb{R}_+^m, \quad (\dagger)$$

since $\mu \geq 0$ and $\varphi_i(u) \leq 0$ for $i = 1, \dots, m$, so

$$G(\mu) = \inf_{v \in \Omega} L(v, \mu) \leq L(u, \mu) = J(u) + \sum_{i=1}^m \mu_i \varphi_i(u) \leq J(u).$$

If the Primal Problem (P) has a minimum denoted p^* and the Dual Problem (D) has a maximum denoted d^* , then the above inequality implies that

$$d^* \leq p^* \quad (\dagger_w)$$

known as *weak duality*. Equivalently, for every optimal solution λ^* of the dual problem and every optimal solution u^* of the primal problem, we have

$$G(\lambda^*) \leq J(u^*). \quad (\dagger_{w'})$$

In particular, if $p^* = -\infty$, which means that the primal problem is unbounded below, then the dual problem is unfeasible. Conversely, if $d^* = +\infty$, which means that the dual problem is unbounded above, then the primal problem is unfeasible.

Definition 50.10. The difference $p^* - d^* \geq 0$ is called the *optimal duality gap*. If the duality gap is zero, that is, $p^* = d^*$, then we say that *strong duality* holds.

Even when the duality gap is strictly positive, the inequality (\dagger_w) can be helpful to find a lower bound on the optimal value of a primal problem that is difficult to solve, since the dual problem is *always* convex.

If the primal problem and the dual problem are feasible and if the optimal values p^* and d^* are finite and $p^* = d^*$ (no duality gap), then the complementary slackness conditions hold for the inequality constraints.

Proposition 50.16. (*Complementary Slackness*) Given the Minimization Problem (P)

$$\begin{aligned} & \text{minimize} && J(v) \\ & \text{subject to} && \varphi_i(v) \leq 0, \quad i = 1, \dots, m, \end{aligned}$$

and its Dual Problem (D)

$$\begin{aligned} & \text{maximize} && G(\mu) \\ & \text{subject to} && \mu \in \mathbb{R}_+^m, \end{aligned}$$

if both (P) and (D) are feasible, $u \in U$ is an optimal solution of (P) , $\lambda \in \mathbb{R}_+^m$ is an optimal solution of (D) , and $J(u) = G(\lambda)$, then

$$\sum_{i=1}^m \lambda_i \varphi_i(u) = 0.$$

In other words, if the constraint φ_i is inactive at u , then $\lambda_i = 0$.

Proof. Since $J(u) = G(\lambda)$ we have

$$\begin{aligned} J(u) &= G(\lambda) \\ &= \inf_{v \in \Omega} \left(J(v) + \sum_{i=1}^m \lambda_i \varphi_i(v) \right) && \text{by definition of } G \\ &\leq J(u) + \sum_{i=1}^m \lambda_i \varphi_i(u) && \text{the greatest lower bound is a lower bound} \\ &\leq J(u) && \text{since } \lambda_i \geq 0, \varphi_i(u) \leq 0. \end{aligned}$$

which implies that $\sum_{i=1}^m \lambda_i \varphi_i(u) = 0$. \square

Going back to Example 50.5, we see that weak duality says that for any feasible solution u of the Primal Problem (P) , that is, some $u \in \mathbb{R}^n$ such that

$$Au \leq b, \quad u \geq 0,$$

and for any feasible solution $\mu \in \mathbb{R}^m$ of the Dual Problem (D_1) , that is,

$$A^\top \mu \geq -c, \quad \mu \geq 0,$$

we have

$$-b^\top \mu \leq c^\top u.$$

Actually, if u and λ are optimal, then we know from Theorem 47.7 that strong duality holds, namely $-b^\top \mu = c^\top u$, but the proof of this fact is nontrivial.

The following theorem establishes a link between the solutions of the Primal Problem (P) and those of the Dual Problem (D) . It also gives sufficient conditions for the duality gap to be zero.

Theorem 50.17. Consider the Minimization Problem (P) :

$$\begin{aligned} &\text{minimize} && J(v) \\ &\text{subject to} && \varphi_i(v) \leq 0, \quad i = 1, \dots, m, \end{aligned}$$

where the functions J and φ_i are defined on some open subset Ω of a finite-dimensional Euclidean vector space V (more generally, a real Hilbert space V).

- (1) Suppose the functions $\varphi_i: \Omega \rightarrow \mathbb{R}$ are continuous, and that for every $\mu \in \mathbb{R}_+^m$, the Problem (P_μ) :

$$\begin{aligned} & \text{minimize} && L(v, \mu) \\ & \text{subject to} && v \in \Omega, \end{aligned}$$

has a unique solution u_μ , so that

$$L(u_\mu, \mu) = \inf_{v \in \Omega} L(v, \mu) = G(\mu),$$

and the function $\mu \mapsto u_\mu$ is continuous (on \mathbb{R}_+^m). Then the function G is differentiable for all $\mu \in \mathbb{R}_+^m$, and

$$G'_\mu(\xi) = \sum_{i=1}^m \xi_i \varphi_i(u_\mu) \quad \text{for all } \xi \in \mathbb{R}^m.$$

If λ is any solution of Problem (D) :

$$\begin{aligned} & \text{maximize} && G(\mu) \\ & \text{subject to} && \mu \in \mathbb{R}_+^m, \end{aligned}$$

then the solution u_λ of the corresponding problem (P_λ) is a solution of Problem (P) .

- (2) Assume Problem (P) has some solution $u \in U$, and that Ω is convex (open), the functions φ_i ($1 \leq i \leq m$) and J are convex and differentiable at u , and that the constraints are qualified. Then Problem (D) has a solution $\lambda \in \mathbb{R}_+^m$, and $J(u) = G(\lambda)$; that is, the duality gap is zero.

Proof. (1) Our goal is to prove that for any solution λ of Problem (D) , the pair (u_λ, λ) is a saddle point of L . By Theorem 50.15(1), the point $u_\lambda \in U$ is a solution of Problem (P) .

Since $\lambda \in \mathbb{R}_+^m$ is a solution of Problem (D) , by definition of $G(\lambda)$ and since u_λ satisfies Problem (P_λ) , we have

$$G(\lambda) = \inf_{v \in \Omega} L(v, \lambda) = L(u_\lambda, \lambda),$$

which is one of the two equations characterizing a saddle point. In order to prove the second equation characterizing a saddle point,

$$\sup_{\mu \in \mathbb{R}_+^m} L(u_\mu, \mu) = L(u_\lambda, \lambda),$$

we will begin by proving that the function G is differentiable for all $\mu \in \mathbb{R}_+^m$, in order to be able to apply Theorem 40.9 to conclude that since G has a maximum at λ , that is, $-G$ has minimum at λ , then $-G'_\lambda(\mu - \lambda) \geq 0$ for all $\mu \in \mathbb{R}_+^m$. In fact, we prove that

$$G'_\mu(\xi) = \sum_{i=1}^m \xi_i \varphi_i(u_\mu) \quad \text{for all } \xi \in \mathbb{R}^m. \tag{*_{\text{deriv}}}$$

Consider any two points μ and $\mu + \xi$ in \mathbb{R}_+^m . By definition of u_μ we have

$$L(u_\mu, \mu) \leq L(u_{\mu+\xi}, \mu),$$

which means that

$$J(u_\mu) + \sum_{i=1}^m \mu_i \varphi_i(u_\mu) \leq J(u_{\mu+\xi}) + \sum_{i=1}^m \mu_i \varphi_i(u_{\mu+\xi}), \quad (*_1)$$

and since $G(\mu) = L(u_\mu, \mu) = J(u_\mu) + \sum_{i=1}^m \mu_i \varphi_i(u_\mu)$ and $G(\mu + \xi) = L(u_{\mu+\xi}, \mu + \xi) = J(u_{\mu+\xi}) + \sum_{i=1}^m (\mu_i + \xi_i) \varphi_i(u_{\mu+\xi})$, we have

$$G(\mu + \xi) - G(\mu) = J(u_{\mu+\xi}) - J(u_\mu) + \sum_{i=1}^m (\mu_i + \xi_i) \varphi_i(u_{\mu+\xi}) - \sum_{i=1}^m \mu_i \varphi_i(u_\mu). \quad (*_2)$$

Since $(*_1)$ can be written as

$$0 \leq J(u_{\mu+\xi}) - J(u_\mu) + \sum_{i=1}^m \mu_i \varphi_i(u_{\mu+\xi}) - \sum_{i=1}^m \mu_i \varphi_i(u_\mu),$$

by adding $\sum_{i=1}^m \xi_i \varphi_i(u_{\mu+\xi})$ to both sides of the above inequality and using $(*_2)$ we get

$$\sum_{i=1}^m \xi_i \varphi_i(u_{\mu+\xi}) \leq G(\mu + \xi) - G(\mu). \quad (*_3)$$

By definition of $u_{\mu+\xi}$ we have

$$L(u_{\mu+\xi}, \mu + \xi) \leq L(u_\mu, \mu + \xi),$$

which means that

$$J(u_{\mu+\xi}) + \sum_{i=1}^m (\mu_i + \xi_i) \varphi_i(u_{\mu+\xi}) \leq J(u_\mu) + \sum_{i=1}^m (\mu_i + \xi_i) \varphi_i(u_\mu). \quad (*_4)$$

This can be written as

$$J(u_{\mu+\xi}) - J(u_\mu) + \sum_{i=1}^m (\mu_i + \xi_i) \varphi_i(u_{\mu+\xi}) - \sum_{i=1}^m (\mu_i + \xi_i) \varphi_i(u_\mu) \leq 0,$$

and by adding $\sum_{i=1}^m \xi_i \varphi_i(u_\mu)$ to both sides of the above inequality and using $(*_2)$ we get

$$G(\mu + \xi) - G(\mu) \leq \sum_{i=1}^m \xi_i \varphi_i(u_\mu). \quad (*_5)$$

By putting $(*_3)$ and $(*_5)$ together we obtain

$$\sum_{i=1}^m \xi_i \varphi_i(u_{\mu+\xi}) \leq G(\mu + \xi) - G(\mu) \leq \sum_{i=1}^m \xi_i \varphi_i(u_\mu). \quad (*_6)$$

Consequently there is some $\theta \in [0, 1]$ such that

$$\begin{aligned} G(\mu + \xi) - G(\mu) &= (1 - \theta) \left(\sum_{i=1}^m \xi_i \varphi_i(u_\mu) \right) + \theta \left(\sum_{i=1}^m \xi_i \varphi_i(u_{\mu+\xi}) \right) \\ &= \sum_{i=1}^m \xi_i \varphi_i(u_\mu) + \theta \left(\sum_{i=1}^m \xi_i (\varphi_i(u_{\mu+\xi}) - \varphi_i(u_\mu)) \right). \end{aligned}$$

Since by hypothesis the functions $\mu \mapsto u_\mu$ (from \mathbb{R}_+^m to Ω) and $\varphi_i: \Omega \rightarrow \mathbb{R}$ are continuous, for any $\mu \in \mathbb{R}_+^m$ we can write

$$G(\mu + \xi) - G(\mu) = \sum_{i=1}^m \xi_i \varphi_i(u_\mu) + \|\xi\| \epsilon(\xi), \quad \text{with } \lim_{\xi \rightarrow 0} \epsilon(\xi) = 0, \quad (*_7)$$

for any $\|\cdot\|$ norm on \mathbb{R}^m . Equation $(*_7)$ show that G is differentiable for any $\mu \in \mathbb{R}_+^m$, and that

$$G'_\mu(\xi) = \sum_{i=1}^m \xi_i \varphi_i(u_\mu) \quad \text{for all } \xi \in \mathbb{R}^m. \quad (*_8)$$

Actually there is a small problem, namely that the notion of derivative was defined for a function defined on an *open* set, but \mathbb{R}_+^m is not open. The difficulty only arises to ensure that the derivative is unique, but in our case we have a unique expression for the derivative so there is no problem as far as defining the derivative. There is still a potential problem, which is that we would like to apply Theorem 40.9 to conclude that since G has a maximum at λ , that is, $-G$ has a minimum at λ , then

$$-G'_\lambda(\mu - \lambda) \geq 0 \quad \text{for all } \mu \in \mathbb{R}_+^m, \quad (*_9)$$

but the hypotheses of Theorem 40.9 require the domain of the function to be open. Fortunately, close examination of the proof of Theorem 40.9 shows that the proof still holds with $U = \mathbb{R}_+^m$. Therefore, $(*_8)$ holds, Theorem 40.9 is valid, which in turn implies

$$G'_\lambda(\mu - \lambda) \leq 0 \quad \text{for all } \mu \in \mathbb{R}_+^m, \quad (*_{10})$$

which, using the expression for G'_λ given in $(*_8)$ gives

$$\sum_{i=1}^m \mu_i \varphi_i(u_\lambda) \leq \sum_{i=1}^m \lambda_i \varphi_i(u_\lambda), \quad \text{for all } \mu \in \mathbb{R}_+^m. \quad (*_{11})$$

As a consequence of $(*_\text{11})$, we obtain

$$\begin{aligned} L(u_\lambda, \mu) &= J(u_\lambda) + \sum_{i=1}^m \mu_i \varphi_i(u_\lambda) \\ &\leq J(u_\lambda) + \sum_{i=1}^m \lambda_i \varphi_i(u_\lambda) = L(u_\lambda, \lambda), \end{aligned}$$

for all $\mu \in \mathbb{R}_+^m$, that is,

$$L(u_\lambda, \mu) \leq L(u_\lambda, \lambda), \quad \text{for all } \mu \in \mathbb{R}_+^m, \quad (*_{12})$$

which implies the second inequality

$$\sup_{\mu \in \mathbb{R}_+^m} L(u_\mu, \mu) = L(u_\lambda, \lambda)$$

stating that (u_λ, λ) is a saddle point. Therefore, (u_λ, λ) is a saddle point of L , as claimed.

(2) The hypotheses are exactly those required by Theorem 50.15(2), thus there is some $\lambda \in \mathbb{R}_+^m$ such that (u, λ) is a saddle point of the Lagrangian L , and by Theorem 50.15(1) we have $J(u) = L(u, \lambda)$. By Proposition 50.14, we have

$$J(u) = L(u, \lambda) = \inf_{v \in \Omega} L(v, \lambda) = \sup_{\mu \in \mathbb{R}_+^m} \inf_{v \in \Omega} L(v, \mu),$$

which can be rewritten as

$$J(u) = G(\lambda) = \sup_{\mu \in \mathbb{R}_+^m} G(\mu).$$

In other words, Problem (D) has a solution, and $J(u) = G(\lambda)$. \square

Remark: Note that Theorem 50.17(2) could have already been obtained as a consequence of Theorem 50.15(2), but the dual function G was not yet defined. If (u, λ) is a saddle point of the Lagrangian L (defined on $\Omega \times \mathbb{R}_+^m$), then by Proposition 50.14, the vector λ is a solution of Problem (D) . Conversely, under the hypotheses of Part (1) of Theorem 50.17, if λ is a solution of Problem (D) , then (u_λ, λ) is a saddle point of L . *Consequently, under the above hypotheses, the set of solutions of the Dual Problem (D) coincide with the set of second arguments λ of the saddle points (u, λ) of L .* In some sense, this result is the “dual” of the result stated in Theorem 50.15, namely that the set of solutions of Problem (P) coincides with set of first arguments u of the saddle points (u, λ) of L .

Informally, in Theorem 50.17(1), the hypotheses say that if $G(\mu)$ can be “computed nicely,” in the sense that there is a unique minimizer u_μ of $L(v, \mu)$ (with $v \in \Omega$) such that $G(\mu) = L(u_\mu, \mu)$, and if a maximizer λ of $G(\mu)$ (with $\mu \in \mathbb{R}_+^m$) can be determined, then u_λ yields the minimum value of J , that is, $p^* = J(u_\lambda)$. If the constraints are qualified and if the functions J and φ_i are convex and differentiable, then since the KKT conditions hold, the duality gap is zero; that is,

$$G(\lambda) = L(u_\lambda, \lambda) = J(u_\lambda).$$

Example 50.6. Going back to Example 50.5 where we considered the linear program (P)

$$\begin{aligned} & \text{minimize} && c^\top v \\ & \text{subject to} && Av \leq b, \quad v \geq 0, \end{aligned}$$

with A an $m \times n$ matrix, the Lagrangian $L(v, \mu, \nu)$ is given by

$$L(v, \mu, \nu) = -b^\top \mu + (c + A^\top \mu - \nu)^\top v,$$

and we found that the dual function $G(\mu, \nu) = \inf_{v \in \mathbb{R}^n} L(v, \mu, \nu)$ is given for all $\mu \geq 0$ and $\nu \geq 0$ by

$$G(\mu, \nu) = \begin{cases} -b^\top \mu & \text{if } A^\top \mu - \nu + c = 0, \\ -\infty & \text{otherwise.} \end{cases}$$

The hypotheses of Theorem 50.17(1) certainly fail since there are infinitely $u_{\mu, \nu} \in \mathbb{R}^n$ such that $G(\mu, \nu) = \inf_{v \in \mathbb{R}^n} L(v, \mu, \nu) = L(u_{\mu, \nu}, \mu, \nu)$. Therefore, the dual function G is no help in finding a solution of the Primal Problem (P) . As we saw earlier, if we consider the modified dual Problem (D_1) then strong duality holds, but this *does not* follow from Theorem 50.17, and a different proof is required.

Thus, we have the somewhat counter-intuitive situation that the *general* theory of Lagrange duality does not apply, at least directly, to linear programming, a fact that is not sufficiently emphasized in many expositions. A separate treatment of duality is required.

Unlike the case of linear programming, which needs a separate treatment, Theorem 50.17 applies to the optimization problem involving a convex quadratic objective function and a set of affine inequality constraints. So in some sense, convex quadratic programming is simpler than linear programming!

Example 50.7. Consider the quadratic objective function

$$J(v) = \frac{1}{2}v^\top Av - v^\top b,$$

where A is an $n \times n$ matrix which is symmetric positive definite, $b \in \mathbb{R}^n$, and the constraints are affine inequality constraints of the form

$$Cv \leq d,$$

where C is an $m \times n$ matrix and $d \in \mathbb{R}^m$. For the time being, we do not assume that C has rank m . Since A is symmetric positive definite, J is strictly convex, as implied by Proposition 40.11 (see Example 40.6). The Lagrangian of this quadratic optimization problem is given by

$$\begin{aligned} L(v, \mu) &= \frac{1}{2}v^\top Av - v^\top b + (Cv - d)^\top \mu \\ &= \frac{1}{2}v^\top Av - v^\top(b - C^\top \mu) - \mu^\top d. \end{aligned}$$

Since A is symmetric positive definite, by Proposition 42.2, the function $v \mapsto L(v, \mu)$ has a unique minimum obtained for the solution u_μ of the linear system

$$Av = b - C^\top \mu;$$

that is,

$$u_\mu = A^{-1}(b - C^\top \mu).$$

This shows that the Problem (P_μ) has a unique solution which depends continuously on μ . Then for any solution λ of the dual problem, $u_\lambda = A^{-1}(b - C^\top \lambda)$ is an optimal solution of the primal problem.

We compute $G(\mu)$ as follows:

$$\begin{aligned} G(\mu) &= L(u_\mu, \mu) = \frac{1}{2} u_\mu^\top A u_\mu - u_\mu^\top (b - C^\top \mu) - \mu^\top d \\ &= \frac{1}{2} u_\mu^\top (b - C^\top \mu) - u_\mu^\top (b - C^\top \mu) - \mu^\top d \\ &= -\frac{1}{2} u_\mu^\top (b - C^\top \mu) - \mu^\top d \\ &= -\frac{1}{2} (b - C^\top \mu)^\top A^{-1} (b - C^\top \mu) - \mu^\top d \\ &= -\frac{1}{2} \mu^\top C A^{-1} C^\top \mu + \mu^\top (C A^{-1} b - d) - \frac{1}{2} b^\top A^{-1} b. \end{aligned}$$

Since A is symmetric positive definite, the matrix $C A^{-1} C^\top$ is symmetric positive semidefinite. Since A^{-1} is also symmetric positive definite, $\mu^\top C A^{-1} C^\top \mu = 0$ iff $(C^\top \mu)^\top A^{-1} (C^\top \mu) = 0$ iff $C^\top \mu = 0$ implies $\mu = 0$, that is, $\text{Ker } C^\top = (0)$, which is equivalent to $\text{Im}(C) = \mathbb{R}^m$, namely if C has rank m (in which case, $m \leq n$). Thus $C A^{-1} C^\top$ is symmetric positive definite iff C has rank m .

We showed just after Theorem 49.8 that the functional $v \mapsto (1/2)v^\top A v$ is elliptic iff A is symmetric positive definite, and Theorem 49.8 shows that an elliptic functional is coercive, which is the hypothesis used in Theorem 49.4. Therefore, by Theorem 49.4, if the inequalities $Cx \leq d$ have a solution, the primal problem has a unique solution. In this case, as a consequence, by Theorem 50.17(2), the function $-G(\mu)$ always has a minimum, which is unique if C has rank m . The fact that $-G(\mu)$ has a minimum is not obvious when C has rank $< m$, since in this case $C A^{-1} C^\top$ is not invertible.

We also verify easily that the gradient of G is given by

$$\nabla G_\mu = C u_\mu - d = -C A^{-1} C^\top \mu + C A^{-1} b - d.$$

Observe that since $C A^{-1} C^\top$ is symmetric positive semidefinite, $-G(\mu)$ is convex.

Therefore, if C has rank m , a solution of Problem (P) is obtained by finding the unique solution λ of the equation

$$-C A^{-1} C^\top \mu + C A^{-1} b - d = 0,$$

and then the minimum u_λ of Problem (P) is given by

$$u_\lambda = A^{-1}(b - C^\top \lambda).$$

If C has rank $< m$, then we can find $\lambda \geq 0$ by finding a feasible solution of the linear program whose set of constraints is given by

$$-CA^{-1}C^\top \mu + CA^{-1}b - d = 0,$$

using the standard method of adding nonnegative slack variables ξ_1, \dots, ξ_m and maximizing $-(\xi_1 + \dots + \xi_m)$.

50.9 Handling Equality Constraints Explicitly

Sometimes it is desirable to handle equality constraints explicitly (for instance, this is what Boyd and Vandenberghe do, see [29]). The only difference is that the Lagrange multipliers associated with *equality constraints* are *not required* to be nonnegative, as we now show.

Consider the *Optimization Problem* (P')

$$\begin{aligned} & \text{minimize} && J(v) \\ & \text{subject to} && \varphi_i(v) \leq 0, \quad i = 1, \dots, m \\ & && \psi_j(v) = 0, \quad j = 1, \dots, p. \end{aligned}$$

We treat each equality constraint $\psi_j(u) = 0$ as the conjunction of the inequalities $\psi_j(u) \leq 0$ and $-\psi_j(u) \leq 0$, and we associate Lagrange multipliers $\lambda \in \mathbb{R}_+^m$, and $\nu^+, \nu^- \in \mathbb{R}_+^p$. Assuming that the constraints are qualified, by Theorem 50.5, the KKT conditions are

$$J'_u + \sum_{i=1}^m \lambda_i (\varphi'_i)_u + \sum_{j=1}^p \nu_j^+ (\psi'_j)_u - \sum_{j=1}^p \nu_j^- (\psi'_j)_u = 0,$$

and

$$\sum_{i=1}^m \lambda_i \varphi_i(u) + \sum_{j=1}^p \nu_j^+ \psi_j(u) - \sum_{j=1}^p \nu_j^- \psi_j(u) = 0,$$

with $\lambda \geq 0, \nu^+ \geq 0, \nu^- \geq 0$. Since $\psi_j(u) = 0$ for $j = 1, \dots, p$, these equations can be rewritten as

$$J'_u + \sum_{i=1}^m \lambda_i (\varphi'_i)_u + \sum_{j=1}^p (\nu_j^+ - \nu_j^-) (\psi'_j)_u = 0,$$

and

$$\sum_{i=1}^m \lambda_i \varphi_i(u) = 0$$

with $\lambda \geq 0, \nu^+ \geq 0, \nu^- \geq 0$, and if we introduce $\nu_j = \nu_j^+ - \nu_j^-$ we obtain the following KKT conditions for programs with explicit equality constraints:

$$J'_u + \sum_{i=1}^m \lambda_i (\varphi'_i)_u + \sum_{j=1}^p \nu_j (\psi'_j)_u = 0,$$

and

$$\sum_{i=1}^m \lambda_i \varphi_i(u) = 0$$

with $\lambda \geq 0$ and $\nu \in \mathbb{R}^p$ arbitrary.

Let us now assume that the functions φ_i and ψ_j are *convex*. As we explained just after Definition 50.6, nonaffine equality constraints are never qualified. Thus, in order to generalize Theorem 50.6 to explicit equality constraints, we assume that the *equality constraints* ψ_j are *affine*.

Theorem 50.18. *Let $\varphi_i: \Omega \rightarrow \mathbb{R}$ be m convex inequality constraints and $\psi_j: \Omega \rightarrow \mathbb{R}$ be p affine equality constraints defined on some open convex subset Ω of a finite-dimensional Euclidean vector space V (more generally, a real Hilbert space V), let $J: \Omega \rightarrow \mathbb{R}$ be some function, let U be given by*

$$U = \{x \in \Omega \mid \varphi_i(x) \leq 0, \psi_j(x) = 0, 1 \leq i \leq m, 1 \leq j \leq p\},$$

and let $u \in U$ be any point such that the functions φ_i and J are differentiable at u , and the functions ψ_j are affine.

- (1) If J has a local minimum at u with respect to U , and if the constraints are qualified, then there exist some vectors $\lambda \in \mathbb{R}_+^m$ and $\nu \in \mathbb{R}^p$, such that the KKT condition hold:

$$J'_u + \sum_{i=1}^m \lambda_i(u) (\varphi'_i)_u + \sum_{j=1}^p \nu_j (\psi'_j)_u = 0,$$

and

$$\sum_{i=1}^m \lambda_i(u) \varphi_i(u) = 0, \quad \lambda_i \geq 0, \quad i = 1, \dots, m.$$

Equivalently, in terms of gradients, the above conditions are expressed as

$$\nabla J_u + \sum_{i=1}^m \lambda_i \nabla (\varphi_i)_u + \sum_{j=1}^p \nu_j \nabla (\psi_j)_u = 0$$

and

$$\sum_{i=1}^m \lambda_i(u) \varphi_i(u) = 0, \quad \lambda_i \geq 0, \quad i = 1, \dots, m.$$

- (2) Conversely, if the restriction of J to U is convex and if there exist vectors $\lambda \in \mathbb{R}_+^m$ and $\nu \in \mathbb{R}^p$ such that the KKT conditions hold, then the function J has a (global) minimum at u with respect to U .

The Lagrangian $L(v, \lambda, \nu)$ of Problem (P') is defined as

$$L(v, \mu, \nu) = J(v) + \sum_{i=1}^m \mu_i \varphi_i(v) + \sum_{j=1}^p \nu_j \psi_j(v),$$

where $v \in \Omega$, $\mu \in \mathbb{R}_+^m$, and $\nu \in \mathbb{R}^p$.

The function $G: \mathbb{R}_+^m \times \mathbb{R}^p \rightarrow \mathbb{R}$ given by

$$G(\mu, \nu) = \inf_{v \in \Omega} L(v, \mu, \nu) \quad \mu \in \mathbb{R}_+^m, \nu \in \mathbb{R}^p$$

is called the *Lagrange dual function* (or *dual function*), and the *Dual Problem (D')* is

$$\begin{aligned} & \text{maximize} \quad G(\mu, \nu) \\ & \text{subject to} \quad \mu \in \mathbb{R}_+^m, \nu \in \mathbb{R}^p. \end{aligned}$$

Observe that the Lagrange multipliers ν are not restricted to be nonnegative.

Theorem 50.15 and Theorem 50.17 are immediately generalized to Problem (P') . We only state the new version of 50.17, leaving the new version of Theorem 50.15 as an exercise.

Theorem 50.19. Consider the minimization problem (P') :

$$\begin{aligned} & \text{minimize} \quad J(v) \\ & \text{subject to} \quad \varphi_i(v) \leq 0, \quad i = 1, \dots, m \\ & \quad \psi_j(v) = 0, \quad j = 1, \dots, p. \end{aligned}$$

where the functions J , φ_i are defined on some open subset Ω of a finite-dimensional Euclidean vector space V (more generally, a real Hilbert space V), and the functions ψ_j are affine.

- (1) Suppose the functions $\varphi_i: \Omega \rightarrow \mathbb{R}$ are continuous, and that for every $\mu \in \mathbb{R}_+^m$ and every $\nu \in \mathbb{R}^p$, the Problem $(P_{\mu, \nu})$:

$$\begin{aligned} & \text{minimize} \quad L(v, \mu, \nu) \\ & \text{subject to} \quad v \in \Omega, \end{aligned}$$

has a unique solution $u_{\mu, \nu}$, so that

$$L(u_{\mu, \nu}, \mu, \nu) = \inf_{v \in \Omega} L(v, \mu, \nu) = G(\mu, \nu),$$

and the function $(\mu, \nu) \mapsto u_{\mu, \nu}$ is continuous (on $\mathbb{R}_+^m \times \mathbb{R}^p$). Then the function G is differentiable for all $\mu \in \mathbb{R}_+^m$ and all $\nu \in \mathbb{R}^p$, and

$$G'_{\mu, \nu}(\xi, \zeta) = \sum_{i=1}^m \xi_i \varphi_i(u_{\mu, \nu}) + \sum_{j=1}^p \zeta_j \psi_j(u_{\mu, \nu}) \quad \text{for all } \xi \in \mathbb{R}^m \text{ and all } \zeta \in \mathbb{R}^p.$$

If (λ, η) is any solution of Problem (D):

$$\begin{aligned} & \text{maximize} && G(\mu, \nu) \\ & \text{subject to} && \mu \in \mathbb{R}_+^m, \nu \in \mathbb{R}^p, \end{aligned}$$

then the solution $u_{\lambda, \eta}$ of the corresponding Problem $(P_{\lambda, \eta})$ is a solution of Problem (P') .

- (2) Assume Problem (P') has some solution $u \in U$, and that Ω is convex (open), the functions φ_i ($1 \leq i \leq m$) and J are convex, differentiable at u , and that the constraints are qualified. Then Problem (D') has a solution $(\lambda, \eta) \in \mathbb{R}_+^m \times \mathbb{R}^p$, and $J(u) = G(\lambda, \eta)$; that is, the duality gap is zero.

In the next section we derive the dual function and the dual program of the optimization problem of Section 50.6 (Hard margin SVM), which involves both inequality and equality constraints. We also derive the KKT conditions associated with the dual program.

50.10 Dual of the Hard Margin Support Vector Machine

Recall the **Hard margin SVM** problem (SVM _{h_2}):

$$\begin{aligned} & \text{minimize} && \frac{1}{2} \|w\|^2, \quad w \in \mathbb{R}^n \\ & \text{subject to} && w^\top u_i - b \geq 1 \quad i = 1, \dots, p \\ & && -w^\top v_j + b \geq 1 \quad j = 1, \dots, q. \end{aligned}$$

We proceed in six steps.

Step 1: Write the constraints in matrix form.

The inequality constraints are written as

$$C \begin{pmatrix} w \\ b \end{pmatrix} \leq d,$$

where C is a $(p+q) \times (n+1)$ matrix C and $d \in \mathbb{R}^{p+q}$ is the vector given by

$$C = \begin{pmatrix} -u_1^\top & 1 \\ \vdots & \vdots \\ -u_p^\top & 1 \\ v_1^\top & -1 \\ \vdots & \vdots \\ v_q^\top & -1 \end{pmatrix}, \quad d = \begin{pmatrix} -1 \\ \vdots \\ -1 \end{pmatrix} = -\mathbf{1}_{p+q}.$$

If we let X be the $n \times (p+q)$ matrix given by

$$X = (-u_1 \ \cdots \ -u_p \ \ v_1 \ \cdots \ \ v_q),$$

then

$$C = \begin{pmatrix} X^\top & \mathbf{1}_p \\ -\mathbf{1}_q & \end{pmatrix}$$

and so

$$C^\top = \begin{pmatrix} X & \\ \mathbf{1}_p^\top & -\mathbf{1}_q^\top \end{pmatrix}.$$

Step 2: Write the objective function in matrix form.

The objective function is given by

$$J(w, b) = \frac{1}{2} (w^\top \ b) \begin{pmatrix} I_n & 0_n \\ 0_n^\top & 0 \end{pmatrix} \begin{pmatrix} w \\ b \end{pmatrix}.$$

Note that the corresponding matrix is symmetric positive semidefinite, but it is *not* invertible. Thus the function J is convex but not strictly convex.

Step 3: Write the Lagrangian in matrix form.

As in Example 50.7, we obtain the Lagrangian

$$L(w, b, \lambda, \mu) = \frac{1}{2} (w^\top \ b) \begin{pmatrix} I_n & 0_n \\ 0_n^\top & 0 \end{pmatrix} \begin{pmatrix} w \\ b \end{pmatrix} - (w^\top \ b) \left(0_{n+1} - C^\top \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \right) + (\lambda^\top \ \mu^\top) \mathbf{1}_{p+q},$$

that is,

$$L(w, b, \lambda, \mu) = \frac{1}{2} (w^\top \ b) \begin{pmatrix} I_n & 0_n \\ 0_n^\top & 0 \end{pmatrix} \begin{pmatrix} w \\ b \end{pmatrix} + (w^\top \ b) \begin{pmatrix} X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ \mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu \end{pmatrix} + (\lambda^\top \ \mu^\top) \mathbf{1}_{p+q}.$$

Step 4: Find the dual function $G(\lambda, \mu)$.

In order to find the dual function $G(\lambda, \mu)$, we need to minimize $L(w, b, \lambda, \mu)$ with respect to w and b and for this, since the objective function J is convex and since \mathbb{R}^{n+1} is convex

and open, we can apply Theorem 40.13, which gives a necessary and sufficient condition for a minimum. The gradient of $L(w, b, \lambda, \mu)$ with respect to w and b is

$$\begin{aligned}\nabla L_{w,b} &= \begin{pmatrix} I_n & 0_n \\ 0_n^\top & 0 \end{pmatrix} \begin{pmatrix} w \\ b \end{pmatrix} + \begin{pmatrix} X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ \mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu \end{pmatrix} \\ &= \begin{pmatrix} w \\ 0 \end{pmatrix} + \begin{pmatrix} X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ \mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu \end{pmatrix}.\end{aligned}$$

The necessary and sufficient condition for a minimum is

$$\nabla L_{w,b} = 0,$$

which yields

$$w = -X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \quad (*_1)$$

and

$$\mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu = 0. \quad (*_2)$$

The second equation can be written as

$$\sum_{i=1}^p \lambda_i = \sum_{j=1}^q \mu_j. \quad (*_3)$$

Plugging back w from $(*_1)$ into the Lagrangian and using $(*_2)$ we get

$$G(\lambda, \mu) = -\frac{1}{2} (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + (\lambda^\top \mu^\top) \mathbf{1}_{p+q}; \quad (*_4)$$

of course, $(\lambda^\top \mu^\top) \mathbf{1}_{p+q} = \sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j$. Actually, to be perfectly rigorous $G(\lambda, \mu)$ is only defined on the intersection of the hyperplane of equation $\sum_{i=1}^p \lambda_i = \sum_{j=1}^q \mu_j$ with the convex octant in \mathbb{R}^{p+q} given by $\lambda \geq 0, \mu \geq 0$, so for all $\lambda \in \mathbb{R}_+^p$ and all $\mu \in \mathbb{R}_+^q$, we have

$$G(\lambda, \mu) = \begin{cases} -\frac{1}{2} (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + (\lambda^\top \mu^\top) \mathbf{1}_{p+q} & \text{if } \sum_{i=1}^p \lambda_i = \sum_{j=1}^q \mu_j \\ -\infty & \text{otherwise.} \end{cases}$$

Note that the condition

$$\sum_{i=1}^p \lambda_i = \sum_{j=1}^q \mu_j$$

is Condition $(*_2)$ of Example 50.6, which is not surprising.

Step 5: Write the dual program in matrix form.

Maximizing the dual function $G(\lambda, \mu)$ over its domain of definition is equivalent to maximizing

$$\widehat{G}(\lambda, \mu) = -\frac{1}{2} (\lambda^\top \ \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + (\lambda^\top \ \mu^\top) \mathbf{1}_{p+q}$$

subject to the constraint

$$\sum_{i=1}^p \lambda_i = \sum_{j=1}^q \mu_j,$$

so we formulate the dual program as,

$$\text{maximize } -\frac{1}{2} (\lambda^\top \ \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + (\lambda^\top \ \mu^\top) \mathbf{1}_{p+q}$$

subject to

$$\sum_{i=1}^p \lambda_i = \sum_{j=1}^q \mu_j$$

$$\lambda \geq 0, \ \mu \geq 0,$$

or equivalently,

$$\text{minimize } \frac{1}{2} (\lambda^\top \ \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - (\lambda^\top \ \mu^\top) \mathbf{1}_{p+q}$$

subject to

$$\sum_{i=1}^p \lambda_i = \sum_{j=1}^q \mu_j$$

$$\lambda \geq 0, \ \mu \geq 0.$$

The constraints of the dual program are a lot simpler than the constraints

$$\begin{pmatrix} X^\top & \mathbf{1}_p \\ -\mathbf{1}_q & \end{pmatrix} \begin{pmatrix} w \\ b \end{pmatrix} \leq -\mathbf{1}_{p+q}$$

of the primal program because these constraints have been “absorbed” by the objective function $\widehat{G}(\lambda, \nu)$ of the dual program which involves the matrix $X^\top X$. The matrix $X^\top X$ is symmetric positive semidefinite, but not invertible in general.

Step 6: Solve the dual program.

This step involves using numerical procedures typically based on gradient descent to find λ and μ , for example, ADMM from Section 52.6. Once λ and μ are determined, w is determined by $(*_1)$ and b is determined as in Section 50.6 using the fact that there is at least some i_0 such that $\lambda_{i_0} > 0$ and some j_0 such that $\mu_{j_0} > 0$.

Remarks:

- (1) Since the constraints are affine and the objective function is convex, by Theorem 50.19(2) the duality gap is zero, so for any minimum w of $J(w, b) = (1/2)w^\top w$ and any maximum (λ, μ) of G , we have

$$J(w, b) = \frac{1}{2}w^\top w = G(\lambda, \mu).$$

But by $(*_1)$

$$w = -X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = \sum_{i=1}^p \lambda_i u_i - \sum_{j=1}^q \mu_j v_j,$$

so

$$(\lambda^\top \ \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = w^\top w,$$

and we get

$$\frac{1}{2}w^\top w = -\frac{1}{2}(\lambda^\top \ \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + (\lambda^\top \ \mu^\top) \mathbf{1}_{p+q} = -\frac{1}{2}w^\top w + (\lambda^\top \ \mu^\top) \mathbf{1}_{p+q},$$

so

$$w^\top w = (\lambda^\top \ \mu^\top) \mathbf{1}_{p+q} = \sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j,$$

which yields

$$G(\lambda, \mu) = \frac{1}{2} \left(\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j \right).$$

The above formulae are stated in Vapnik [182] (Chapter 10, Section 1).

- (2) It is instructive to compute the Lagrangian of the dual program and to derive the KKT conditions for this Lagrangian.

The conditions $\lambda \geq 0$ being equivalent to $-\lambda \leq 0$, and the conditions $\mu \geq 0$ being equivalent to $-\mu \leq 0$, we introduce Lagrange multipliers $\alpha \in \mathbb{R}_+^p$ and $\beta \in \mathbb{R}_+^q$ as well as a multiplier $\rho \in \mathbb{R}$ for the equational constraint, and we form the Lagrangian

$$\begin{aligned} L(\lambda, \mu, \alpha, \beta, \rho) &= \frac{1}{2}(\lambda^\top \ \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - (\lambda^\top \ \mu^\top) \mathbf{1}_{p+q} \\ &\quad - \sum_{i=1}^p \alpha_i \lambda_i - \sum_{j=1}^q \beta_j \mu_j + \rho \left(\sum_{j=1}^q \mu_j - \sum_{i=1}^p \lambda_i \right). \end{aligned}$$

It follows that the KKT conditions are

$$X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - \mathbf{1}_{p+q} - \begin{pmatrix} \alpha \\ \beta \end{pmatrix} + \rho \begin{pmatrix} -\mathbf{1}_p \\ \mathbf{1}_q \end{pmatrix} = \mathbf{0}_{p+q}, \quad (*_4)$$

and $\alpha_i \lambda_i = 0$ for $i = 1, \dots, p$ and $\beta_j \mu_j = 0$ for $j = 1, \dots, q$.

But $(*_4)$ is equivalent to

$$-X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + \rho \begin{pmatrix} \mathbf{1}_p \\ -\mathbf{1}_q \end{pmatrix} + \mathbf{1}_{p+q} + \begin{pmatrix} \alpha \\ \beta \end{pmatrix} = \mathbf{0}_{p+q},$$

which is precisely the result of adding $\alpha \geq 0$ and $\beta \geq 0$ as slack variables to the inequalities $(*_3)$ of Example 50.6, namely

$$-X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + b \begin{pmatrix} \mathbf{1}_p \\ -\mathbf{1}_q \end{pmatrix} + \mathbf{1}_{p+q} \leq \mathbf{0}_{p+q},$$

to make them equalities, where ρ plays the role of b .

When the constraints are *affine*, the dual function $G(\lambda, \nu)$ can be expressed in terms of the conjugate of the objective function J .

50.11 Conjugate Function and Legendre Dual Function

The notion of conjugate function goes back to Legendre and plays an important role in classical mechanics for converting a Lagrangian to a Hamiltonian; see Arnold [5] (Chapter 3, Sections 14 and 15).

Definition 50.11. Let $f: A \rightarrow \mathbb{R}$ be a function defined on some subset A of \mathbb{R}^n . The *conjugate* f^* of the function f is the partial function $f^*: \mathbb{R}^n \rightarrow \mathbb{R}$ defined by

$$f^*(y) = \sup_{x \in A} (\langle y, x \rangle - f(x)) = \sup_{x \in A} (y^\top x - f(x)), \quad y \in \mathbb{R}^n.$$

The conjugate of a function is also called the *Fenchel conjugate*, or *Legendre transform* when f is differentiable.

As the pointwise supremum of a family of affine functions in y , the conjugate function f^* is *convex*, even if the original function f is not convex.

By definition of f^* we have

$$f(x) + f^*(y) \geq \langle x, y \rangle = x^\top y,$$

whenever the left-hand side is defined. The above is known as *Fenchel's inequality* (or *Young's inequality* if f is differentiable).

If $f: A \rightarrow \mathbb{R}$ is convex (so A is convex) and if $\text{epi}(f)$ is closed, then it can be shown that $f^{**} = f$. In particular, this is true if $A = \mathbb{R}^n$.

The domain of f^* can be very small, even if the domain of f is big. For example, if $f: \mathbb{R} \rightarrow \mathbb{R}$ is the affine function given by $f(x) = ax + b$ (with $a, b \in \mathbb{R}$), then the function $x \mapsto yx - ax - b$ is unbounded above unless $y = a$, so

$$f^*(y) = \begin{cases} -b & \text{if } y = a \\ +\infty & \text{otherwise.} \end{cases}$$

The domain of f^* can also be bigger than the domain of f ; see Example 50.8(3).

The conjugates of many functions that come up in optimization are derived in Boyd and Vandenberghe; see [29], Section 3.3. We mention a few that will be used in this chapter.

Example 50.8.

- (1) *Negative logarithm:* $f(x) = -\log x$, with $\text{dom}(f) = \{x \in \mathbb{R} \mid x > 0\}$. The function $x \mapsto yx + \log x$ is unbounded above if $y \geq 0$, and when $y < 0$, its maximum is obtained iff its derivative is zero, namely

$$y + \frac{1}{x} = 0.$$

Substituting for $x = -1/y$ in $yx + \log x$, we obtain $-1 + \log(-1/y) = -1 - \log(-y)$, so we have

$$f^*(y) = -\log(-y) - 1,$$

with $\text{dom}(f^*) = \{y \in \mathbb{R} \mid y < 0\}$.

- (2) *Exponential:* $f(x) = e^x$, with $\text{dom}(f) = \mathbb{R}$. The function $x \mapsto yx - e^x$ is unbounded if $y < 0$. When $y > 0$, it reaches a maximum iff its derivative is zero, namely

$$y - e^x = 0.$$

Substituting for $x = \log y$ in $yx - e^x$, we obtain $y \log y - y$, so we have

$$f^*(y) = y \log y - y,$$

with $\text{dom}(f^*) = \{y \in \mathbb{R} \mid y \geq 0\}$, with the convention that $0 \log 0 = 0$.

- (3) *Negative Entropy:* $f(x) = x \log x$, with $\text{dom}(f) = \{x \in \mathbb{R} \mid x \geq 0\}$, with the convention that $0 \log 0 = 0$. The function $x \mapsto yx - x \log x$ is bounded above for all $y > 0$, and it attains its maximum when its derivative is zero, namely

$$y - \log x - 1 = 0.$$

Substituting for $x = e^{y-1}$ in $yx - x \log x$, we obtain $ye^{y-1} - e^{y-1}(y-1) = e^{y-1}$, which yields

$$f^*(y) = e^{y-1},$$

with $\text{dom}(f^*) = \mathbb{R}$.

- (4) *Strictly convex quadratic function:* $f(x) = \frac{1}{2}x^\top Ax$, where A is an $n \times n$ symmetric positive definite matrix, with $\text{dom}(f) = \mathbb{R}^n$. The function $x \mapsto y^\top x - \frac{1}{2}x^\top Ax$ has a unique maximum when its gradient is zero, namely

$$y = Ax.$$

Substituting for $x = A^{-1}y$ in $y^\top x - \frac{1}{2}x^\top Ax$, we obtain

$$y^\top A^{-1}y - \frac{1}{2}y^\top A^{-1}y = -\frac{1}{2}y^\top A^{-1}y,$$

so

$$f^*(y) = -\frac{1}{2}y^\top A^{-1}y$$

with $\text{dom}(f^*) = \mathbb{R}^n$.

- (5) *Log-determinant:* $f(X) = \log \det(X^{-1})$, where X is an $n \times n$ symmetric positive definite matrix. Then

$$f(Y) = \log \det((-Y)^{-1}) - n,$$

where Y is an $n \times n$ symmetric negative definite matrix; see Boyd and Vandenberghe; see [29], Section 3.3.1, Example 3.23.

- (6) *Norm on \mathbb{R}^n :* $f(x) = \|x\|$ for any norm $\|\cdot\|$ on \mathbb{R}^n , with $\text{dom}(f) = \mathbb{R}^n$. Recall from Section 14.7 that the dual norm $\|\cdot\|^D$ of the norm $\|\cdot\|$ (with respect to the canonical inner product $x \cdot y = y^\top x$ on \mathbb{R}^n) is given by

$$\|y\|^D = \sup_{\|x\|=1} |y^\top x|,$$

and that

$$|y^\top x| \leq \|x\| \|y\|^D.$$

We have

$$\begin{aligned} f^*(y) &= \sup_{x \in \mathbb{R}^n} (y^\top x - \|x\|) \\ &= \sup_{x \in \mathbb{R}^n, x \neq 0} \left(y^\top \frac{x}{\|x\|} - 1 \right) \|x\| \\ &\leq \sup_{x \in \mathbb{R}^n, x \neq 0} (\|y\|^D - 1) \|x\|, \end{aligned}$$

so if $\|y\|^D > 1$ this last term goes to $+\infty$, but if $\|y\|^D \leq 1$, then its maximum is 0. Therefore,

$$f^*(y) = \|y\|^* = \begin{cases} 0 & \text{if } \|y\|^D \leq 1 \\ +\infty & \text{otherwise.} \end{cases}$$

(7) *Norm squared:* $f(x) = \frac{1}{2} \|x\|^2$ for any norm $\|\cdot\|$ on \mathbb{R}^n , with $\text{dom}(f) = \mathbb{R}^n$. Since $|y^\top x| \leq \|x\| \|y\|^D$, we have

$$y^\top x - (1/2) \|x\|^2 \leq \|y\|^D \|x\| - (1/2) \|x\|^2.$$

The right-hand side is a quadratic function of $\|x\|$ which achieves its maximum at $\|x\| = \|y\|^D$, with maximum value $(1/2)(\|y\|^D)^2$. Therefore

$$y^\top x - (1/2) \|x\|^2 \leq (1/2) (\|y\|^D)^2$$

for all x , which shows that

$$f^*(y) \leq (1/2) (\|y\|^D)^2.$$

By definition of the dual norm and because the unit sphere is compact, for any $y \in \mathbb{R}^n$, there is some $x \in \mathbb{R}^n$ such that $\|x\| = 1$ and $y^\top x = \|y\|^D$, so multiplying both sides by $\|y\|^D$ we obtain

$$y^\top \|y\|^D x = (\|y\|^D)^2$$

and for $z = \|y\|^D x$, since $\|x\| = 1$ we have $\|z\| = \|y\|^D \|x\| = \|y\|^D$, so we get

$$y^\top z - (1/2)(\|z\|)^2 = (\|y\|^D)^2 - (1/2) (\|y\|^D)^2 = (1/2) (\|y\|^D)^2,$$

which shows that the upper bound $(1/2) (\|y\|^D)^2$ is achieved. Therefore,

$$f^*(y) = \frac{1}{2} (\|y\|^D)^2,$$

and $\text{dom}(f^*) = \mathbb{R}^n$.

(8) *Log-sum-exp function:* $f(x) = \log\left(\sum_{i=1}^n e^{x_i}\right)$, where $x = (x_1, \dots, x_n) \in \mathbb{R}^n$. To determine the values of $y \in \mathbb{R}^n$ for which the maximum of $g(x) = y^\top x - f(x)$ over $x \in \mathbb{R}^n$ is attained, we compute its gradient and we find

$$\nabla f_x = \begin{pmatrix} y_1 - \frac{e^{x_1}}{\sum_{i=1}^n e^{x_i}} \\ \vdots \\ y_n - \frac{e^{x_n}}{\sum_{i=1}^n e^{x_i}} \end{pmatrix}.$$

Therefore, (y_1, \dots, y_n) must satisfy the system of equations

$$y_j = \frac{e^{x_j}}{\sum_{i=1}^n e^{x_i}}, \quad j = 1, \dots, n. \tag{*}$$

The condition $\sum_{i=1}^n y_i = 1$ is obviously necessary, as well as the conditions $y_i > 0$, for $i = 1, \dots, n$. Conversely, if $\mathbf{1}^\top y = 1$ and $y > 0$, then $x_j = \log y_i$ for $i = 1, \dots, n$ is a solution. Since $(*)$ implies that

$$x_i = \log y_i + \log \left(\sum_{i=1}^n e^{x_i} \right), \quad (**)$$

we get

$$\begin{aligned} y^\top x - f(x) &= \sum_{i=1}^n y_i x_i - \log \left(\sum_{i=1}^n e^{x_i} \right) \\ &= \sum_{i=1}^n y_i \log y_i + \sum_{i=1}^n y_i \log \left(\sum_{i=1}^n e^{x_i} \right) - \log \left(\sum_{i=1}^n e^{x_i} \right) \quad \text{by } (**) \\ &= \sum_{i=1}^n y_i \log y_i + \left(\sum_{i=1}^n y_i - 1 \right) \log \left(\sum_{i=1}^n e^{x_i} \right) \\ &= \sum_{i=1}^n y_i \log y_i \quad \text{since } \sum_{i=1}^n y_i = 1. \end{aligned}$$

Consequently, if $f^*(y)$ is defined, then $f^*(y) = \sum_{i=1}^n y_i \log y_i$. If we agree that $0 \log 0 = 0$, then it is an easy exercise (or, see Boyd and Vandenberghe [29], Section 3.3, Example 3.25) to show that

$$f^*(y) = \begin{cases} \sum_{i=1}^n y_i \log y_i & \text{if } \mathbf{1}^\top y = 1 \text{ and } y \geq 0 \\ \infty & \text{otherwise.} \end{cases}$$

Thus we obtain the negative entropy restricted to the domain $\mathbf{1}^\top y = 1$ and $y \geq 0$.

If $f: \mathbb{R}^n \rightarrow \mathbb{R}$ is convex and differentiable, then x^* maximizes $x^\top y - f(x)$ iff x^* minimizes $-x^\top y + f(x)$ iff

$$\nabla f_{x^*} = y,$$

and so

$$f^*(y) = (x^*)^\top \nabla f_{x^*} - f(x^*).$$

Consequently, if we can solve the equation

$$\nabla f_z = y$$

for z given y , then we obtain $f^*(y)$.

It can be shown that if f is twice differentiable, strictly convex, and surlinear, which means that

$$\lim_{\|y\| \mapsto +\infty} \frac{f(y)}{\|y\|} = +\infty,$$

then there is a unique x_y such that $\nabla f_{x_y} = y$, so that

$$f^*(y) = x_y^\top \nabla f_{x_y} - f(x_y),$$

and f^* is differentiable with

$$\nabla f_y^* = x_y.$$

We now return to our optimization problem.

Proposition 50.20. *Consider Problem (P),*

$$\begin{aligned} & \text{minimize} && J(v) \\ & \text{subject to} && Av \leq b \\ & && Cv = d, \end{aligned}$$

with affine inequality and equality constraints (with A an $m \times n$ matrix, C an $p \times n$ matrix, $b \in \mathbb{R}^m$, $d \in \mathbb{R}^p$). The dual function $G(\lambda, \nu)$ is given by

$$G(\lambda, \nu) = \begin{cases} -b^\top \lambda - d^\top \nu - J^*(-A^\top \lambda - C^\top \nu) & \text{if } -A^\top \lambda - C^\top \nu \in \text{dom}(J^*), \\ -\infty & \text{otherwise,} \end{cases}$$

for all $\lambda \in \mathbb{R}_+^m$ and all $\nu \in \mathbb{R}^p$, where J^* is the conjugate of J .

Proof. The Lagrangian associated with the above program is

$$\begin{aligned} L(v, \lambda, \nu) &= J(v) + (Av - b)^\top \lambda + (Cv - d)^\top \nu \\ &= -b^\top \lambda - d^\top \nu + J(v) + (A^\top \lambda + C^\top \nu)^\top v, \end{aligned}$$

with $\lambda \in \mathbb{R}_+^m$ and $\nu \in \mathbb{R}^p$. By definition

$$\begin{aligned} G(\lambda, \nu) &= -b^\top \lambda - d^\top \nu + \inf_{v \in \mathbb{R}^n} (J(v) + (A^\top \lambda + C^\top \nu)^\top v) \\ &= -b^\top \lambda - d^\top \nu - \sup_{v \in \mathbb{R}^n} (-(A^\top \lambda + C^\top \nu)^\top v - J(v)) \\ &= -b^\top \lambda - d^\top \nu - J^*(-A^\top \lambda - C^\top \nu). \end{aligned}$$

Therefore, for all $\lambda \in \mathbb{R}_+^m$ and all $\nu \in \mathbb{R}^p$, we have

$$G(\lambda, \nu) = \begin{cases} -b^\top \lambda - d^\top \nu - J^*(-A^\top \lambda - C^\top \nu) & \text{if } -A^\top \lambda - C^\top \nu \in \text{dom}(J^*), \\ -\infty & \text{otherwise,} \end{cases}$$

as claimed. \square

As application of Proposition 50.20, consider the following example.

Example 50.9. Consider the following problem:

$$\begin{aligned} & \text{minimize} && \|v\| \\ & \text{subject to} && Av = b, \end{aligned}$$

where $\|\cdot\|$ is any norm on \mathbb{R}^n . Using the result of Example 50.8(6), we obtain

$$G(\nu) = -b^\top \nu - \| -A^\top \nu \|^*,$$

that is,

$$G(\nu) = \begin{cases} -b^\top \nu & \text{if } \|A^\top \nu\|^D \leq 1 \\ -\infty & \text{otherwise.} \end{cases}$$

In the special case where $\|\cdot\| = \|\cdot\|_2$, we also have $\|\cdot\|^D = \|\cdot\|_2$.

Another interesting application is to the entropy minimization problem.

Example 50.10. Consider the following problem known as *entropy minimization*:

$$\begin{aligned} & \text{minimize} && f(x) = \sum_{i=1}^n x_i \log x_i \\ & \text{subject to} && Ax \leq b \\ & && \mathbf{1}^\top x = 1, \end{aligned}$$

where $\text{dom}(f) = \{x \in \mathbb{R}^n \mid x \geq 0\}$. By Example 50.8(3), the conjugate of the negative entropy function $u \log u$ is e^{u-1} , so we easily see that

$$f^*(y) = \sum_{i=1}^n e^{y_i - 1},$$

which is defined on \mathbb{R}^n . Proposition 50.20 implies that the dual function $G(\lambda, \mu)$ of the entropy minimization problem is given by

$$G(\lambda, \mu) = -b^\top \lambda - \mu - e^{-\mu-1} \sum_{i=1}^n e^{-(A^i)^\top \lambda},$$

for all $\lambda \in \mathbb{R}_+^n$ and all $\mu \in \mathbb{R}$, where A^i is the i th column of A . It follows that the dual program is:

$$\begin{aligned} & \text{maximize} && -b^\top \lambda - \mu - e^{-\mu-1} \sum_{i=1}^n e^{-(A^i)^\top \lambda} \\ & \text{subject to} && \lambda \geq 0. \end{aligned}$$

We can simplify this problem by maximizing over the variable $\mu \in \mathbb{R}$. For fixed λ , the objective function is maximized when the derivative is zero, that is,

$$-1 + e^{-\mu-1} \sum_{i=1}^n e^{-(A^i)^\top \lambda} = 0,$$

which yields

$$\mu = \log \left(\sum_{i=1}^n e^{-(A^i)^\top \lambda} \right) - 1.$$

By plugging the above value back into the objective function of the dual, we obtain the following program:

$$\begin{aligned} & \text{maximize} && -b^\top \lambda - \log \left(\sum_{i=1}^n e^{-(A^i)^\top \lambda} \right) \\ & \text{subject to} && \lambda \geq 0. \end{aligned}$$

The entropy minimization problem is another problem for which Theorem 50.18 applies, and thus can be solved using the dual program. Indeed, the Lagrangian of the primal program is given by

$$L(x, \lambda, \mu) = \sum_{i=1}^n x_i \log x_i + \lambda^\top (Ax - b) + \mu(\mathbf{1}^\top x - 1).$$

Using the second derivative criterion for convexity, we see that $L(x, \lambda, \mu)$ is strictly convex for $x \in \mathbb{R}_+^n$ and is bounded below, so it has a unique minimum which is obtained by setting the gradient ∇L_x to zero. We have

$$\nabla L_x = \begin{pmatrix} \log x_1 + 1 + (A^1)^\top \lambda + \mu \\ \vdots \\ \log x_n + 1 + (A^n)^\top \lambda + \mu \end{pmatrix}$$

so by setting ∇L_x to 0 we obtain

$$x_i = e^{-(A^n)^\top \lambda + \mu + 1}, \quad i = 1, \dots, n. \quad (*)$$

By Theorem 50.18, since the objective function is convex and the constraints are affine, if the primal has a solution then so does the dual, and λ and μ constitute an optimal solution of the dual, then $x = (x_1, \dots, x_n)$ given by the equations in $(*)$ is an optimal solution of the primal.

Other examples are given in Boyd and Vandenberghe; see [29], Section 5.1.6.

The derivation of the dual function of Problem (SVM_{h1}) from Section 50.5 involves a similar type of reasoning.

Example 50.11. Consider the Hard Margin Problem (SVM_{h1}):

$$\begin{aligned} & \text{maximize} && \delta \\ & \text{subject to} && \\ & w^\top u_i - b \geq \delta && i = 1, \dots, p \\ & -w^\top v_j + b \geq \delta && j = 1, \dots, q \\ & \|w\|_2 \leq 1, \end{aligned}$$

which is converted to the following minimization problem:

$$\begin{aligned} & \text{minimize} && -2\delta \\ & \text{subject to} && \\ & w^\top u_i - b \geq \delta && i = 1, \dots, p \\ & -w^\top v_j + b \geq \delta && j = 1, \dots, q \\ & \|w\|_2 \leq 1. \end{aligned}$$

We replaced δ by 2δ because this will make it easier to find a nice geometric interpretation. Recall from Section 50.5 that Problem (SVM_{h1}) has a an optimal solution iff $\delta > 0$, in which case $\|w\| = 1$.

The corresponding Lagrangian with $\lambda \in \mathbb{R}_+^p, \mu \in \mathbb{R}_+^q, \gamma \in \mathbb{R}^+$, is

$$\begin{aligned} L(w, b, \delta, \lambda, \mu, \gamma) &= -2\delta + \sum_{i=1}^p \lambda_i(\delta + b - w^\top u_i) + \sum_{j=1}^q \mu_j(\delta - b + w^\top v_j) + \gamma(\|w\|_2 - 1) \\ &= w^\top \left(-\sum_{i=1}^p \lambda_i u_i + \sum_{j=1}^q \mu_j v_j \right) + \gamma \|w\|_2 + \left(\sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j \right) b \\ &\quad + \left(-2 + \sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j \right) \delta - \gamma. \end{aligned}$$

Next to find the dual function $G(\lambda, \mu, \gamma)$ we need to minimize $L(w, b, \delta, \lambda, \mu, \gamma)$ with respect to w, b and δ , so its gradient with respect to w, b and δ must be zero. This implies that

$$\begin{aligned} \sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j &= 0 \\ -2 + \sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j &= 0, \end{aligned}$$

which yields

$$\sum_{i=1}^p \lambda_i = \sum_{j=1}^q \mu_j = 1.$$

Observe that we did not compute the partial derivative with respect to w because it does not yield any useful information due to the presence of the term $\|w\|_2$ (as opposed to $\|w\|_2^2$). Our minimization problem is reduced to: find

$$\begin{aligned}
 & \inf_{w, \|w\| \leq 1} \left(w^\top \left(\sum_{j=1}^q \mu_j v_j - \sum_{i=1}^p \lambda_i u_i \right) + \gamma \|w\|_2 - \gamma \right) \\
 &= -\gamma - \gamma \inf_{w, \|w\| \leq 1} \left(-w^\top \frac{1}{\gamma} \left(\sum_{j=1}^q \mu_j v_j - \sum_{i=1}^p \lambda_i u_i \right) + \|w\|_2 \right) \\
 &= \begin{cases} -\gamma & \text{if } \left\| \frac{1}{\gamma} \left(\sum_{j=1}^q \mu_j v_j - \sum_{i=1}^p \lambda_i u_i \right) \right\|_2^D \leq 1 \\ -\infty & \text{otherwise} \end{cases} \quad \text{by Example 50.8(6)} \\
 &= \begin{cases} -\gamma & \text{if } \left\| \sum_{j=1}^q \mu_j v_j - \sum_{i=1}^p \lambda_i u_i \right\|_2 \leq \gamma \\ -\infty & \text{otherwise.} \end{cases} \quad \text{since } \|\cdot\|_2^D = \|\cdot\|_2 \text{ and } \gamma > 0
 \end{aligned}$$

It is immediately verified that the above formula is still correct if $\gamma = 0$. Therefore

$$G(\lambda, \mu, \gamma) = \begin{cases} -\gamma & \text{if } \left\| \sum_{j=1}^q \mu_j v_j - \sum_{i=1}^p \lambda_i u_i \right\|_2 \leq \gamma \\ -\infty & \text{otherwise.} \end{cases}$$

Since $\left\| \sum_{j=1}^q \mu_j v_j - \sum_{i=1}^p \lambda_i u_i \right\|_2 \leq \gamma$ iff $-\gamma \leq -\left\| \sum_{j=1}^q \mu_j v_j - \sum_{i=1}^p \lambda_i u_i \right\|_2$, the dual program, maximizing $G(\lambda, \mu, \gamma)$, is equivalent to

$$\begin{aligned}
 & \text{maximize} \quad - \left\| \sum_{j=1}^q \mu_j v_j - \sum_{i=1}^p \lambda_i u_i \right\|_2 \\
 & \text{subject to}
 \end{aligned}$$

$$\begin{aligned}
 & \sum_{i=1}^p \lambda_i = 1, \quad \lambda \geq 0 \\
 & \sum_{j=1}^q \mu_j = 1, \quad \mu \geq 0,
 \end{aligned}$$

equivalently

$$\text{minimize} \quad \left\| \sum_{j=1}^q \mu_j v_j - \sum_{i=1}^p \lambda_i u_i \right\|_2$$

subject to

$$\sum_{i=1}^p \lambda_i = 1, \quad \lambda \geq 0$$

$$\sum_{j=1}^q \mu_j = 1, \quad \mu \geq 0.$$

Geometrically, $\sum_{i=1}^p \lambda_i u_i$ with $\sum_{i=1}^p \lambda_i = 1$ and $\lambda \geq 0$ is a convex combination of the u_i s, and $\sum_{j=1}^q \mu_j v_j$ with $\sum_{j=1}^q \mu_j = 1$ and $\mu \geq 0$ is a convex combination of the v_j s, so the dual program is to minimize the distance between the polyhedron $\text{conv}(u_1, \dots, u_p)$ (the convex hull of the u_i s) and the polyhedron $\text{conv}(v_1, \dots, v_q)$ (the convex hull of the v_j s). Since both polyhedra are compact, the shortest distance between them is achieved. In fact, there is some vertex u_i such that if $P(u_i)$ is its projection onto $\text{conv}(v_1, \dots, v_q)$ (which exists by Hilbert space theory), then the length of the line segment $(u_i, P(u_i))$ is the shortest distance between the two polyhedra (and similarly there is some vertex v_j such that if $P(v_j)$ is its projection onto $\text{conv}(u_1, \dots, u_p)$ then the length of the line segment $(v_j, P(v_j))$ is the shortest distance between the two polyhedra).

If the two subsets are separable, in which case Problem (SVM_{h1}) has an optimal solution $\delta > 0$, because the objective function is convex and the convex constraint $\|w\|_2 \leq 1$ is qualified since δ may be negative, by Theorem 50.17(2) the duality gap is zero, so δ is half of the minimum distance between the two convex polyhedra $\text{conv}(u_1, \dots, u_p)$ and $\text{conv}(v_1, \dots, v_q)$; see Figure 50.19.

It should be noted that the constraint $\|w\| \leq 1$ yields a formulation of the dual problem which has the advantage of having a nice geometric interpretation: finding the minimal distance between the convex polyhedra $\text{conv}(u_1, \dots, u_p)$ and $\text{conv}(v_1, \dots, v_q)$. Unfortunately this formulation is not useful for actually solving the problem. However, if the equivalent constraint $\|w\|^2 (= w^\top w) \leq 1$ is used, then the dual problem is much more useful as a solving tool.

In Chapter 54 we consider the case where the sets of points $\{u_1, \dots, u_p\}$ and $\{v_1, \dots, v_q\}$ are not linearly separable.

50.12 Some Techniques to Obtain a More Useful Dual Program

In some cases, it is advantageous to reformulate a primal optimization problem to obtain a more useful dual problem. Three different reformulations are proposed in Boyd and Van-

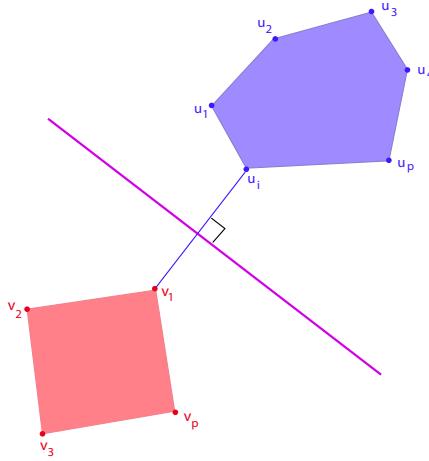

Figure 50.19: In \mathbb{R}^2 the convex hull of the u_i s, namely the blue hexagon, is separated from the convex hull of the v_j s, i.e. the red square, by the purple hyperplane (line) which is the perpendicular bisector to the blue line segment between u_i and v_1 , where this blue line segment is the shortest distance between the two convex polygons.

denberghe; see [29], Section 5.7:

- (1) Introducing new variables and associated equality constraints.
- (2) Replacing the objective function with an increasing function of the the original function.
- (3) Making explicit constraints implicit, that is, incorporating them into the domain of the objective function.

We only give illustrations of (1) and (2) and refer the reader to Boyd and Vandenberghe [29] (Section 5.7) for more examples of these techniques.

Consider the unconstrained program:

$$\text{minimize } f(Ax + b),$$

where A is an $m \times n$ matrix and $b \in \mathbb{R}^m$. While the conditions for a zero duality gap are satisfied, the Lagrangian is

$$L(x) = f(Ax + b),$$

so the dual function G is the constant function whose value is

$$G = \inf_{x \in \mathbb{R}^n} f(Ax + b),$$

which is not useful at all.

Let us reformulate the problem as

$$\begin{aligned} & \text{minimize} && f(y) \\ & \text{subject to} && Ax + b = y, \end{aligned}$$

where we introduced the new variable $y \in \mathbb{R}^m$ and the equality constraint $Ax + b = y$. The two problems are obviously equivalent. The Lagrangian of the reformulated problem is

$$L(x, y, \mu) = f(y) + \mu^\top(Ax + b - y)$$

where $\mu \in \mathbb{R}^m$. To find the dual function $G(\mu)$ we minimize $L(x, y, \mu)$ over x and y . Minimizing over x we see that $G(\mu) = -\infty$ unless $A^\top \mu = 0$, in which case we are left with

$$G(\mu) = b^\top \mu + \inf_y (f(y) - \mu^\top y) = b^\top \mu - \inf_y (\mu^\top y - f(y)) = b^\top \mu - f^*(\mu),$$

where f^* is the conjugate of f . It follows that the dual program can be expressed as

$$\begin{aligned} & \text{maximize} && b^\top \mu - f^*(\mu) \\ & \text{subject to} && A^\top \mu = 0. \end{aligned}$$

This formulation of the dual is much more useful than the dual of the original program.

Example 50.12. As a concrete example, consider the following unconstrained program:

$$\text{minimize } f(x) = \log \left(\sum_{i=1}^n e^{(A^i)^\top x + b_i} \right)$$

where A^i is a column vector in \mathbb{R}^n . We reformulate the problem by introducing new variables and equality constraints as follows:

$$\begin{aligned} & \text{minimize} && f(y) = \log \left(\sum_{i=1}^n e^{y_i} \right) \\ & \text{subject to} && Ax + b = y, \end{aligned}$$

where A is the $n \times n$ matrix whose columns are the vectors A^i and $b = (b_1, \dots, b_n)$. Since by Example 50.8(8), the conjugate of the log-sum-exp function $f(y) = \log \left(\sum_{i=1}^n e^{y_i} \right)$ is

$$f^*(\mu) = \begin{cases} \sum_{i=1}^n \mu_i \log \mu_i & \text{if } \mathbf{1}^\top \mu = 1 \text{ and } \mu \geq 0 \\ \infty & \text{otherwise,} \end{cases}$$

the dual of the reformulated problem can be expressed as

$$\text{maximize } b^\top \mu - \log\left(\sum_{i=1}^n \mu_i \log \mu_i\right)$$

subject to

$$\begin{aligned} \mathbf{1}^\top \mu &= 1 \\ A^\top \mu &= 0 \\ \mu &\geq 0, \end{aligned}$$

an entropy maximization problem.

Example 50.13. Similarly the unconstrained norm minimization problem

$$\text{minimize } \|Ax - b\|,$$

where $\|\cdot\|$ is any norm on \mathbb{R}^m , has a dual function which is a constant, and is not useful. This problem can be reformulated as

$$\begin{aligned} \text{minimize } & \|y\| \\ \text{subject to } & \end{aligned}$$

$$Ax - b = y.$$

By Example 50.8(6), the conjugate of the norm is given by

$$\|y\|^* = \begin{cases} 0 & \text{if } \|y\|^D \leq 1 \\ +\infty & \text{otherwise,} \end{cases}$$

so the dual of the reformulated program is:

$$\begin{aligned} \text{maximize } & b^\top \mu \\ \text{subject to } & \\ & \|\mu\|^D \leq 1 \\ & A^\top \mu = 0. \end{aligned}$$

Here is now an example of (2), replacing the objective function with an increasing function of the the original function.

Example 50.14. The norm minimization of Example 50.13 can be reformulated as

$$\begin{aligned} \text{minimize } & \frac{1}{2} \|y\|^2 \\ \text{subject to } & \\ & Ax - b = y. \end{aligned}$$

This program is obviously equivalent to the original one. By Example 50.8(7), the conjugate of the square norm is given by

$$\frac{1}{2}(\|y\|^D)^2,$$

so the dual of the reformulated program is

$$\begin{aligned} & \text{maximize} && -\frac{1}{2}(\|\mu\|^D)^2 + b^\top \mu \\ & \text{subject to} && A^\top \mu = 0. \end{aligned}$$

Note that this dual is different from the dual obtained in Example 50.13.

The objective function of the dual program in Example 50.13 is linear, but we have the nonlinear constraint $\|\mu\|^D \leq 1$. On the other hand, the objective function of the dual program of Example 50.14 is quadratic, whereas its constraints are affine. We have other examples of this trade-off with the Programs (SVM_{*h2*}) (quadratic objective function, affine constraints), and (SVM_{*h1*}) (linear objective function, one nonlinear constraint).

Sometimes, it is also helpful to replace a constraint by an increasing function of this constraint; for example, to use the constraint $\|w\|_2^2 (= w^\top w) \leq 1$ instead of $\|w\|_2 \leq 1$.

In Chapter 55 we revisit the problem of solving an overdetermined or underdetermined linear system $Ax = b$ considered in Section 23.1, from a different point of view.

50.13 Uzawa's Method

Let us go back to our Minimization Problem

$$\begin{aligned} & \text{minimize} && J(v) \\ & \text{subject to} && \varphi_i(v) \leq 0, \quad i = 1, \dots, m, \end{aligned}$$

where the functions J and φ_i are defined on some open subset Ω of a finite-dimensional Euclidean vector space V (more generally, a real Hilbert space V). As usual, let

$$U = \{v \in V \mid \varphi_i(v) \leq 0, 1 \leq i \leq m\}.$$

If the functional J satisfies the inequalities of Proposition 49.18 and if the functions φ_i are convex, in theory, the projected-gradient method converges to the unique minimizer of J over U . Unfortunately, it is usually impossible to compute the projection map $p_U: V \rightarrow U$.

On the other hand, the domain of the Lagrange dual function $G: \mathbb{R}_+^m \rightarrow \mathbb{R}$ given by

$$G(\mu) = \inf_{v \in \Omega} L(v, \mu) \quad \mu \in \mathbb{R}_+^m,$$

is \mathbb{R}_+^m , where

$$L(v, \mu) = J(v) + \sum_{i=1}^m \mu_i \varphi_i(v)$$

is the Lagrangian of our problem. Now the projection p_+ from \mathbb{R}^m to \mathbb{R}_+^m is very simple, namely

$$(p_+(\lambda))_i = \max\{\lambda_i, 0\}, \quad 1 \leq i \leq m.$$

It follows that the projection-gradient method should be applicable to the *Dual Problem (D)*:

$$\begin{aligned} & \text{maximize } G(\mu) \\ & \text{subject to } \mu \in \mathbb{R}_+^m. \end{aligned}$$

If the hypotheses of Theorem 50.17 hold, then a solution λ of the Dual Program (D) yields a solution u_λ of the primal problem.

Uzawa's method is essentially the gradient method with fixed stepsize applied to the Dual Problem (D). However, it is designed to yield a solution of the primal problem.

Uzawa's method:

Given an arbitrary initial vector $\lambda^0 \in \mathbb{R}_+^m$, two sequences $(\lambda^k)_{k \geq 0}$ and $(u^k)_{k \geq 0}$ are constructed, with $\lambda^k \in \mathbb{R}_+^m$ and $u^k \in V$.

Assuming that $\lambda^0, \lambda^1, \dots, \lambda^k$ are known, u^k and λ^{k+1} are determined as follows:

u^k is the unique solution of the minimization problem, find $u^k \in V$ such that

$$(UZ) \quad \begin{cases} J(u^k) + \sum_{i=1}^m \lambda_i^k \varphi_i(u^k) = \inf_{v \in V} \left(J(v) + \sum_{i=1}^m \lambda_i^k \varphi_i(v) \right); \text{ and} \\ \lambda_i^{k+1} = \max\{\lambda_i^k + \rho \varphi_i(u^k), 0\}, \quad 1 \leq i \leq m, \end{cases}$$

where $\rho > 0$ is a suitably chosen parameter.

Recall that in the proof of Theorem 50.17 we showed $(*)_{\text{deriv}}$, namely

$$G'_{\lambda^k}(\xi) = \langle \nabla G_{\lambda^k}, \xi \rangle = \sum_{i=1}^m \xi_i \varphi_i(u^k),$$

which means that $(\nabla G_{\lambda^k})_i = \varphi_i(u^k)$. Then the second equation in (UZ) corresponds to the gradient-projection step

$$\lambda^{k+1} = p_+(\lambda^k + \rho \nabla G_{\lambda^k}).$$

Note that because the problem is a maximization problem we use a positive sign instead of a negative sign. Uzawa's method is indeed a gradient method.

Basically, Uzawa's method replaces a constrained optimization problem by a sequence of unconstrained optimization problems involving the Lagrangian of the (primal) problem.

Interestingly, under certain hypotheses, it is possible to prove that the sequence of approximate solutions $(u^k)_{k \geq 0}$ converges to the minimizer u of J over U , even if the sequence $(\lambda^k)_{k \geq 0}$ does not converge. We prove such a result when the constraints φ_i are *affine*.

Theorem 50.21. *Suppose $J: \mathbb{R}^n \rightarrow \mathbb{R}$ is an elliptic functional, which means that J is continuously differentiable on \mathbb{R}^n , and there is some constant $\alpha > 0$ such that*

$$\langle \nabla J_v - \nabla J_u, v - u \rangle \geq \alpha \|v - u\|^2 \quad \text{for all } u, v \in \mathbb{R}^n,$$

and that U is a nonempty closed convex subset given by

$$U = \{v \in \mathbb{R}^n \mid Cv \leq d\},$$

where C is a real $m \times n$ matrix and $d \in \mathbb{R}^m$. If the scalar ρ satisfies the condition

$$0 < \rho < \frac{2\alpha}{\|C\|_2^2},$$

where $\|C\|_2$ is the spectral norm of C , then the sequence $(u^k)_{k \geq 0}$ computed by Uzawa's method converges to the unique minimizer $u \in U$ of J .

Furthermore, if C has rank m , then the sequence $(\lambda^k)_{k \geq 0}$ converges to the unique maximizer of the Dual Problem (D) .

Proof.

Step 1. We establish algebraic conditions relating the unique minimizer $u \in U$ of J over U and some $\lambda \in \mathbb{R}_+^m$ such that (u, λ) is a saddle point.

Since J is elliptic and U is nonempty closed and convex, by Theorem 49.8, the functional J is strictly convex, so it has a unique minimizer $u \in U$. Since J is convex and the constraints are affine, by Theorem 50.17(2) the Dual Problem (D) has at least one solution. By Theorem 50.15(2), there is some $\lambda \in \mathbb{R}_+^m$ such that (u, λ) is a saddle point of the Lagrangian L .

If we define the affine function φ by

$$\varphi(v) = (\varphi_1(v), \dots, \varphi_m(v)) = Cv - d,$$

then the Lagrangian $L(v, \mu)$ can be written as

$$L(v, \mu) = J(v) + \sum_{i=1}^m \mu_i \varphi_i(v) = J(v) + \langle C^\top \mu, v \rangle - \langle \mu, d \rangle.$$

Since

$$L(u, \lambda) = \inf_{v \in \mathbb{R}^n} L(v, \lambda),$$

by Theorem 40.13(4) we must have

$$\nabla J_u + C^\top \lambda = 0, \tag{*1}$$

and since

$$G(\lambda) = L(u, \lambda) = \sup_{\mu \in \mathbb{R}_+^m} L(u, \mu),$$

by Theorem 40.13(3) (and since maximizing a function g is equivalent to minimizing $-g$), we must have

$$G'_\lambda(\mu - \lambda) \leq 0 \quad \text{for all } \mu \in \mathbb{R}_+^m,$$

and since as noted earlier $\nabla G_\lambda = \varphi(u)$, we get

$$\langle \varphi(u), \mu - \lambda \rangle \leq 0 \quad \text{for all } \mu \in \mathbb{R}_+^m. \quad (*_2)$$

As in the proof of Proposition 49.18, $(*_2)$ can be expressed as follows for every $\rho > 0$:

$$\langle \lambda - (\lambda + \rho \varphi(u)), \mu - \lambda \rangle \geq 0 \quad \text{for all } \mu \in \mathbb{R}_+^m, \quad (**_2)$$

which shows that λ can be viewed as the projection onto \mathbb{R}_+^m of the vector $\lambda + \rho \varphi(u)$. In summary we obtain the equations

$$(\dagger_1) \quad \begin{cases} \nabla J_u + C^\top \lambda = 0 \\ \lambda = p_+(\lambda + \rho \varphi(u)). \end{cases}$$

Step 2. We establish algebraic conditions relating the unique solution u_k of the minimization problem arising during an iteration of Uzawa's method in (UZ) and λ^k .

Observe that the Lagrangian $L(v, \mu)$ is strictly convex as a function of v (as the sum of a strictly convex function and an affine function). As in the proof of Theorem 49.8(1) and using Cauchy–Schwarz, we have

$$\begin{aligned} J(v) + \langle C^\top \mu, v \rangle &\geq J(0) + \langle \nabla J_0, v \rangle + \frac{\alpha}{2} \|v\|^2 + \langle C^\top \mu, v \rangle \\ &\geq J(0) - \|\nabla J_0\| \|v\| - \|C^\top \mu\| \|v\| + \frac{\alpha}{2} \|v\|^2, \end{aligned}$$

and the term $(-\|\nabla J_0\| - \|C^\top \mu\| \|v\| + \frac{\alpha}{2} \|v\|) \|v\|$ goes to $+\infty$ when $\|v\|$ tends to $+\infty$, so $L(v, \mu)$ is coercive as a function of v . Therefore, the minimization problem find u^k such that

$$J(u^k) + \sum_{i=1}^m \lambda_i^k \varphi_i(u^k) = \inf_{v \in \mathbb{R}^n} \left(J(v) + \sum_{i=1}^m \lambda_i^k \varphi_i(v) \right)$$

has a unique solution $u^k \in \mathbb{R}^n$. It follows from Theorem 40.13(4) that the vector u^k must satisfy the equation

$$\nabla J_{u^k} + C^\top \lambda^k = 0, \quad (*_3)$$

and since by definition of Uzawa's method

$$\lambda^{k+1} = p_+(\lambda^k + \rho \varphi(u^k)), \quad (*_4)$$

we obtain the equations

$$(\dagger_2) \quad \begin{cases} \nabla J_{u^k} + C^\top \lambda^k = 0 \\ \lambda^{k+1} = p_+(\lambda^k + \rho \varphi(u^k)). \end{cases}$$

Step 3. By subtracting the first of the two equations of (\dagger_1) and (\dagger_2) we obtain

$$\nabla J_{u^k} - \nabla J_u + C^\top (\lambda^k - \lambda) = 0,$$

and by subtracting the second of the two equations of (\dagger_1) and (\dagger_2) and using Proposition 48.6, we obtain

$$\|\lambda^{k+1} - \lambda\| \leq \|\lambda^k - \lambda + \rho C(u^k - u)\|.$$

In summary, we proved

$$(\dagger) \quad \begin{cases} \nabla J_{u^k} - \nabla J_u + C^\top (\lambda^k - \lambda) = 0 \\ \|\lambda^{k+1} - \lambda\| \leq \|\lambda^k - \lambda + \rho C(u^k - u)\|. \end{cases}$$

Step 4. Convergence of the sequence $(u^k)_{k \geq 0}$ to u .

Squaring both sides of the inequality in (\dagger) we obtain

$$\|\lambda^{k+1} - \lambda\|^2 \leq \|\lambda^k - \lambda\|^2 + 2\rho \langle C^\top (\lambda^k - \lambda), u_k - u \rangle + \rho^2 \|C(u^k - u)\|^2.$$

Using the equation in (\dagger) and the inequality

$$\langle \nabla J_{u^k} - \nabla J_u, u^k - u \rangle \geq \alpha \|u^k - u\|^2,$$

we get

$$\begin{aligned} \|\lambda^{k+1} - \lambda\|^2 &\leq \|\lambda^k - \lambda\|^2 - 2\rho \langle \nabla J_{u^k} - \nabla J_u, u^k - u \rangle + \rho^2 \|C(u^k - u)\|^2 \\ &\leq \|\lambda^k - \lambda\|^2 - \rho(2\alpha - \rho \|C\|_2^2) \|u^k - u\|^2. \end{aligned}$$

Consequently, if

$$0 \leq \rho \leq \frac{2\alpha}{\|C\|_2^2},$$

we have

$$\|\lambda^{k+1} - \lambda\| \leq \|\lambda^k - \lambda\|, \quad \text{for all } k \geq 0. \quad (*_5)$$

By $(*_5)$, the sequence $(\|\lambda^k - \lambda\|)_{k \geq 0}$ is nonincreasing and bounded below by 0, so it converges, which implies that

$$\lim_{k \rightarrow \infty} (\|\lambda^{k+1} - \lambda\| - \|\lambda^k - \lambda\|) = 0,$$

and since

$$\|\lambda^{k+1} - \lambda\|^2 \leq \|\lambda^k - \lambda\|^2 - \rho(2\alpha - \rho \|C\|_2^2) \|u^k - u\|^2,$$

we also have

$$\rho(2\alpha - \rho \|C\|_2^2) \|u^k - u\|^2 \leq \|\lambda^k - \lambda\|^2 - \|\lambda^{k+1} - \lambda\|^2.$$

So if

$$0 < \rho < \frac{2\alpha}{\|C\|_2^2},$$

then $\rho(2\alpha - \rho \|C\|_2^2) > 0$, and we conclude that

$$\lim_{k \rightarrow \infty} \|u^k - u\| = 0,$$

that is, the sequence $(u^k)_{k \geq 0}$ converges to u .

Step 5. Convergence of the sequence $(\lambda^k)_{k \geq 0}$ to λ if C has rank m .

Since the sequence $(\|\lambda^k - \lambda\|)_{k \geq 0}$ is nonincreasing, the sequence $(\lambda^k)_{k \geq 0}$ is bounded, and thus it has a convergent subsequence $(\lambda^{i(k)})_{i \geq 0}$ whose limit is some $\lambda' \in \mathbb{R}_+^m$. Since J' is continuous, by (\dagger_2) we have

$$\nabla J_u + C^\top \lambda' = \lim_{i \rightarrow \infty} (\nabla J_{u^{i(k)}} + C^\top \lambda^{i(k)}) = 0. \quad (*_6)$$

If C has rank m , then $\text{Im}(C) = \mathbb{R}^m$, which is equivalent to $\text{Ker}(C^\top) = \{0\}$, so C^\top is injective and since by (\dagger_1) we also have $\nabla J_u + C^\top \lambda = 0$, we conclude that $\lambda' = \lambda$. The above reasoning applies to any subsequence of $(\lambda^k)_{k \geq 0}$, so $(\lambda^k)_{k \geq 0}$ converges to λ . \square

In the special case where J is an elliptic quadratic functional

$$J(v) = \frac{1}{2} \langle Av, v \rangle - \langle b, v \rangle,$$

where A is symmetric positive definite, by (\dagger_2) an iteration of Uzawa's method gives

$$\begin{aligned} Au^k - b + C^\top \lambda^k &= 0 \\ \lambda_i^{k+1} &= \max\{(\lambda^k + \rho(Cu^k - d))_i, 0\}, \quad 1 \leq i \leq m. \end{aligned}$$

Theorem 50.21 implies that Uzawa's method converges if

$$0 < \rho < \frac{2\lambda_1}{\|C\|_2^2},$$

where λ_1 is the smallest eigenvalue of A .

If we solve for u^k using the first equation, we get

$$\lambda^{k+1} = p_+(\lambda^k + \rho(-CA^{-1}C^\top \lambda^k + CA^{-1}b - d)). \quad (*_7)$$

In Example 50.7 we showed that the gradient of the dual function G is given by

$$\nabla G_\mu = Cu_\mu - d = -CA^{-1}C^\top \mu + CA^{-1}b - d,$$

so $(*_7)$ can be written as

$$\lambda^{k+1} = p_+(\lambda^k + \rho \nabla G_{\lambda^k});$$

this shows that Uzawa's method is indeed the gradient method with fixed stepsize applied to the dual program.

50.14 Summary

The main concepts and results of this chapter are listed below:

- The cone of feasible directions.
- Cone with apex.
- Active and inactive constraints.
- Qualified constraint at u .
- Farkas lemma.
- Farkas–Minkowski lemma.
- Karush–Kuhn–Tucker optimality conditions (or *KKT*-conditions).
- Complementary slackness conditions.
- Generalized Lagrange multipliers.
- Qualified convex constraint.
- Lagrangian of a minimization problem.
- Equality constrained minimization.
- KKT matrix.
- Newton’s method with equality constraints (feasible start and infeasible start).
- Hard margin support vector machine
- Training data
- Linearly separable sets of points.
- Maximal margin hyperplane.
- Support vectors
- Saddle points.
- Lagrange dual function.
- Lagrange dual program.
- Duality gap.

- Weak duality.
- Strong duality.
- Handling equality constraints in the Lagrangian.
- Dual of the Hard Margin SVM (SVM_{h2}).
- Conjugate functions and Legendre dual functions.
- Dual of the Hard Margin SVM (SVM_{h1}).
- Uzawa's Method.

50.15 Problems

Problem 50.1. Prove (3) and (4) of Proposition 50.11.

Problem 50.2. Assume that in Theorem 50.17, $V = \mathbb{R}^n$, J is elliptic and the constraints φ_i are of the form

$$\sum_{j=1}^n c_{ij} v_j \leq d_i,$$

that is, affine. Prove that the Problem (P_μ) has a unique solution which is continuous in μ .

Problem 50.3. (1) Prove that the set of saddle points of a function $L: \Omega \times M \rightarrow \mathbb{R}$ is of the form $V_0 \times M_0$, for some $V_0 \subseteq \Omega$ and some $M_0 \subseteq M$.

(2) Assume that Ω and M are convex subsets of some normed vector spaces, assume that for any fixed $v \in \Omega$ the map

$$\mu \mapsto L(v, \mu) \quad \text{is concave,}$$

and for any fixed $\mu \in M$ the map

$$v \mapsto L(v, \mu) \quad \text{is convex.}$$

Prove that $V_0 \times M_0$ is convex.

(3) Prove that if for every fixed $\mu \in M$ the map

$$v \mapsto L(v, \mu) \quad \text{is strictly convex,}$$

then V_0 has at most one element.

Problem 50.4. Prove that the conjugate of the function f given by $f(X) = \log \det(X^{-1})$, where X is an $n \times n$ symmetric positive definite matrix, is

$$f^*(Y) = \log \det((-Y)^{-1}) - n,$$

where Y is an $n \times n$ symmetric negative definite matrix.

Problem 50.5. (From Boyd and Vandenberghe [29], Problem 5.12) Given an $m \times n$ matrix A and any vector $b \in \mathbb{R}^m$, consider the problem

$$\begin{aligned} & \text{minimize} && -\sum_{i=1}^m \log(b_i - a_i x) \\ & \text{subject to} && Ax < b, \end{aligned}$$

where a_i is the i th row of A . This is called the *analytic centering problem*. It can be shown that the problem has a unique solution iff the open polyhedron $\{x \in \mathbb{R}^n \mid Ax < b\}$ is nonempty and bounded.

(1) Prove that necessary and sufficient conditions for the problem to have an optimal solution are

$$Ax < b, \quad \sum_{i=1}^m \frac{a_i^\top}{b_i - a_i x} = 0.$$

(2) Derive a dual program for the above program.

Hint. First introduce new variables y_i and equations $y_i = b_i - a_i x$.

Problem 50.6. (From Boyd and Vandenberghe [29], Problem 5.13) A *Boolean linear program* is the following optimization problem:

$$\begin{aligned} & \text{minimize} && c^\top x \\ & \text{subject to} && Ax \leq b \\ & && x_i \in \{0, 1\}, i = 1, \dots, n, \end{aligned}$$

where A is an $m \times n$ matrix, $c \in \mathbb{R}^n$ and $b \in \mathbb{R}^m$. The fact that the solutions $x \in \mathbb{R}^n$ are constrained to have coordinates x_i taking the values 0 or 1 makes it a hard problem. The above problem can be stated as a program with quadratic constraints:

$$\begin{aligned} & \text{minimize} && c^\top x \\ & \text{subject to} && Ax \leq b \\ & && x_i(1 - x_i) = 0, i = 1, \dots, n. \end{aligned}$$

(1) Derive the Lagrangian dual of the above program.

(2) A way to approximate a solution of the Boolean linear program is to consider its linear relaxation where the constraints $x_i \in \{0, 1\}$ are replaced by the *linear constraints* $0 \leq x_i \leq 1$:

$$\begin{aligned} & \text{minimize} && c^\top x \\ & \text{subject to} && Ax \leq b \\ & && 0 \leq x_i \leq 1, i = 1, \dots, n. \end{aligned}$$

Find the dual linear program of the above linear program. Show that the maxima of the dual programs in (1) and (2) are the same.

Chapter 51

Subgradients and Subdifferentials of Convex Functions \circledast

In this chapter we consider some deeper aspects of the theory of convex functions that are not necessarily differentiable at every point of their domain. Some substitute for the gradient is needed. Fortunately, for convex functions, there is such a notion, namely subgradients. Geometrically, given a (proper) convex function f , the subgradients at x are vectors normal to supporting hyperplanes to the epigraph of the function at $(x, f(x))$. The subdifferential $\partial f(x)$ to f at x is the set of all subgradients at x . A crucial property is that f is differentiable at x iff $\partial f(x) = \{\nabla f_x\}$, where ∇f_x is the gradient of f at x . Another important property is that a (proper) convex function f attains its minimum at x iff $0 \in \partial f(x)$. A major motivation for developing this more sophisticated theory of “differentiation” of convex functions is to extend the Lagrangian framework to convex functions that are not necessarily differentiable.

Experience shows that the applicability of convex optimization is significantly increased by considering extended real-valued functions, namely functions $f: S \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$, where S is some subset of \mathbb{R}^n (usually convex). This is reminiscent of what happens in measure theory, where it is natural to consider functions that take the value $+\infty$. We already encountered functions that take the value $-\infty$ as a result of a minimization that does not converge. For example, if $J(u, v) = u$, and we have the affine constraint $v = 0$, for any fixed λ , the minimization problem

$$\begin{aligned} & \text{minimize} && u + \lambda v \\ & \text{subject to} && v = 0, \end{aligned}$$

yields the solution $u = -\infty$ and $v = 0$.

Until now, we chose not to consider functions taking the value $-\infty$, and instead we considered partial functions, but it turns out to be convenient to admit functions taking the value $-\infty$.

Allowing functions to take the value $+\infty$ is also a convenient alternative to dealing with partial functions. This situation is well illustrated by the indicator function of a convex set.

Definition 51.1. Let $C \subseteq \mathbb{R}^n$ be any subset of \mathbb{R}^n . The *indicator function* I_C of C is the function given by

$$I_C(u) = \begin{cases} 0 & \text{if } u \in C \\ +\infty & \text{if } u \notin C. \end{cases}$$

The indicator function I_C is a variant of the characteristic function χ_C of the set C (defined such that $\chi_C(u) = 1$ if $u \in C$ and $\chi_C(u) = 0$ if $u \notin C$). Rockafellar denotes the indicator function I_C by $\delta(-|C)$; that is, $\delta(u|C) = I_C(u)$; see Rockafellar [138], Page 28.

Given a partial function $f: \mathbb{R}^n \rightarrow \mathbb{R} \cup \{-\infty\}$, by setting $f(u) = +\infty$ if $u \notin \text{dom}(f)$, we convert the partial function f into a total function with values in $\mathbb{R} \cup \{-\infty, +\infty\}$. Still, one has to remember that such functions are really partial functions, but $-\infty$ and $+\infty$ play different roles. The value $f(x) = -\infty$ indicates that computing $f(x)$ using a *minimization procedure did not terminate*, but $f(x) = +\infty$ means that the *function f is really undefined at x*.

The definition of a convex function $f: S \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$ needs to be slightly modified to accommodate the infinite values $\pm\infty$. The cleanest definition uses the notion of epigraph.

A remarkable and very useful fact is that the optimization problem

$$\begin{aligned} & \text{minimize} && J(u) \\ & \text{subject to} && u \in C, \end{aligned}$$

where C is a closed convex set in \mathbb{R}^n and J is a convex function can be rewritten in term of the indicator function I_C of C , as

$$\begin{aligned} & \text{minimize} && J(u) + I_C(z) \\ & \text{subject to} && u - z = 0. \end{aligned}$$

But $J(u) + I_C(z)$ is not differentiable, even if J is, which forces us to deal with convex functions which are not differentiable

Convex functions are not necessarily differentiable, but if a convex function f has a finite value $f(u)$ at u (which means that $f(u) \in \mathbb{R}$), then it has a one-sided directional derivative at u . Another crucial notion is the notion of subgradient, which is a substitute for the notion of gradient when the function f is not differentiable at u .

In Section 51.1, we introduce extended real-valued functions, which are functions that may also take the values $\pm\infty$. In particular, we define proper convex functions, and the closure of a convex function. Subgradients and subdifferentials are defined in Section 51.2. We discuss some properties of subgradients in Section 51.3 and Section 51.4. In particular, we relate subgradients to one-sided directional derivatives. In Section 51.5, we discuss the problem of finding the minimum of a proper convex function and give some criteria in terms of subdifferentials. In Section 51.6, we sketch the generalization of the results presented in Chapter 50 about the Lagrangian framework to programs allowing an objective function and

inequality constraints which are convex but not necessarily differentiable. In fact, it is fair to say that the theory of extended real-valued convex functions and the notions of subgradient and subdifferential developed in this chapter constitute the machinery needed to extend the Lagrangian framework to convex functions that are not necessarily differentiable.

This chapter relies heavily on Rockafellar [138]. Some of the results in this chapter are also discussed in Bertsekas [16, 19, 17]. It should be noted that Bertsekas has developed a framework to discuss duality that he refers to as the *min common/max crossing* framework, for short MC/MC. Although this framework is elegant and interesting in its own right, the fact that Bertsekas relies on it to prove properties of subdifferentials makes it little harder for a reader to “jump in.”

51.1 Extended Real-Valued Convex Functions

We extend the ordering on \mathbb{R} by setting

$$-\infty < x < +\infty, \quad \text{for all } x \in \mathbb{R}.$$

Definition 51.2. A (total) function $f: \mathbb{R}^n \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$ is called an *extended real-valued function*. For any $x \in \mathbb{R}^n$, we say that $f(x)$ is *finite* if $f(x) \in \mathbb{R}$ (equivalently, $f(x) \neq \pm\infty$). The function f is *finite* if $f(x)$ is finite for all $x \in \mathbb{R}^n$.

Adapting slightly Definition 40.8, given a function $f: \mathbb{R}^n \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$, the *epigraph* of f is the subset of \mathbb{R}^{n+1} given by

$$\mathbf{epi}(f) = \{(x, y) \in \mathbb{R}^{n+1} \mid f(x) \leq y\}.$$

See Figure 51.1.

If S is a nonempty subset of \mathbb{R}^n , the epigraph of the restriction of f to S is defined as

$$\mathbf{epi}(f|S) = \{(x, y) \in \mathbb{R}^{n+1} \mid f(x) \leq y, x \in S\}.$$

Observe the following facts:

1. For any $x \in S$, if $f(x) = -\infty$, then $\mathbf{epi}(f)$ contains the “vertical line” $\{(x, y) \mid y \in \mathbb{R}\}$ in \mathbb{R}^{n+1} .
2. For any $x \in S$, if $f(x) \in \mathbb{R}$, then $\mathbf{epi}(f)$ contains the ray $\{(x, y) \mid f(x) \leq y\}$ in \mathbb{R}^{n+1} .
3. For any $x \in S$, if $f(x) = +\infty$, then $\mathbf{epi}(f)$ does not contain any point (x, y) , with $y \in \mathbb{R}$.
4. We have $\mathbf{epi}(f) = \emptyset$ iff f corresponds to the partial function undefined everywhere; that is, $f(x) = +\infty$ for all $x \in \mathbb{R}^n$.

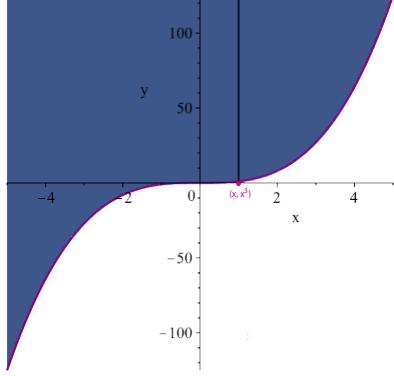

Figure 51.1: Let $f: \mathbb{R} \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$ be given by $f(x) = x^3$ for $x \in \mathbb{R}$. Its graph in \mathbb{R}^2 is the magenta curve, and its epigraph is the union of the magenta curve and blue region “above” this curve. For any point $x \in \mathbb{R}$, $\text{epi}(f)$ contains the ray which starts at (x, x^3) and extends upward.

Definition 51.3. Given a nonempty subset S of \mathbb{R}^n , a (total) function $f: \mathbb{R}^n \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$ is *convex* on S if its epigraph $\text{epi}(f|S)$ is convex as a subset of \mathbb{R}^{n+1} . See Figure 51.2. The function f is *concave* on S if $-f$ is convex on S . The function f is *affine* on S if it is finite, convex, and concave. If $S = \mathbb{R}^n$, we simply that f is *convex* (resp. *concave*, resp. *affine*).

Definition 51.4. Given any function $f: \mathbb{R}^n \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$, the *effective domain* $\text{dom}(f)$ of f is given by

$$\text{dom}(f) = \{x \in \mathbb{R}^n \mid (\exists y \in \mathbb{R})((x, y) \in \text{epi}(f))\} = \{x \in \mathbb{R}^n \mid f(x) < +\infty\}.$$

Observe that the effective domain of f contains the vectors $x \in \mathbb{R}^n$ such that $f(x) = -\infty$, but excludes the vectors $x \in \mathbb{R}^n$ such that $f(x) = +\infty$.

Example 51.1. The above fact is illustrated by the function $f: \mathbb{R} \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$ where

$$f(x) = \begin{cases} -x^2 & \text{if } x \geq 0 \\ +\infty & \text{if } x < 0. \end{cases}$$

The epigraph of this function is illustrated Figure 51.3. By definition $\text{dom}(f) = [0, \infty)$.

If f is a convex function, since $\text{dom}(f)$ is the image of $\text{epi}(f)$ by a linear map (a projection), *it is convex*.

By definition, $\text{epi}(f|S)$ is convex iff for any (x_1, y_1) and (x_2, y_2) with $x_1, x_2 \in S$ and $y_1, y_2 \in \mathbb{R}$ such that $f(x_1) \leq y_1$ and $f(x_2) \leq y_2$, for every λ such that $0 \leq \lambda \leq 1$, we have

$$(1 - \lambda)(x_1, y_1) + \lambda(x_2, y_2) = ((1 - \lambda)x_1 + \lambda x_2, (1 - \lambda)y_1 + \lambda y_2) \in \text{epi}(f|S),$$

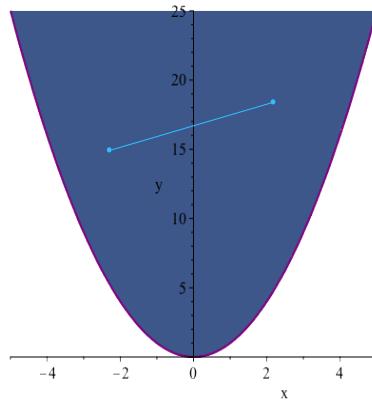

Figure 51.2: Let $f: \mathbb{R} \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$ be given by $f(x) = x^2$ for $x \in \mathbb{R}$. Its graph in \mathbb{R}^2 is the magenta curve, and its epigraph is the union of the magenta curve and blue region “above” this curve. Observe that $\text{epi}(f)$ is a convex set of \mathbb{R}^2 since the aqua line segment connecting any two points is contained within the epigraph.

which means that $(1 - \lambda)x_1 + \lambda x_2 \in S$ and

$$f((1 - \lambda)x_1 + \lambda x_2) \leq (1 - \lambda)y_1 + \lambda y_2. \quad (*)$$

Thus S must be convex and $f((1 - \lambda)x_1 + \lambda x_2) < +\infty$. Condition $(*)$ is a little awkward, since it does not refer explicitly to $f(x_1)$ and $f(x_2)$, as these values may be $-\infty$, in which case it is not clear what the expression $(1 - \lambda)f(x_1) + \lambda f(x_2)$ means.

In order to perform arithmetic operations involving $-\infty$ and $+\infty$, we adopt the following conventions:

$\alpha + (+\infty) = +\infty + \alpha = +\infty$	$-\infty < \alpha \leq +\infty$
$\alpha + -\infty = -\infty + \alpha = -\infty$	$-\infty \leq \alpha < +\infty$
$\alpha(+\infty) = (+\infty)\alpha = +\infty$	$0 < \alpha \leq +\infty$
$\alpha(-\infty) = (-\infty)\alpha = -\infty$	$0 < \alpha \leq +\infty$
$\alpha(+\infty) = (+\infty)\alpha = -\infty$	$-\infty \leq \alpha \leq 0$
$\alpha(-\infty) = (-\infty)\alpha = +\infty$	$-\infty \leq \alpha < 0$
$0(+\infty) = (+\infty)0 = 0$	$0(-\infty) = (-\infty)0 = 0$
$-(-\infty) = +\infty$	
$\inf \emptyset = +\infty$	$\sup \emptyset = -\infty$.

The expressions $+\infty + (-\infty)$ and $-\infty + (+\infty)$ are *meaningless*.

The following characterizations of convex functions are easy to show.

Proposition 51.1. *Let C be a nonempty convex subset of \mathbb{R}^n .*

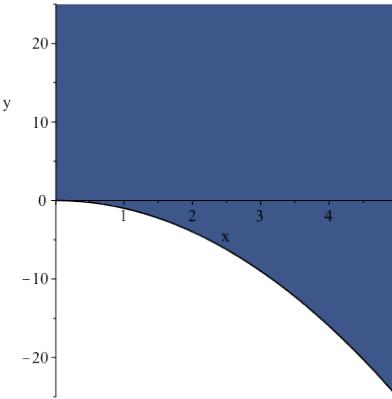

Figure 51.3: The epigraph of the concave function $f(x) = -x^2$ if $x \geq 0$ and $+\infty$ otherwise.

(1) A function $f: C \rightarrow \mathbb{R}^n \cup \{+\infty\}$ is convex on C iff

$$f((1-\lambda)x + \lambda y) \leq (1-\lambda)f(x) + \lambda f(y)$$

for all $x, y \in C$ and all λ such that $0 < \lambda < 1$.

(2) A function $f: \mathbb{R}^n \rightarrow \mathbb{R}^n \cup \{-\infty, +\infty\}$ is convex iff

$$f((1-\lambda)x + \lambda y) < (1-\lambda)\alpha + \lambda\beta$$

for all $\alpha, \beta \in \mathbb{R}$, all $x, y \in \mathbb{R}^n$ such that $f(x) < \alpha$ and $f(y) < \beta$, and all λ such that $0 < \lambda < 1$.

The “good” convex functions that we would like to deal with are defined below.

Definition 51.5. A convex function $f: \mathbb{R}^n \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$ is *proper*¹ if its epigraph is nonempty and does not contain any vertical line. Equivalently, a convex function f is proper if $f(x) > -\infty$ for all $x \in \mathbb{R}^n$ and $f(x) < +\infty$ for some $x \in \mathbb{R}^n$. A convex function which is not proper is called an *improper function*.

Observe that a convex function f is proper iff $\text{dom}(f) \neq \emptyset$ and if the restriction of f to $\text{dom}(f)$ is a finite function.

It is immediately verified that a set C is convex iff its indicator function I_C is convex, and clearly, the indicator function of a convex set is proper.

The important object of study is the set of proper functions, but improper functions can't be avoided.

¹This terminology is unfortunate because it clashes with the notion of a proper function from topology, which has to do with the preservation of compact subsets under inverse images.

Example 51.2. Here is an example of an improper convex function $f: \mathbb{R} \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$:

$$f(x) = \begin{cases} -\infty & \text{if } |x| < 1 \\ 0 & \text{if } |x| = 1 \\ +\infty & \text{if } |x| > 1 \end{cases}$$

Observe that $\text{dom}(f) = [-1, 1]$, and that $\text{epi}(f)$ is not closed. See Figure 51.4.

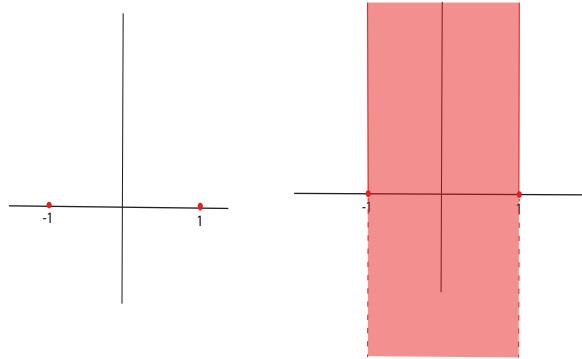

Figure 51.4: The improper convex function of Example 51.2 and its epigraph depicted as a rose colored region of \mathbb{R}^2 .

Functions whose epigraph are closed tend to have better properties. To characterize such functions we introduce sublevel sets.

Definition 51.6. Given a function $f: \mathbb{R}^n \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$, for any $\alpha \in \mathbb{R} \cup \{-\infty, +\infty\}$, the *sublevel sets* $\text{sublev}_\alpha(f)$ and $\text{sublev}_{<\alpha}(f)$ are the sets

$$\text{sublev}_\alpha(f) = \{x \in \mathbb{R}^n \mid f(x) \leq \alpha\} \quad \text{and} \quad \text{sublev}_{<\alpha}(f) = \{x \in \mathbb{R}^n \mid f(x) < \alpha\}.$$

For the improper convex function of Example 51.2, we have

$$\text{sublev}_{-\infty}(f) = (-1, 1) \text{ while } \text{sublev}_{<-\infty}(f) = \emptyset.$$

$$\text{sublev}_\alpha(f) = (-1, 1) = \text{sublev}_{<\alpha}(f) \text{ whenever } -\infty < \alpha < 0.$$

$$\text{sublev}_0(f) = [-1, 1] \text{ while } \text{sublev}_{<0}(f) = (-1, 1).$$

$$\text{sublev}_\alpha(f) = [-1, 1] = \text{sublev}_{<\alpha}(f) \text{ whenever } 0 < \alpha < +\infty.$$

$$\text{sublev}_{+\infty}(f) = \mathbb{R} \text{ while } \text{sublev}_{<+\infty}(f) = [-1, 1].$$

A useful corollary of Proposition 51.1 is the following result whose (easy) proof can be found in Rockafellar [138] (Theorem 4.6).

Proposition 51.2. *If f is any convex function on \mathbb{R}^n , then for every $\alpha \in \mathbb{R} \cup \{-\infty, +\infty\}$, the sublevel sets $\text{sublev}_\alpha(f)$ and $\text{sublev}_{<\alpha}(f)$ are convex.*

Definition 51.7. A function $f: \mathbb{R}^n \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$ is *lower semi-continuous* if the sublevel sets $\text{sublev}_\alpha(f) = \{x \in \mathbb{R}^n \mid f(x) \leq \alpha\}$ are closed for all $\alpha \in \mathbb{R}$.

Observe that the improper convex function of Example 51.2 is not lower semi-continuous since $\text{sublev}_\alpha(f) = (-1, 1)$ whenever $-\infty < \alpha < 0$. This result reflects the fact that epigraph is not closed as shown in the following proposition; see Rockafellar [138] (Theorem 7.1).

Proposition 51.3. *Let $f: \mathbb{R}^n \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$ be any function. The following properties are equivalent:*

- (1) *The function f is lower semi-continuous.*
- (2) *The epigraph of f is a closed set in \mathbb{R}^{n+1} .*

The notion of the closure of convex function plays an important role. It is a bit subtle because a convex function may be improper.

Definition 51.8. Let $f: \mathbb{R}^n \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$ be any function. The function whose epigraph is the closure of the epigraph $\text{epi}(f)$ of f (in \mathbb{R}^{n+1}) is called the *lower semi-continuous hull* of f . If f is a convex function and if $f(x) > -\infty$ for all $x \in \mathbb{R}^n$, then the *closure* $\text{cl}(f)$ of f is equal to its lower semi-continuous hull, else if $f(x) = -\infty$ for some $x \in \mathbb{R}^n$, then the *closure* $\text{cl}(f)$ of f is the constant function with value $-\infty$. A convex function f is *closed* if $f = \text{cl}(f)$.

Definition 51.8 implies that there are *only two closed improper convex functions*: the constant function with value $-\infty$ and the constant function with value $+\infty$. Also, by Proposition 51.3, *a proper convex function is closed iff it is equal to its lower semi-continuous hull iff its epigraph is nonempty and closed*.

Given a convex set C in \mathbb{R}^n , the interior $\text{int}(C)$ of C (the largest open subset of \mathbb{R}^n contained in C) is often not interesting because C may have dimension smaller than n . For example, a (closed) triangle in \mathbb{R}^3 has empty interior.

The remedy is to consider the affine hull $\text{aff}(C)$ of C , which is the smallest affine set containing C ; see Section 44.2. The dimension of C is the dimension of $\text{aff}(C)$. Then the relative interior of C is the interior of C in $\text{aff}(C)$ endowed with the subspace topology induced on $\text{aff}(C)$. More explicitly, we can make the following definition.

Definition 51.9. Let C be a subset of \mathbb{R}^n . The *relative interior* of C is the set

$$\text{relint}(C) = \{x \in C \mid B_\epsilon(x) \cap \text{aff}(C) \subseteq C \quad \text{for some } \epsilon > 0\},$$

where $B_\epsilon(x) = \{y \in \mathbb{R}^n \mid \|x - y\|_2 < \epsilon\}$, the open ball of center x and radius ϵ . The *relative boundary* of C is defined as $\overline{C} - \text{relint}(C)$, where \overline{C} is the closure of C in \mathbb{R}^n (the smallest closed subset of \mathbb{R}^n containing C).

Remark. Observe that $\text{int}(C) \subseteq \text{relint}(C)$. Rockafellar denotes the relative interior of a set C by $\text{ri}(C)$.

The following result from Rockafellar [138] (Theorem 7.2) tells us that an improper convex function mostly takes infinite values, except perhaps at relative boundary points of its effective domain.

Proposition 51.4. *If f is an improper convex function, then $f(x) = -\infty$ for every $x \in \text{relint}(\text{dom}(f))$. Thus an improper convex function takes infinite values, except at relative boundary points of its effective domain.*

Example 51.2 illustrates Proposition 51.4.

The following result also holds; see Rockafellar [138] (Corollary 7.2.3).

Proposition 51.5. *If f is a convex function whose effective domain is relatively open, which means that $\text{relint}(\text{dom}(f)) = \text{dom}(f)$, then either $f(x) > -\infty$ for all $x \in \mathbb{R}^n$, or $f(x) = \pm\infty$ for all $x \in \mathbb{R}^n$.*

We also have the following result showing that the closure of a proper convex function does not differ much from the original function; see Rockafellar [138] (Theorem 7.4).

Proposition 51.6. *Let $f: \mathbb{R}^n \rightarrow \mathbb{R} \cup \{+\infty\}$ be a proper convex function. Then $\text{cl}(f)$ is a closed proper convex function, and $\text{cl}(f)$ agrees with f on $\text{dom}(f)$ except possibly at relative boundary points.*

Example 51.3. For an example of Propositions 51.6 and 51.5, let $f: \mathbb{R} \rightarrow \mathbb{R} \cup \{+\infty\}$ be the proper convex function

$$f(x) = \begin{cases} x^2 & \text{if } x < 1 \\ +\infty & \text{if } |x| \geq 1. \end{cases}$$

Then $\text{cl}(f)$ is

$$\text{clf}(x) = \begin{cases} x^2 & \text{if } x \leq 1 \\ +\infty & \text{if } |x| > 1, \end{cases}$$

and $\text{clf}(x) = f(x)$ whenever $x \in (-\infty, 1) = \text{relint}(\text{dom}(f)) = \text{dom}(f)$. Furthermore, since $\text{relint}(\text{dom}(f)) = \text{dom}(f)$, $f(x) > -\infty$ for all $x \in \mathbb{R}$. See Figure 51.5.

Small miracle: the indicator function I_C of any closed convex set is proper and closed. Indeed, for any $\alpha \in \mathbb{R}$ the sublevel set $\{x \in \mathbb{R}^n \mid I_C(x) \leq \alpha\}$ is either empty if $\alpha < 0$, or equal to C if $\alpha \geq 0$, and C is closed.

We now discuss briefly continuity properties of convex functions. The fact that a convex function f can take the values $\pm\infty$ causes a difficulty, so we consider the restriction of f to its effective domain. There is still a problem because an improper function may take the value $-\infty$. However, if we consider any subset C of $\text{dom}(f)$ which is relatively open, which means that $\text{relint}(C) = C$, then $C \subseteq \text{relint}(\text{dom}(f))$, so by Proposition 51.4, the function

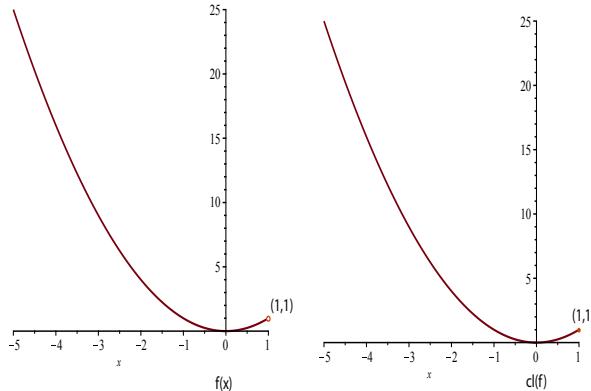

Figure 51.5: The proper convex function of Example 51.3 and its closure. These two functions only differ at the relative boundary point of $\text{dom}(f)$, namely $x = 1$.

f has the constant value $-\infty$ on C , and so it can be considered to be continuous on C . Thus we are led to consider proper functions.

Definition 51.10. Given a proper convex function f , for any subset $S \subseteq \text{dom}(f)$, we say that f is *continuous relative to S* if the restriction of f to S is continuous, with S endowed with the subspace topology.

The following result is proven in Rockafellar [138] (Theorem 10.1).

Proposition 51.7. *If f is a proper convex function, then f is continuous on any convex relatively open subset C ($\text{relint}(C) = C$) contained in its effective domain $\text{dom}(f)$, in particular relative to $\text{relint}(\text{dom}(f))$.*

As a corollary, any convex function f which is finite on \mathbb{R}^n is continuous.

The behavior of a convex function at relative boundary points of the effective domain can be tricky. Here is an example due to Rockafellar [138] illustrating the problems.

Example 51.4. Consider the proper convex function (on \mathbb{R}^2) given by

$$f(x, y) = \begin{cases} y^2/(2x) & \text{if } x > 0 \\ 0 & \text{if } x = 0, y = 0 \\ +\infty & \text{otherwise.} \end{cases}$$

We have

$$\text{dom}(f) = \{(x, y) \in \mathbb{R}^2 \mid x > 0\} \cup \{(0, 0)\}.$$

See Figure 51.6.

The function f is continuous on the open right half-plane $\{(x, y) \in \mathbb{R}^2 \mid x > 0\}$, but not at $(0, 0)$. The limit of $f(x, y)$ when (x, y) approaches $(0, 0)$ on the parabola of equation

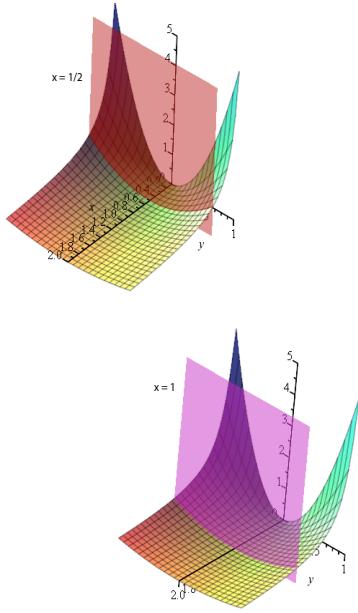

Figure 51.6: The proper convex function of Example 51.4. When intersected by vertical planes of the form $x = \alpha$, for $\alpha > 0$, the trace is an upward parabola. When α is close to zero, this parabola approximates the positive z axis.

$x = y^2/(2\alpha)$ is α for any $\alpha > 0$. See Figure 51.7 However, it is easy to see that the limit along any line segment from $(0, 0)$ to a point in the open right half-plane is 0.

We conclude this quick tour of the basic properties of convex functions with a result involving the Lipschitz condition.

Definition 51.11. Let $f: E \rightarrow F$ be a function between normed vector spaces E and F , and let U be a nonempty subset of E . We say that f *Lipschitzian on U* (or *has the Lipschitz condition on U*) if there is some $c \geq 0$ such that

$$\|f(x) - f(y)\|_F \leq c \|x - y\|_E \quad \text{for all } x, y \in U.$$

Obviously, if f is Lipschitzian on U it is uniformly continuous on U . The following result is proven in Rockafellar [138] (Theorem 10.4).

Proposition 51.8. *Let f be a proper convex function, and let S be any (nonempty) closed bounded subset of $\text{relint}(\text{dom}(f))$. Then f is Lipschitzian on S .*

In particular, a finite convex function on \mathbb{R}^n is Lipschitzian on every compact subset of \mathbb{R}^n . However, such a function may not be Lipschitzian on \mathbb{R}^n as a whole.

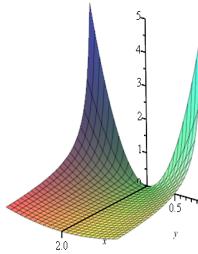

Figure a

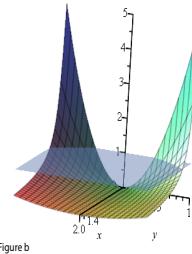

Figure b

Figure 51.7: Figure (a) illustrates the proper convex function of Example 51.4. Figure (b) illustrates the approach to $(0,0)$ along the planar parabolic curve $(y^2/2, y)$. Then $f(y^2/2, y) = 1$ and Figure b shows the intersection of the surface with the plane $z = 1$.

51.2 Subgradients and Subdifferentials

We saw in the previous section that proper convex functions have “good” continuity properties. Remarkably, if f is a convex function, for any $x \in \mathbb{R}^n$ such that $f(x)$ is finite, the one-sided derivative $f'(x; u)$ exists for all $u \in \mathbb{R}^n$; This result has been shown at least since 1893, as noted by Stoltz (see Rockafellar [138], page 428). Directional derivatives will be discussed in Section 51.3. If f is differentiable at x , then of course

$$df_x(u) = \langle \nabla f_x, u \rangle \quad \text{for all } u \in \mathbb{R}^n,$$

where ∇f_x is the gradient of f at x .

But even if f is not differentiable at x , it turns out that for “most” $x \in \text{dom}(f)$, in particular if $x \in \text{relint}(\text{dom}(f))$, there is a nonempty closed convex set $\partial f(x)$ which may be viewed as a generalization of the gradient ∇f_x . This convex set of \mathbb{R}^n , $\partial f(x)$, called the *subdifferential of f at x* , has some of the properties of the gradient ∇f_x . The vectors in $\partial f(x)$ are called *subgradients* at x . For example, if f is a proper convex function, then f achieves its minimum at $x \in \mathbb{R}^n$ iff $0 \in \partial f(x)$. Some of the theorems of Chapter 50 can be generalized to convex functions that are not necessarily differentiable by replacing conditions involving gradients by conditions involving subdifferentials. These generalizations are crucial for the justification that various iterative methods for solving optimization programs converge. For

example, they are used to prove the convergence of the ADMM method discussed in Chapter 52.

One should note that the notion of subdifferential is not just a gratuitous mathematical generalization. The remarkable fact that the optimization problem

$$\begin{aligned} & \text{minimize} && J(u) \\ & \text{subject to} && u \in C, \end{aligned}$$

where C is a closed convex set in \mathbb{R}^n can be rewritten as

$$\begin{aligned} & \text{minimize} && J(u) + I_C(z) \\ & \text{subject to} && u - z = 0, \end{aligned}$$

where I_C is the indicator function of C , forces us to deal with functions such as $J(u) + I_C(z)$ which are not differentiable, even if J is. ADMM can cope with this situation (under certain conditions), and subdifferentials cannot be avoided in justifying its convergence. However, it should be said that the subdifferential $\partial f(x)$ is a theoretical tool that is never computed in practice (except in very special simple cases).

To define subgradients we need to review (affine) hyperplanes.

Recall that an *affine form* $\varphi: \mathbb{R}^n \rightarrow \mathbb{R}$ is a function of the form

$$\varphi(x) = h(x) + c, \quad x \in \mathbb{R}^n,$$

where $h: \mathbb{R}^n \rightarrow \mathbb{R}$ is a linear form and $c \in \mathbb{R}$ is some constant. An *affine hyperplane* $H \subseteq \mathbb{R}^n$ is the kernel of any nonconstant affine form $\varphi: \mathbb{R}^n \rightarrow \mathbb{R}$ (which means that the linear form h defining φ is not the zero linear form),

$$H = \varphi^{-1}(0) = \{x \in \mathbb{R}^n \mid \varphi(x) = 0\}.$$

Any two nonconstant affine forms φ and ψ defining the same (affine) hyperplane H , in the sense that $H = \varphi^{-1}(0) = \psi^{-1}(0)$, must be proportional, which means that there is some nonzero $\alpha \in \mathbb{R}$ such that $\psi = \alpha\varphi$.

A nonconstant affine form φ also defines the two *half spaces* H_+ and H_- given by

$$H_+ = \{x \in \mathbb{R}^n \mid \varphi(x) \geq 0\}, \quad H_- = \{x \in \mathbb{R}^n \mid \varphi(x) \leq 0\}.$$

Clearly, $H_+ \cap H_- = H$, their common boundary. See Figure 51.8. The choice of sign is somewhat arbitrary, since the affine form $\alpha\varphi$ with $\alpha < 0$ defines the half spaces with H_- and H_+ (the half spaces are swapped).

By the duality induced by the Euclidean inner product on \mathbb{R}^n , a linear form $h: \mathbb{R}^n \rightarrow \mathbb{R}$ corresponds to a *unique* vector $u \in \mathbb{R}^n$ such that

$$h(x) = \langle x, u \rangle \quad \text{for all } x \in \mathbb{R}^n.$$

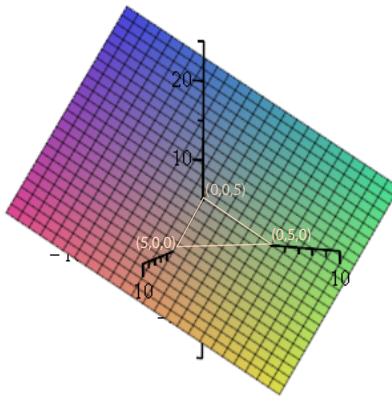

Figure 51.8: The affine hyperplane $H = \{x \in \mathbb{R}^3 \mid x + y + z - 2 = 0\}$. The half space H_+ faces the viewer and contains the point $(0, 0, 10)$, while the half space H_- is behind H and contains the point $(0, 0, 0)$.

Then if φ is the affine form given by $\varphi(x) = \langle x, u \rangle + c$, this affine form is nonconstant iff $u \neq 0$, and u is normal to the hyperplane H , in the sense that if $x_0 \in H$ is any fixed vector in H , and x is any vector in H , then $\langle x - x_0, u \rangle = 0$.

Indeed, $x_0 \in H$ means that $\langle x_0, u \rangle + c = 0$, and $x \in H$ means that $\langle x, u \rangle + c = 0$, so we get $\langle x_0, u \rangle = \langle x, u \rangle$, which implies $\langle x - x_0, u \rangle = 0$.

Here is an observation which plays a key role in defining the notion of subgradient. An illustration of the following proposition is provided by Figure 51.9.

Proposition 51.9. *Let $\varphi: \mathbb{R}^n \rightarrow \mathbb{R}$ be a nonconstant affine form. Then the map $\omega: \mathbb{R}^{n+1} \rightarrow \mathbb{R}$ given by*

$$\omega(x, \alpha) = \varphi(x) - \alpha, \quad x \in \mathbb{R}^n, \alpha \in \mathbb{R},$$

is a nonconstant affine form defining a hyperplane $\mathcal{H} = \omega^{-1}(0)$ which is the graph of the affine form φ . Furthermore, this hyperplane is nonvertical in \mathbb{R}^{n+1} , in the sense that \mathcal{H} cannot be defined by a nonconstant affine form $(x, \alpha) \mapsto \psi(x)$ which does not depend on α .

Proof. Indeed, φ is of the form $\varphi(x) = h(x) + c$ for some nonzero linear form h , so

$$\omega(x, \alpha) = h(x) - \alpha + c.$$

Since h is linear, the map $(x, \alpha) = h(x) - \alpha$ is obviously linear and nonzero, so ω is a nonconstant affine form defining a hyperplane \mathcal{H} in \mathbb{R}^{n+1} . By definition,

$$\mathcal{H} = \{(x, \alpha) \in \mathbb{R}^{n+1} \mid \omega(x, \alpha) = 0\} = \{(x, \alpha) \in \mathbb{R}^{n+1} \mid \varphi(x) - \alpha = 0\},$$

which is the graph of φ . If \mathcal{H} was a vertical hyperplane, then \mathcal{H} would be defined by a nonconstant affine form ψ independent of α , but the affine form ω given by $\omega(x, \alpha) = \varphi(x) - \alpha$ and the affine form $\psi(x)$ can't be proportional, a contradiction. \square

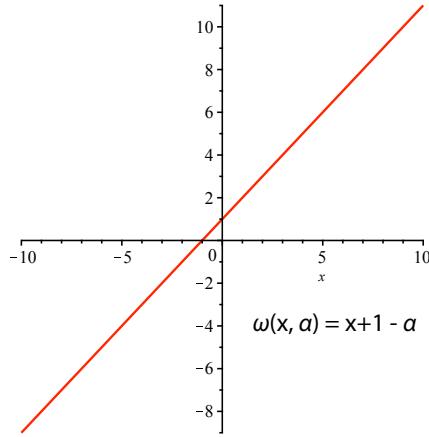

Figure 51.9: Let $\varphi: \mathbb{R} \rightarrow \mathbb{R}$ be the affine form $\varphi(x) = x + 1$. Let $\omega: \mathbb{R}^2 \rightarrow \mathbb{R}$ be the affine form $\omega(x, \alpha) = x + 1 - \alpha$. The hyperplane $\mathcal{H} = \omega^{-1}(0)$ is the red line with equation $x - \alpha + 1 = 0$.

We say that \mathcal{H} is the *hyperplane (in \mathbb{R}^{n+1}) induced by the affine form $\varphi: \mathbb{R}^n \rightarrow \mathbb{R}$* . Also recall the notion of supporting hyperplane to a convex set.

Definition 51.12. If C is a nonempty convex set in \mathbb{R}^n and x is a vector in C , an affine hyperplane H is a *supporting hyperplane to C at x* if

- (1) $x \in H$.
- (2) Either $C \subseteq H_+$ or $C \subseteq H_-$.

See Figure 51.10. Equivalently, there is some nonconstant affine form φ such that $\varphi(z) = \langle z, u \rangle - c$ for all $z \in \mathbb{R}^n$, for some nonzero $u \in \mathbb{R}^n$ and some $c \in \mathbb{R}$, such that

- (1) $\langle x, u \rangle = c$.
- (2) $\langle z, u \rangle \leq c$ for all $z \in C$

The notion of vector normal to a cone is defined as follows.

Definition 51.13. Given a nonempty convex set C in \mathbb{R}^n , for any $a \in C$, a vector $u \in \mathbb{R}^n$ is *normal to C at a* if

$$\langle z - a, u \rangle \leq 0 \quad \text{for all } z \in C.$$

In other words, u does not make an acute angle with any line segment in C with a as endpoint. The set of all vectors u normal to C is called the *normal cone* to C at a and is denoted by $N_C(a)$. See Figure 51.11.

It is easy to check that the normal cone to C at a is a convex cone. Also, if the hyperplane H defined by an affine form $\varphi(z) = \langle z, u \rangle - c$ with $u \neq 0$ is a supporting hyperplane to C at

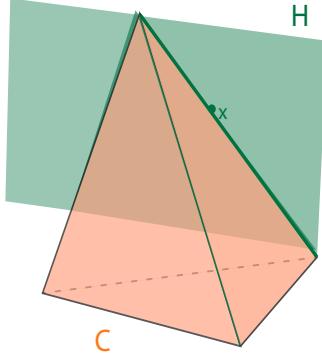

Figure 51.10: Let C be the solid peach tetrahedron in \mathbb{R}^3 . The green plane H is a supporting hyperplane to the point x since $x \in H$ and $C \subseteq H_+$, i.e. H only intersects C on the edge containing x and so the tetrahedron lies in “front” of H .

x , since $\langle z, u \rangle \leq c$ for all $z \in C$ and $\langle x, u \rangle = c$, we have $\langle z - x, u \rangle \leq 0$ for all $z \in C$, which means that u is normal to C at x . This concept is illustrated by Figure 51.12.

The notion of subgradient can be motivated as follows. A function $f: \mathbb{R}^n \rightarrow \mathbb{R}$ is differentiable at $x \in \mathbb{R}^n$ if

$$f(x + y) = f(x) + df_x(y) + \epsilon(y) \|y\|_2,$$

for all $y \in \mathbb{R}^n$ in some nonempty subset containing x , where $df_x: \mathbb{R}^n \rightarrow \mathbb{R}$ is a linear form, and ϵ is some function such that $\lim_{\|y\|_2 \rightarrow 0} \epsilon(y) = 0$. Furthermore,

$$df_x(y) = \langle y, \nabla f_x \rangle \quad \text{for all } y \in \mathbb{R}^n,$$

where ∇f_x is the gradient of f at x , so

$$f(x + y) = f(x) + \langle y, \nabla f_x \rangle + \epsilon(y) \|y\|_2.$$

If we assume that f is convex, it makes sense to replace the equality sign by the inequality sign \geq in the above equation and to drop the “error term” $\epsilon(y) \|y\|_2$, so a vector u is a subgradient of f at x if

$$f(x + y) \geq f(x) + \langle y, u \rangle \quad \text{for all } y \in \mathbb{R}^n.$$

Thus we are led to the following definition.

Definition 51.14. Let $f: \mathbb{R}^n \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$ be a convex function. For any $x \in \mathbb{R}^n$, a subgradient of f at x is any vector $u \in \mathbb{R}^n$ such that

$$f(z) \geq f(x) + \langle z - x, u \rangle, \quad \text{for all } z \in \mathbb{R}^n. \tag{*_{\text{subgrad}}}$$

The above inequality is called the *subgradient inequality*. The set of all subgradients of f at x is denoted $\partial f(x)$ and is called the *subdifferential* of f at x . If $\partial f(x) \neq \emptyset$, then we say that f is *subdifferentiable* at x .

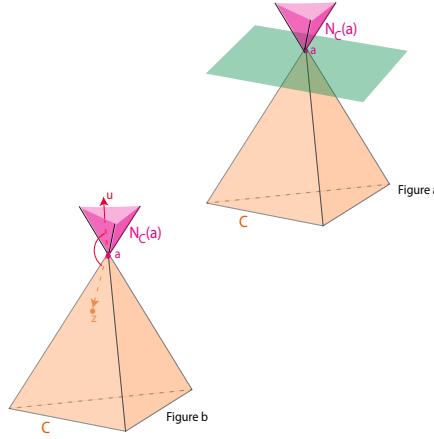

Figure 51.11: Let C be the solid peach tetrahedron in \mathbb{R}^3 . The small upside-down magenta tetrahedron is the translate of $N_C(a)$. Figure (a) shows that the normal cone is separated from C by the horizontal green supporting hyperplane. Figure (b) shows that any vector $u \in N_C(a)$ does not make an acute angle with a line segment in C emanating from a .

Assume that $f(x)$ is finite. Observe that the subgradient inequality says that 0 is a subgradient at x iff f has a global minimum at x . In this case, the hyperplane \mathcal{H} (in \mathbb{R}^{n+1}) defined by the affine form $\omega(x, \alpha) = f(x) - \alpha$ is a horizontal supporting hyperplane to the epigraph $\text{epi}(f)$ at $(x, f(x))$. If $u \in \partial f(x)$ and $u \neq 0$, then (\ast_{subgrad}) says that the hyperplane induced by the affine form $z \mapsto \langle z - x, u \rangle + f(x)$ as in Proposition 51.9 is a nonvertical supporting hyperplane \mathcal{H} (in \mathbb{R}^{n+1}) to the epigraph $\text{epi}(f)$ at $(x, f(x))$. The vector $(u, -1) \in \mathbb{R}^{n+1}$ is normal to the hyperplane \mathcal{H} . See Figure 51.13.

Indeed, if $u \neq 0$, the hyperplane \mathcal{H} is given by

$$\mathcal{H} = \{(y, \alpha) \in \mathbb{R}^{n+1} \mid \omega(y, \alpha) = 0\}$$

with $\omega(y, \alpha) = \langle y - x, u \rangle + f(x) - \alpha$, so $\omega(x, f(x)) = 0$, which means that $(x, f(x)) \in \mathcal{H}$. Also, for any $(z, \beta) \in \text{epi}(f)$, by (\ast_{subgrad}) , we have

$$\omega(z, \beta) = \langle z - x, u \rangle + f(x) - \beta \leq f(z) - \beta \leq 0,$$

since $(z, \beta) \in \text{epi}(f)$, so $\text{epi}(f) \subseteq \mathcal{H}_-$, and \mathcal{H} is a nonvertical supporting hyperplane (in \mathbb{R}^{n+1}) to the epigraph $\text{epi}(f)$ at $(x, f(x))$. Since

$$\omega(y, \alpha) = \langle y - x, u \rangle + f(x) - \alpha = \langle (y - x, \alpha), (u, -1) \rangle + f(x),$$

the vector $(u, -1)$ is indeed normal to the hyperplane \mathcal{H} .

The above facts are important and recorded as the following proposition.

Proposition 51.10. *If $f(x)$ is finite, then f is subdifferentiable at x if and only if there is a nonvertical supporting hyperplane (in \mathbb{R}^{n+1}) to the epigraph $\text{epi}(f)$ at $(x, f(x))$. In this*

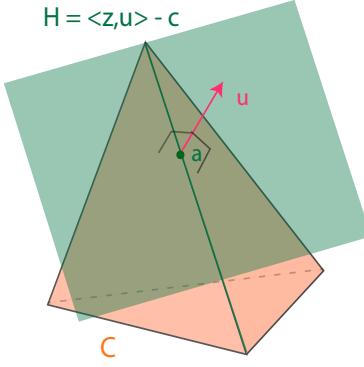

Figure 51.12: Let C be the solid peach tetrahedron in \mathbb{R}^3 . The green plane H defined by $\varphi(z) = \langle z, u \rangle - c$ is a supporting hyperplane to C at a . The pink normal to H , namely the vector u , is also normal to C at a .

case, there is a linear form φ (over \mathbb{R}^n) such that $f(x) \geq \varphi(x)$ for all $x \in \mathbb{R}^n$. We can pick φ given by $\varphi(y) = \langle y - x, u \rangle + f(x)$ for all $y \in \mathbb{R}^n$.

It is easy to see that $\partial f(x)$ is closed and convex. The set $\partial f(x)$ may be empty, or reduced to a single element. In $\partial f(x)$ consists of a single element it can be shown that f is finite near x , differentiable at x , and that $\partial f(x) = \{\nabla f_x\}$, the gradient of f at x .

Example 51.5. The ℓ^2 norm $f(x) = \|x\|_2$ is subdifferentiable for all $x \in \mathbb{R}^n$, in fact differentiable for all $x \neq 0$. For $x = 0$, the set $\partial f(0)$ consists of all $u \in \mathbb{R}^n$ such that

$$\|z\|_2 \geq \langle z, u \rangle \quad \text{for all } z \in \mathbb{R}^n,$$

namely (by Cauchy–Schwarz), the Euclidean unit ball $\{u \in \mathbb{R}^n \mid \|u\|_2 \leq 1\}$. See Figure 51.14.

Example 51.6. For the ℓ^∞ norm if $f(x) = \|x\|_\infty$, we leave it as an exercise to show that $\partial f(0)$ is the polyhedron

$$\partial f(0) = \text{conv}\{\pm e_1, \dots, \pm e_n\}.$$

See Figure 51.15. One can also work out what is $\partial f(x)$ if $x \neq 0$, but this is more complicated; see Rockafellar [138], page 215.

Example 51.7. The following function is an example of a proper convex function which is not subdifferentiable everywhere:

$$f(x) = \begin{cases} -(1 - |x|^2)^{1/2} & \text{if } |x| \leq 1 \\ +\infty & \text{otherwise.} \end{cases}$$

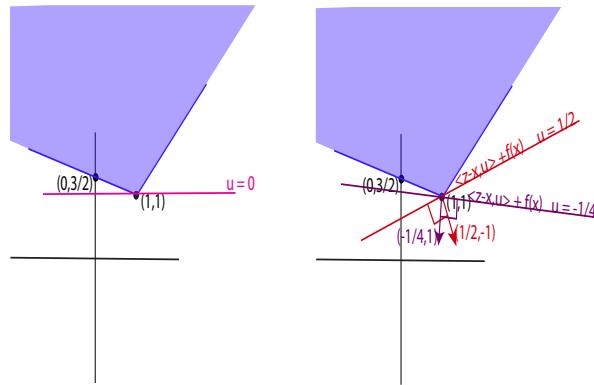

Figure 51.13: Let $f: \mathbb{R} \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$ be the piecewise function defined by $f(x) = x + 1$ for $x \geq 1$ and $f(x) = -\frac{1}{2}x + \frac{3}{2}$ for $x < 1$. Its epigraph is the shaded blue region in \mathbb{R}^2 . Since f has minimum at $x = 1$, $0 \in \partial f(1)$, and the graph of $f(x)$ has a horizontal supporting hyperplane at $(1, 1)$. Since $\{\frac{1}{2}, -\frac{1}{4}\} \subset \partial f(1)$, the maroon line $\frac{1}{2}(x - 1) + 1$ (with normal $(\frac{1}{2}, -1)$) and the violet line $-\frac{1}{4}(x - 1) + 1$ (with normal $(-\frac{1}{4}, -1)$) are supporting hyperplanes to the graph of $f(x)$ at $(1, 1)$.

See Figure 51.16. We leave it as an exercise to show that f is subdifferentiable (in fact differentiable) at x when $|x| < 1$, but $\partial f(x) = \emptyset$ when $|x| \geq 1$, even though $x \in \text{dom}(f)$ for $|x| = 1$.

Example 51.8. The subdifferential of an indicator function is interesting. Let C be a nonempty convex set. By definition, $u \in \partial I_C(x)$ iff

$$I_C(z) \geq I_C(x) + \langle z - x, u \rangle \quad \text{for all } z \in \mathbb{R}^n.$$

Since C is nonempty, there is some $z \in C$ such that $I_C(z) = 0$, so the above condition implies that $x \in C$ (otherwise $I_C(x) = +\infty$ but $0 \geq +\infty + \langle z - u, u \rangle$ is impossible), so $0 \geq \langle z - x, u \rangle$ for all $z \in C$, which means that z is normal to C at x . Therefore, $\partial I_C(x)$ is the normal cone $N_C(x)$ to C at x .

Example 51.9. The subdifferentials of the indicator function f of the nonnegative orthant of \mathbb{R}^n reveal a connection to complementary slackness conditions. Recall that this indicator function is given by

$$f(x_1, \dots, x_n) = \begin{cases} 0 & \text{if } x_i \geq 0, 1 \leq i \leq n, \\ +\infty & \text{otherwise.} \end{cases}$$

By Example 51.8, the subgradients y of f at $x \geq 0$ form the normal cone to the nonnegative orthant at x . This means that $y \in N_C(x)$ iff

$$\langle z - x, y \rangle \leq 0 \quad \text{for all } z \geq 0$$

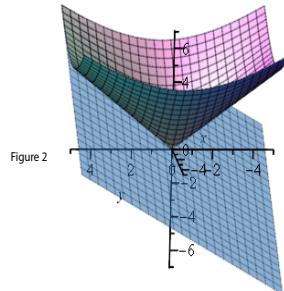

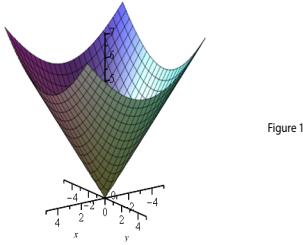

Figure 51.14: Figure (1) shows the graph in \mathbb{R}^3 of $f(x, y) = \|(x, y)\|_2 = \sqrt{x^2 + y^2}$. Figure (2) shows the supporting hyperplane with normal $(\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}, -1)$, where $(\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}) \in \partial f(0)$.

iff

$$\langle z, y \rangle \leq \langle x, y \rangle \quad \text{for all } z \geq 0.$$

In particular, for $z = 0$ we get $\langle x, y \rangle \geq 0$, and for $z = 2x \geq 0$, we have $\langle x, y \rangle \leq 0$, so $\langle x, y \rangle = 0$. As a consequence, $y \in N_C(x)$ iff $\langle x, y \rangle = 0$ and

$$\langle z, y \rangle \leq 0 \quad \text{for all } z \geq 0.$$

For $z = e_j \geq 0$, we get $y_j \leq 0$. Conversely, if $y \leq 0$ and $\langle x, y \rangle = 0$, since $x \geq 0$, we get $\langle z, y \rangle \leq 0$ for all $z \geq 0$, and so

$$\partial f(x) = \{y = (y_1, \dots, y_n) \in \mathbb{R}^n \mid y \leq 0, \langle x, y \rangle = 0\}.$$

But for $x \geq 0$ and $y \leq 0$ we have $\langle x, y \rangle = \sum_{j=1}^n x_j y_j = 0$ iff $x_j y_j = 0$ for $j = 1, \dots, n$, thus we see that $y \in \partial f(x)$ iff we have

$$x_j \geq 0, y_j \leq 0, x_j y_j = 0, \quad 1 \leq j \leq n,$$

which are complementary slackness conditions.

Supporting hyperplanes to the epigraph of a proper convex function f can be used to prove a property which plays a key role in optimization theory. The proof uses a classical result of convex geometry, namely the Minkowski supporting hyperplane theorem.

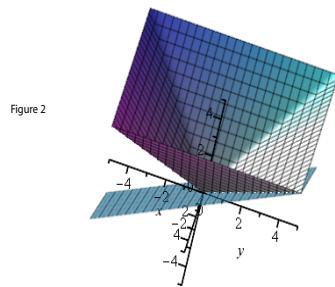

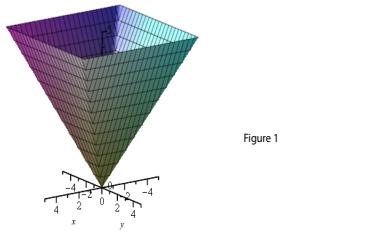

Figure 51.15: Figure (1) shows the graph in \mathbb{R}^3 of $f(x, y) = \|(x, y)\|_\infty = \sup\{|x|, |y|\}$. Figure (2) shows the supporting hyperplane with normal $(\frac{1}{2}, \frac{1}{2}, -1)$, where $(\frac{1}{2}, \frac{1}{2}) \in \partial f(0)$.

Theorem 51.11. (*Minkowski*) Let C be a nonempty convex set in \mathbb{R}^n . For any point $a \in C - \text{relint}(C)$, there is a supporting hyperplane H to C at a .

Theorem 51.11 is proven in Rockafellar [138] (Theorem 11.6). See also Berger [11] (Proposition 11.5.2). The proof is not as simple as one might expect, and is based on a geometric version of the Hahn–Banach theorem.

In order to prove Theorem 51.14 below we need two technical propositions.

Proposition 51.12. Let C be any nonempty convex set in \mathbb{R}^n . For any $x \in \text{relint}(C)$ and any $y \in \overline{C}$, we have $(1-\lambda)x + \lambda y \in \text{relint}(C)$ for all λ such that $0 \leq \lambda < 1$. In other words, the line segment from x to y including x and excluding y lies entirely within $\text{relint}(C)$.

Proposition 51.12 is proven in Rockafellar [138] (Theorem 6.1). The proof is not difficult but quite technical.

Proposition 51.13. For any proper convex function f on \mathbb{R}^n , we have

$$\text{relint}(\text{epi}(f)) = \{(x, \mu) \in \mathbb{R}^{n+1} \mid x \in \text{relint}(\text{dom}(f)), f(x) < \mu\}.$$

Proof. Proposition 51.13 is proven in Rockafellar [138] (Lemma 7.3). By working in the affine hull of $\text{epi}(f)$, the statement of Proposition 51.13 is equivalent to

$$\text{int}(\text{epi}(f)) = \{(x, \mu) \in \mathbb{R}^{n+1} \mid x \in \text{int}(\text{dom}(f)), f(x) < \mu\},$$

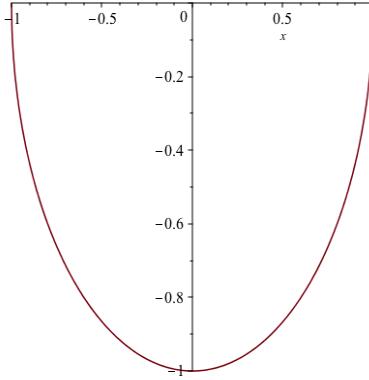

Figure 51.16: The graph of the function in Example 51.7.

assuming that the affine hull of $\text{epi}(f)$ has dimension $m + 1$. See Figure (1) of Figure 51.17. The inclusion \subseteq is obvious, so we only need to prove the reverse inclusion. Then for any $z \in \text{int}(\text{dom}(f))$, we can find a convex polyhedral subset $P = \text{conv}(a_1, \dots, a_{m+1})$ with $a_1, \dots, a_{m+1} \in \text{dom}(f)$ such that $z \in \text{int}(P)$. Let

$$\alpha = \max\{f(a_1), \dots, f(a_{m+1})\}.$$

Since any $x \in P$ can be expressed as

$$x = \lambda_1 a_1 + \dots + \lambda_{m+1} a_{m+1}, \quad \lambda_1 + \dots + \lambda_{m+1} = 1, \quad \lambda_i \geq 0,$$

and since f is convex we have

$$f(x) \leq \lambda_1 f(a_1) + \dots + \lambda_{m+1} f(a_{m+1}) \leq (\lambda_1 + \dots + \lambda_{m+1})\alpha = \alpha \quad \text{for all } x \in P.$$

The above shows that the open subset

$$\{(x, \mu) \in \mathbb{R}^{m+1} \mid x \in \text{int}(P), \mu < \alpha\}$$

is contained in $\text{epi}(f)$. See Figure (2) of Figure 51.17. In particular, for every $\mu > \alpha$, we have

$$(z, \mu) \in \text{int}(\text{epi}(f)).$$

Thus for any $\beta \in \mathbb{R}$ such that $\beta > f(z)$, we see that (z, β) belongs to the relative interior of the vertical line segment $\{(z, \mu) \in \mathbb{R}^{m+1} \mid f(z) \leq \mu \leq \alpha + \beta + 1\}$ which meets $\text{int}(\text{epi}(f))$. See Figure (3) of Figure 51.17. By Proposition 51.12, $(z, \beta) \in \text{int}(\text{epi}(f))$. \square

We can now prove the following important theorem.

Theorem 51.14. *Let f be a proper convex function on \mathbb{R}^n . For any $x \in \text{relint}(\text{dom}(f))$, there is a nonvertical supporting hyperplane \mathcal{H} to $\text{epi}(f)$ at $(x, f(x))$. Consequently f is subdifferentiable for all $x \in \text{relint}(\text{dom}(f))$, and there is some affine form $\varphi: \mathbb{R}^n \rightarrow \mathbb{R}$ such that $f(x) \geq \varphi(x)$ for all $x \in \mathbb{R}^n$.*

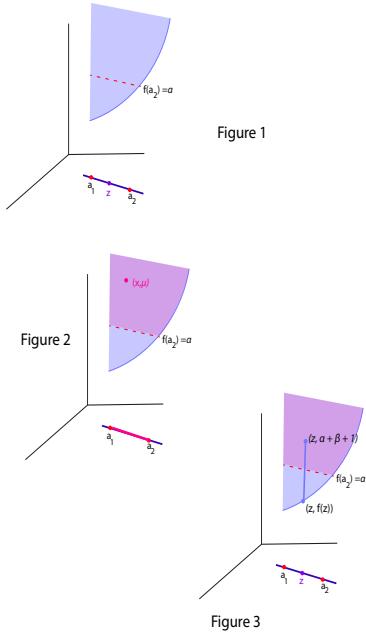

Figure 51.17: Figure (1) illustrates $\text{epi}(f)$, where $\text{epi}(f)$ is contained in a vertical plane of affine dimension 2. Figure (2) illustrates the magenta open subset $\{(x, \mu) \in \mathbb{R}^2 \mid x \in \text{int}(P), \alpha < \mu\}$ of $\text{epi}(f)$. Figure (3) illustrates the vertical line segment $\{(z, \mu) \in \mathbb{R}^2 \mid f(z) \leq \mu \leq a + \beta + 1\}$.

Proof. By Proposition 51.14, for any $x \in \text{relint}(\text{dom}(f))$, we have $(x, \mu) \in \text{relint}(\text{epi}(f))$ for all $\mu \in \mathbb{R}$ such that $f(x) < \mu$. Since by definition of $\text{epi}(f)$ we have $(x, f(x)) \in \text{epi}(f) - \text{relint}(\text{epi}(f))$, by Minkowski's theorem (Theorem 51.11), there is a supporting hyperplane \mathcal{H} to $\text{epi}(f)$ through $(x, f(x))$. Since $x \in \text{relint}(\text{dom}(f))$ and f is proper, the hyperplane \mathcal{H} is not a vertical hyperplane. By Definition 51.14, the function f is subdifferentiable at x , and the subgradient inequality shows that if we let $\varphi(z) = f(x) + \langle z - x, u \rangle$, then φ is an affine form such that $f(x) \geq \varphi(x)$ for all $x \in \mathbb{R}^n$. \square

Intuitively, a proper convex function can't decrease faster than an affine function. It is surprising how much work it takes to prove such an "obvious" fact.

Remark: Consider the proper convex function $f: \mathbb{R} \rightarrow \mathbb{R} \cup \{+\infty\}$ given by

$$f(x) = \begin{cases} -\sqrt{x} & \text{if } x \geq 0 \\ +\infty & \text{if } x < 0. \end{cases}$$

We have $\text{dom}(f) = [0, +\infty)$, f is differentiable for all $x > 0$, but it is not subdifferentiable

at $x = 0$. The only supporting hyperplane to $\text{epi}(f)$ at $(0, 0)$ is the vertical line of equation $x = 0$ (the y -axis) as illustrated by Figure 51.18.

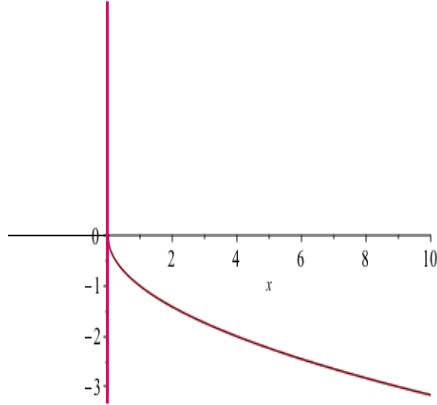

Figure 51.18: The graph of the partial function $f(x) = -\sqrt{x}$ and its red vertical supporting hyperplane at $x = 0$.

51.3 Basic Properties of Subgradients and Subdifferentials

A major tool to prove properties of subgradients is a variant of the notion of directional derivative.

Definition 51.15. Let $f: \mathbb{R}^n \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$ be any function. For any $x \in \mathbb{R}^n$ such that $f(x)$ is finite ($f(x) \in \mathbb{R}$), for any $u \in \mathbb{R}^n$, the *one-sided directional derivative* $f'(x; u)$ is defined to be the limit

$$f'(x; u) = \lim_{\lambda \downarrow 0} \frac{f(x + \lambda u) - f(x)}{\lambda}$$

if it exists ($-\infty$ and $+\infty$ being allowed as limits). See Figure 51.19. The above notation for the limit means that we consider the limit when $\lambda > 0$ tends to 0.

Note that

$$\lim_{\lambda \uparrow 0} \frac{f(x + \lambda u) - f(x)}{\lambda}$$

denotes the one-sided limit when $\lambda < 0$ tends to zero, and that

$$-f'(x; -u) = \lim_{\lambda \uparrow 0} \frac{f(x + \lambda u) - f(x)}{\lambda},$$

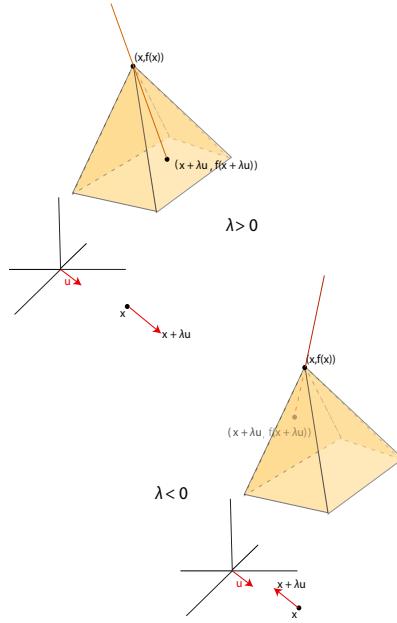

Figure 51.19: Let $f: \mathbb{R}^2 \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$ be the function whose graph (in \mathbb{R}^3) is the surface of the peach pyramid. The top figure illustrates that $f'(x; u)$ is the slope of the slanted burnt orange line, while the bottom figure depicts the line associated with $\lim_{\lambda \uparrow 0} \frac{f(x + \lambda u) - f(x)}{\lambda}$.

so the (two-sided) directional derivative $D_u f(x)$ exists iff $-f'(x; -u) = f'(x; u)$. Also, if f is differentiable at x , then

$$f'(x; u) = \langle \nabla f_x, u \rangle, \quad \text{for all } u \in \mathbb{R}^n,$$

where ∇f_x is the gradient of f at x . Here is the first remarkable result.

Proposition 51.15. *Let $f: \mathbb{R}^n \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$ be a convex function. For any $x \in \mathbb{R}^n$, if $f(x)$ is finite, then the function*

$$\lambda \mapsto \frac{f(x + \lambda u) - f(x)}{\lambda}$$

is a nondecreasing function of $\lambda > 0$, so that $f'(x; u)$ exists for any $u \in \mathbb{R}^n$, and

$$f'(x; u) = \inf_{\lambda > 0} \frac{f(x + \lambda u) - f(x)}{\lambda}.$$

Furthermore, $f'(x; u)$ is a positively homogeneous convex function of u (which means that $f'(x; \alpha u) = \alpha f'(x; u)$ for all $\alpha \in \mathbb{R}$ with $\alpha > 0$ and all $u \in \mathbb{R}^n$), $f'(x; 0) = 0$, and

$$-f'(x; -u) \leq f'(x; u) \quad \text{for all } u \in \mathbb{R}^n$$

Proposition 51.15 is proven in Rockafellar [138] (Theorem 23.1). The proof is not difficult but not very informative.

Remark: As a convex function of u , it can be shown that the effective domain of the function $u \mapsto f'(x; u)$ is the convex cone generated by $\text{dom}(f) - x$.

We will now state without proof some of the most important properties of subgradients and subdifferentials. Complete details can be found in Rockafellar [138] (Part V, Section 23).

In order to state the next proposition, we need the following definition.

Definition 51.16. For any convex set C in \mathbb{R}^n , the *support function* $\delta^*(-|C)$ of C is defined by

$$\delta^*(x|C) = \sup_{y \in C} \langle x, y \rangle, \quad x \in \mathbb{R}^n.$$

According to Definition 50.11, the conjugate of the indicator function I_C of a convex set C is given by

$$I_C^*(x) = \sup_{y \in \mathbb{R}^n} (\langle x, y \rangle - I_C(y)) = \sup_{y \in C} \langle x, y \rangle = \delta^*(x|C).$$

Thus $\delta^*(-|C) = I_C^*$, the conjugate of the indicator function I_C .

The following proposition relates directional derivatives at x and the subdifferential at x .

Proposition 51.16. Let $f: \mathbb{R}^n \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$ be a convex function. For any $x \in \mathbb{R}^n$, if $f(x)$ is finite, then a vector $u \in \mathbb{R}^n$ is a subgradient to f at x if and only if

$$f'(x; y) \geq \langle y, u \rangle \quad \text{for all } y \in \mathbb{R}^n.$$

Furthermore, the closure of the convex function $y \mapsto f'(x; y)$ is the support function of the closed convex set $\partial f(x)$, the subdifferential of f at x :

$$\text{cl}(f'(x; -)) = \delta^*(-|\partial f(x)).$$

Sketch of proof. Proposition 51.16 is proven in Rockafellar [138] (Theorem 23.2). We prove the inequality. If we write $z = x + \lambda y$ with $\lambda > 0$, then the subgradient inequality implies

$$f(x + \lambda u) \geq f(x) + \langle z - x, u \rangle = f(x) + \lambda \langle y, u \rangle,$$

so we get

$$\frac{f(x + \lambda y) - f(x)}{\lambda} \geq \langle y, u \rangle.$$

Since the expression on the left tends to $f'(x; y)$ as $\lambda > 0$ tends to zero, we obtain the desired inequality. The second part follows from Corollary 13.2.1 in Rockafellar [138]. \square

If f is a proper function on \mathbb{R} , then its effective domain being convex is an interval whose relative interior is an open interval (a, b) . In Proposition 51.16, we can pick $y = 1$ so $\langle y, u \rangle = u$, and for any $x \in (a, b)$, since the limits $f'_-(x) = -f'(x; -1)$ and $f'_+(x) = f'(x; 1)$ exist, with $f'_-(x) \leq f'_+(x)$, we deduce that $\partial f(x) = [f'_-(x), f'_+(x)]$. The numbers $\alpha \in [f'_-(x), f'_+(x)]$ are the slopes of nonvertical lines in \mathbb{R}^2 passing through $(x, f(x))$ that are supporting lines to the epigraph $\text{epi}(f)$ of f .

Example 51.10. If f is the celebrated **ReLU** function (ramp function) from deep learning defined so that

$$\text{ReLU}(x) = \max\{x, 0\} = \begin{cases} 0 & \text{if } x < 0 \\ x & \text{if } x \geq 0, \end{cases}$$

then $\partial \text{ReLU}(0) = [0, 1]$. See Figure 51.20. The function ReLU is differentiable for $x \neq 0$, with $\text{ReLU}'(x) = 0$ if $x < 0$ and $\text{ReLU}'(x) = 1$ if $x > 0$.

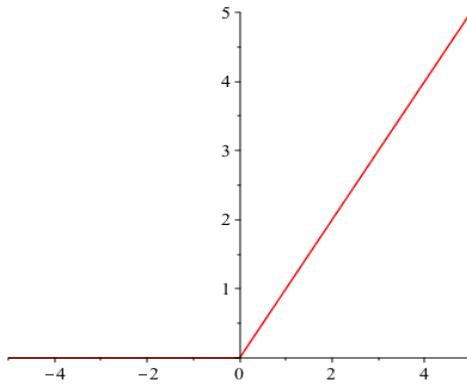

Figure 51.20: The graph of the ReLU function.

Proposition 51.16 has several interesting consequences.

Proposition 51.17. *Let $f: \mathbb{R}^n \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$ be a convex function. For any $x \in \mathbb{R}^n$, if $f(x)$ is finite and if f is subdifferentiable at x , then f is proper. If f is not subdifferentiable at x , then there is some $y \neq 0$ such that*

$$f'(x; y) = -f'(x; -y) = -\infty.$$

Proposition 51.17 is proven in Rockafellar [138] (Theorem 23.3). It confirms that improper convex functions are rather pathological objects, because if a convex function is subdifferentiable for some x such that $f(x)$ is finite, then f must be proper. This is because if $f(x)$ is finite, then the subgradient inequality implies that f majorizes an affine function, which is proper.

The next theorem is one of the most important results about the connection between one-sided directional derivatives and subdifferentials. It sharpens the result of Theorem 51.14.

Theorem 51.18. Let $f: \mathbb{R}^n \rightarrow \mathbb{R} \cup \{+\infty\}$ be a proper convex function. For any $x \notin \text{dom}(f)$, we have $\partial f(x) = \emptyset$. For any $x \in \text{relint}(\text{dom}(f))$, we have $\partial f(x) \neq \emptyset$, the map $y \mapsto f'(x; y)$ is convex, closed and proper, and

$$f'(x; y) = \sup_{u \in \partial f(x)} \langle y, u \rangle = \delta^*(y | \partial f(x)) \quad \text{for all } y \in \mathbb{R}^n.$$

The subdifferential $\partial f(x)$ is nonempty and bounded (also closed and convex) if and only if $x \in \text{int}(\text{dom}(f))$, in which case $f'(x; y)$ is finite for all $y \in \mathbb{R}^n$.

Theorem 51.18 is proven in Rockafellar [138] (Theorem 23.4). If we write

$$\text{dom}(\partial f) = \{x \in \mathbb{R}^n \mid \partial f(x) \neq \emptyset\},$$

then Theorem 51.18 implies that

$$\text{relint}(\text{dom}(f)) \subseteq \text{dom}(\partial f) \subseteq \text{dom}(f).$$

However, $\text{dom}(\partial f)$ is not necessarily convex as shown by the following counterexample.

Example 51.11. Consider the proper convex function defined on \mathbb{R}^2 given by

$$f(x, y) = \max\{g(x), |y|\},$$

where

$$g(x) = \begin{cases} 1 - \sqrt{x} & \text{if } x \geq 0 \\ +\infty & \text{if } x < 0. \end{cases}$$

See Figure 51.21. It is easy to see that $\text{dom}(f) = \{(x, y) \in \mathbb{R}^2 \mid x \geq 0\}$, but $\text{dom}(\partial f) = \{(x, y) \in \mathbb{R}^2 \mid x \geq 0\} - \{(0, y) \mid -1 < y < 1\}$, which is not convex.

The following theorem is important because it tells us when a convex function is differentiable in terms of its subdifferential, as shown in Rockafellar [138] (Theorem 25.1).

Theorem 51.19. Let f be a convex function on \mathbb{R}^n , and let $x \in \mathbb{R}^n$ such that $f(x)$ is finite. If f is differentiable at x then $\partial f(x) = \{\nabla f_x\}$ (where ∇f_x is the gradient of f at x) and we have

$$f(z) \geq f(x) + \langle z - x, \nabla f_x \rangle \quad \text{for all } z \in \mathbb{R}^n.$$

Conversely, if $\partial f(x)$ consists of a single vector, then $\partial f(x) = \{\nabla f_x\}$ and f is differentiable at x .

The first direction is easy to prove. Indeed, if f is differentiable at x , then

$$f'(x; y) = \langle y, \nabla f_x \rangle \quad \text{for all } y \in \mathbb{R}^n,$$

so by Proposition 51.16, a vector u is a subgradient at x iff

$$\langle y, \nabla f_x \rangle \geq \langle y, u \rangle \quad \text{for all } y \in \mathbb{R}^n,$$

so $\langle y, \nabla f_x - u \rangle \geq 0$ for all y , which implies that $u = \nabla f_x$.

We obtain the following corollary.

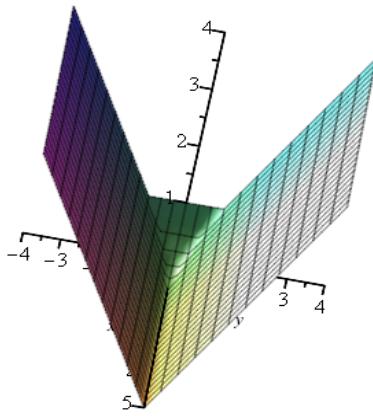

Figure 51.21: The graph of the function from Example 51.11 with a view along the positive x axis.

Corollary 51.20. *Let f be a convex function on \mathbb{R}^n , and let $x \in \mathbb{R}^n$ such that $f(x)$ is finite. If f is differentiable at x , then f is proper and $x \in \text{int}(\text{dom}(f))$.*

The following theorem shows that proper convex functions are differentiable almost everywhere.

Theorem 51.21. *Let f be a proper convex function on \mathbb{R}^n , and let D be the set of vectors where f is differentiable. Then D is a dense subset of $\text{int}(\text{dom}(f))$, and its complement in $\text{int}(\text{dom}(f))$ has measure zero. Furthermore, the gradient map $x \mapsto \nabla f_x$ is continuous on D .*

Theorem 51.21 is proven in Rockafellar [138] (Theorem 25.5).

Remark: If $f: (a, b) \rightarrow \mathbb{R}$ is a finite convex function on an open interval of \mathbb{R} , then the set D where f is differentiable is dense in (a, b) , and $(a, b) - D$ is at most countable. The map f' is continuous and nondecreasing on D . See Rockafellar [138] (Theorem 25.3).

We also have the following result showing that in “most cases” the subdifferential $\partial f(x)$ can be constructed from the gradient map; see Rockafellar [138] (Theorem 25.6).

Theorem 51.22. *Let f be a closed proper convex function on \mathbb{R}^n . If $\text{int}(\text{dom}(f)) \neq \emptyset$, then for every $x \in \text{dom}(f)$, we have*

$$\partial f(x) = \overline{\text{conv}(S(x))} + N_{\text{dom}(f)}(x)$$

where $N_{\text{dom}(f)}(x)$ is the normal cone to $\text{dom}(f)$ at x , and $S(x)$ is the set of all limits of sequences of the form $\nabla f_{x_1}, \nabla f_{x_2}, \dots, \nabla f_{x_p}, \dots$, where $x_1, x_2, \dots, x_p, \dots$ is a sequence in $\text{dom}(f)$ converging to x such that each ∇f_{x_p} is defined.

The next two results generalize familiar results about derivatives to subdifferentials.

Proposition 51.23. *Let f_1, \dots, f_n be proper convex functions on \mathbb{R}^n , and let $f = f_1 + \dots + f_n$. For $x \in \mathbb{R}^n$, we have*

$$\partial f(x) \supseteq \partial f_1(x) + \dots + \partial f_n(x).$$

If $\bigcap_{i=1}^n \text{relint}(\text{dom}(f_i)) \neq \emptyset$, then

$$\partial f(x) = \partial f_1(x) + \dots + \partial f_n(x).$$

Proposition 51.23 is proven in Rockafellar [138] (Theorem 23.8).

The next result can be viewed as a generalization of the chain rule.

Proposition 51.24. *Let f be the function given by $f(x) = h(Ax)$ for all $x \in \mathbb{R}^n$, where h is a proper convex function on \mathbb{R}^m and A is an $m \times n$ matrix. Then*

$$\partial f(x) \supseteq A^\top(\partial h(Ax)) \quad \text{for all } x \in \mathbb{R}^n.$$

If the range of A contains a point of $\text{relint}(\text{dom}(h))$, then

$$\partial f(x) = A^\top(\partial h(Ax)).$$

Proposition 51.24 is proven in Rockafellar [138] (Theorem 23.9).

51.4 Additional Properties of Subdifferentials

In general, if $f: \mathbb{R}^n \rightarrow \mathbb{R}$ is a function (not necessarily convex) and f is differentiable at x , we expect that the gradient ∇f_x of f at x is normal to the level set $\{z \in \mathbb{R}^n \mid f(z) = f(x)\}$ at $f(x)$. An analogous result, as illustrated in Figure 51.22, holds for proper convex functions in terms of subdifferentials.

Proposition 51.25. *Let f be a proper convex function on \mathbb{R}^n , and let $x \in \mathbb{R}^n$ be a vector such that f is subdifferentiable at x but f does not achieve its minimum at x . Then the normal cone $N_C(x)$ at x to the sublevel set $C = \{z \in \mathbb{R}^n \mid f(z) \leq f(x)\}$ is the closure of the convex cone spanned by $\partial f(x)$.*

Proposition 51.25 is proven in Rockafellar [138] (Theorem 23.7).

The following result sharpens Proposition 51.8.

Proposition 51.26. *Let f be a closed proper convex function on \mathbb{R}^n , and let S be a nonempty closed and bounded subset of $\text{int}(\text{dom}(f))$. Then*

$$\partial f(S) = \bigcup_{x \in S} \partial f(x)$$

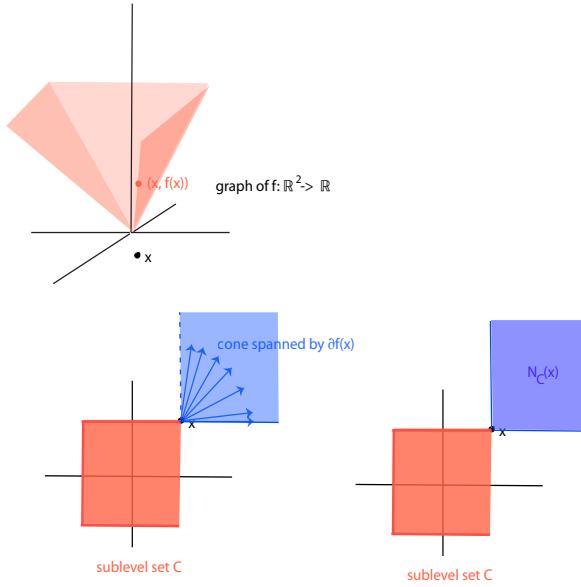

Figure 51.22: Let f be the proper convex function whose graph in \mathbb{R}^3 is the peach polyhedral surface. The sublevel set $C = \{z \in \mathbb{R}^2 \mid f(z) \leq f(x)\}$ is the orange square which is closed on three sides. Then the normal cone $N_C(x)$ is the closure of the convex cone spanned by $\partial f(x)$.

is nonempty, closed and bounded. If

$$\alpha = \sup_{y \in \partial f(S)} \|y\|_2 < +\infty,$$

then f is Lipschitzian on S , and we have

$$\begin{aligned} f'(x; z) &\leq \alpha \|z\|_2 && \text{for all } x \in S \text{ and all } z \in \mathbb{R}^n \\ |f(y) - f(x)| &\leq \alpha \|y - z\|_2 && \text{for all } x, y \in S. \end{aligned}$$

Proposition 51.24 is proven in Rockafellar [138] (Theorem 24.7).

The subdifferentials of a proper convex function f and its conjugate f^* are closely related. First, we have the following proposition from Rockafellar [138] (Theorem 12.2).

Proposition 51.27. *Let f be convex function on \mathbb{R}^n . The conjugate function f^* of f is a closed and convex function, proper iff f is proper. Furthermore, $(\text{cl}(f))^* = f^*$, and $f^{**} = \text{cl}(f)$.*

As a corollary of Proposition 51.27, it can be shown that

$$f^*(y) = \sup_{x \in \text{relint}(\text{dom}(f))} (\langle x, y \rangle - f(x)).$$

The following result is proven in Rockafellar [138] (Theorem 23.5).

Proposition 51.28. *For any proper convex function f on \mathbb{R}^n and for any vector $x \in \mathbb{R}^n$, the following conditions on a vector $y \in \mathbb{R}^n$ are equivalent.*

- (a) $y \in \partial f(x)$.
- (b) *The function $\langle z, y \rangle - f(z)$ achieves its supremum in z at $z = x$.*
- (c) $f(x) + f^*(y) \leq \langle x, y \rangle$.
- (d) $f(x) + f^*(y) = \langle x, y \rangle$.

If $(\text{cl}(f))(x) = f(x)$, then there are three more conditions all equivalent to the above conditions.

- (a*) $x \in \partial f^*(y)$.
- (b*) *The function $\langle x, z \rangle - f^*(z)$ achieves its supremum in z at $z = y$.*
- (a**) $y \in \partial(\text{cl}(f))(x)$.

The following results are corollaries of Proposition 51.28; see Rockafellar [138] (Corollaries 23.5.1, 23.5.2, 23.5.3).

Corollary 51.29. *For any proper convex function f on \mathbb{R}^n , if f is closed, then $y \in \partial f(x)$ iff $x \in \partial f^*(y)$, for all $x, y \in \mathbb{R}^n$.*

Corollary 51.29 states a sort of adjunction property.

Corollary 51.30. *For any proper convex function f on \mathbb{R}^n , if f is subdifferentiable at $x \in \mathbb{R}^n$, then $(\text{cl}(f))(x) = f(x)$ and $\partial(\text{cl}(f))(x) = \partial f(x)$.*

Corollary 51.30 shows that the closure of a proper convex function f agrees with f wherever f is subdifferentiable.

Corollary 51.31. *For any proper convex function f on \mathbb{R}^n , for any nonempty closed convex subset C of \mathbb{R}^n , for any $y \in \mathbb{R}^n$, the set $\partial\delta^*(y|C) = \partial I_C^*(y)$ consists of the vectors $x \in \mathbb{R}^n$ (if any) where the linear form $z \mapsto \langle z, y \rangle$ achieves its maximum over C .*

There is a notion of approximate subgradient which turns out to be useful in optimization theory; see Bertsekas [19, 17].

Definition 51.17. Let $f: \mathbb{R}^n \rightarrow \mathbb{R} \cup \{+\infty\}$ be any proper convex function. For any $\epsilon > 0$, for any $x \in \mathbb{R}^n$, if $f(x)$ is finite, then an ϵ -subgradient of f at x is any vector $u \in \mathbb{R}^n$ such that

$$f(z) \geq f(x) - \epsilon + \langle z - x, u \rangle, \quad \text{for all } z \in \mathbb{R}^n.$$

See Figure 51.23. The set of all ϵ -subgradients of f at x is denoted $\partial_\epsilon f(x)$ and is called the ϵ -subdifferential of f at x .

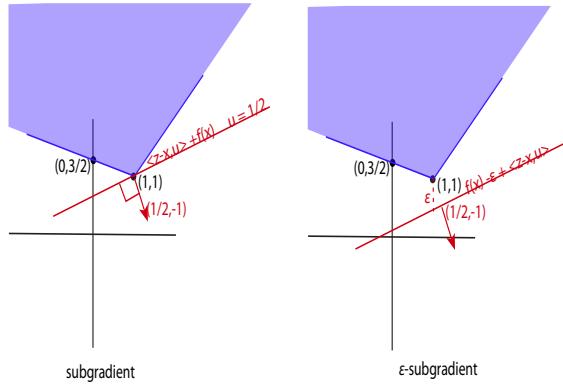

Figure 51.23: Let $f: \mathbb{R} \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$ be the piecewise function defined by $f(x) = x + 1$ for $x \geq 1$ and $f(x) = -\frac{1}{2}x + \frac{3}{2}$ for $x < 1$. Its epigraph is the shaded blue region in \mathbb{R}^2 . The line $\frac{1}{2}(x-1) + 1$ (with normal $(\frac{1}{2}, -1)$) is a supporting hyperplane to the graph of $f(x)$ at $(1, 1)$ while the line $\frac{1}{2}(x-1) + 1 - \epsilon$ is the hyperplane associated with the ϵ -subgradient at $x = 1$ and shows that $u = \frac{1}{2} \in \partial_\epsilon f(x)$.

The set $\partial_\epsilon f(x)$ can be defined in terms of the conjugate of the function h_x given by

$$h_x(y) = f(x+y) - f(x), \quad \text{for all } y \in \mathbb{R}^n.$$

Proposition 51.32. Let $f: \mathbb{R}^n \rightarrow \mathbb{R} \cup \{+\infty\}$ be any proper convex function. For any $\epsilon > 0$, if h_x is given by

$$h_x(y) = f(x+y) - f(x), \quad \text{for all } y \in \mathbb{R}^n,$$

then

$$h_x^*(y) = f^*(y) + f(x) - \langle x, y \rangle \quad \text{for all } y \in \mathbb{R}^n$$

and

$$\partial_\epsilon f(x) = \{u \in \mathbb{R}^n \mid h_x^*(u) \leq \epsilon\}.$$

Proof. We have

$$\begin{aligned} h_x^*(y) &= \sup_{z \in \mathbb{R}^n} (\langle y, z \rangle - h_x(z)) \\ &= \sup_{z \in \mathbb{R}^n} (\langle y, z \rangle - f(x+z) + f(x)) \\ &= \sup_{x+z \in \mathbb{R}^n} (\langle y, x+z \rangle - f(x+z) - \langle y, x \rangle + f(x)) \\ &= f^*(y) + f(x) - \langle x, y \rangle. \end{aligned}$$

Observe that $u \in \partial_\epsilon f(x)$ iff for every $y \in \mathbb{R}^n$,

$$f(x+y) \geq f(x) - \epsilon + \langle y, u \rangle$$

iff

$$\epsilon \geq \langle y, u \rangle - f(x+y) + f(x) = \langle y, u \rangle - h_x(y).$$

Since by definition

$$h_x^*(u) = \sup_{y \in \mathbb{R}^n} (\langle y, u \rangle - h_x(y)),$$

we conclude that

$$\partial_\epsilon f(x) = \{u \in \mathbb{R}^n \mid h_x^*(u) \leq \epsilon\},$$

as claimed. \square

Remark: By Fenchel's inequality $h_x^*(y) \geq 0$, and by Proposition 51.28(d), the set of vectors where h_x^* vanishes is $\partial f(x)$.

The equation $\partial_\epsilon f(x) = \{u \in \mathbb{R}^n \mid h_x^*(u) \leq \epsilon\}$ shows that $\partial_\epsilon f(x)$ is a closed convex set. As ϵ gets smaller, the set $\partial_\epsilon f(x)$ decreases, and we have

$$\partial f(x) = \bigcap_{\epsilon > 0} \partial_\epsilon f(x).$$

However $\delta^*(y|\partial_\epsilon f(x)) = I_{\partial_\epsilon f(x)}^*(y)$ does not necessarily decrease to $\delta^*(y|\partial f(x)) = I_{\partial f(x)}^*(y)$ as ϵ decreases to zero. The discrepancy corresponds to the discrepancy between $f'(x; y)$ and $\delta^*(y|\partial f(x)) = I_{\partial f(x)}^*(y)$ and is due to the fact that f is not necessarily closed (see Proposition 51.16) as shown by the following result proven in Rockafellar [138] (Theorem 23.6).

Proposition 51.33. *Let f be a closed and proper convex function, and let $x \in \mathbb{R}^n$ such that $f(x)$ is finite. Then*

$$f'(x; y) = \lim_{\epsilon \downarrow 0} \delta^*(y|\partial_\epsilon f(x)) = \lim_{\epsilon \downarrow 0} I_{\partial_\epsilon f(x)}^*(y) \quad \text{for all } y \in \mathbb{R}^n.$$

The theory of convex functions is rich and we have only given a sample of some of the most significant results that are relevant to optimization theory. There are a few more results regarding the minimum of convex functions that are particularly important due to their applications to optimization theory.

51.5 The Minimum of a Proper Convex Function

Let h be a proper convex function on \mathbb{R}^n . The general problem is to study the minimum of h over a nonempty convex set C in \mathbb{R}^n , possibly defined by a set of inequality and equality constraints. We already observed that minimizing h over C is equivalent to minimizing the proper convex function f given by

$$f(x) = h(x) + I_C(x) = \begin{cases} h(x) & \text{if } x \in C \\ +\infty & \text{if } x \notin C. \end{cases}$$

Therefore it makes sense to begin by considering the problem of minimizing a proper convex function f over \mathbb{R}^n . Of course, minimizing over \mathbb{R}^n is equivalent to minimizing over $\text{dom}(f)$.

Definition 51.18. Let f be a proper convex function on \mathbb{R}^n . We denote by $\inf f$ the quantity

$$\inf f = \inf_{x \in \text{dom}(f)} f(x).$$

This is the minimum of the function f over \mathbb{R}^n (it may be equal to $-\infty$).

For every $\alpha \in \mathbb{R}$, we have the sublevel set

$$\text{sublev}_\alpha(f) = \{x \in \mathbb{R}^n \mid f(x) \leq \alpha\}.$$

By Proposition 51.2, we know that the sublevel sets $\text{sublev}_\alpha(f)$ are convex and that

$$\text{dom}(f) = \bigcup_{\alpha \in \mathbb{R}} \text{sublev}_\alpha(f).$$

Observe that $\text{sublev}_\alpha(f) = \emptyset$ if $\alpha < \inf f$. If $\inf f > -\infty$, then for $\alpha = \inf f$, the sublevel set $\text{sublev}_\alpha(f)$ consists of the set of vectors where f achieves its minimum.

Definition 51.19. Let f be a proper convex function on \mathbb{R}^n . If $\inf f > -\infty$, then the sublevel set $\text{sublev}_{\inf f}(f)$ is called the *minimum set* of f (this set may be empty). See Figure 51.24.

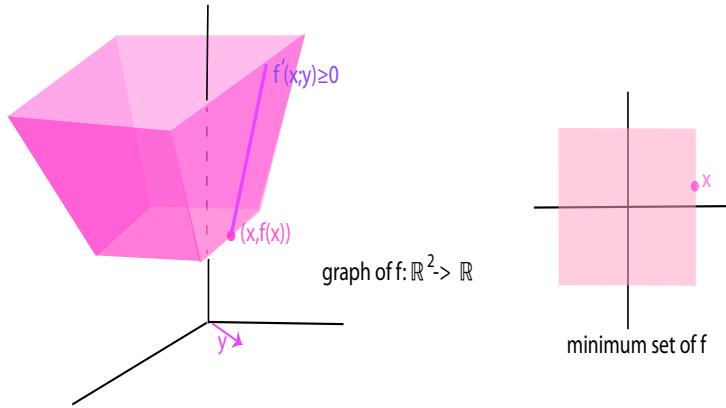

Figure 51.24: Let f be the proper convex function whose graph is the surface of the upward facing pink trough. The minimum set of f is the light pink square of \mathbb{R}^2 which maps to the bottom surface of the trough in \mathbb{R}^3 . For any x in the minimum set, $f'(x; y) \geq 0$, a fact substantiated by Proposition 51.34.

It is important to determine whether the minimum set is empty or nonempty, or whether it contains a single point. As we noted in Theorem 40.13(2), if f is strictly convex then the minimum set contains at most one point.

In any case, we know from Proposition 51.2 and Proposition 51.3 that the minimum set of f is convex, and closed iff f is closed.

Subdifferentials provide the first criterion for deciding whether a vector $x \in \mathbb{R}^n$ belongs to the minimum set of f . Indeed, the very definition of a subgradient says that $x \in \mathbb{R}^n$ belongs to the minimum set of f iff $0 \in \partial f(x)$. Using Proposition 51.16, we obtain the following result.

Proposition 51.34. *Let f be a proper convex function over \mathbb{R}^n . A vector $x \in \mathbb{R}^n$ belongs to the minimum set of f iff*

$$0 \in \partial f(x)$$

iff $f(x)$ is finite and

$$f'(x; y) \geq 0 \quad \text{for all } y \in \mathbb{R}^n.$$

Of course, if f is differentiable at x , then $\partial f(x) = \{\nabla f_x\}$, and we obtain the well-known condition $\nabla f_x = 0$.

There are many ways of expressing the conditions of Proposition 51.34, and the minimum set of f can even be characterized in terms of the conjugate function f^* . The notion of direction of recession plays a key role.

Definition 51.20. Let $f: \mathbb{R}^n \rightarrow \mathbb{R} \cup \{+\infty\}$ be any function. A *direction of recession* of f is any non-zero vector $u \in \mathbb{R}^n$ such that for every $x \in \text{dom}(f)$, the function $\lambda \mapsto f(x + \lambda u)$ is nonincreasing (this means that for all $\lambda_1, \lambda_2 \in \mathbb{R}$, if $\lambda_1 < \lambda_2$, then $x + \lambda_1 u \in \text{dom}(f)$, $x + \lambda_2 u \in \text{dom}(f)$, and $f(x + \lambda_2 u) \leq f(x + \lambda_1 u)$).

Example 51.12. Consider the function $f: \mathbb{R}^2 \rightarrow \mathbb{R}$ given by $f(x, y) = 2x + y^2$. Since

$$f(x + \lambda u, y + \lambda v) = 2(x + \lambda u) + (y + \lambda v)^2 = 2x + y^2 + 2(u + yv)\lambda + v^2\lambda^2,$$

if $v \neq 0$, we see that the above quadratic function of λ increases for $\lambda \geq -(u + yv)/v^2$. If $v = 0$, then the function $\lambda \mapsto 2x + y^2 + 2u\lambda$ decreases to $-\infty$ when λ goes to $+\infty$ if $u < 0$, so all vectors $(-u, 0)$ with $u > 0$ are directions of recession. See Figure 51.25.

The function $f(x, y) = 2x + x^2 + y^2$ does not have any direction of recession, because

$$f(x + \lambda u, y + \lambda v) = 2x + x^2 + y^2 + 2(u + ux + yv)\lambda + (u^2 + v^2)\lambda^2,$$

and since $(u, v) \neq (0, 0)$, we have $u^2 + v^2 > 0$, so as a function of λ , the above quadratic function increases for $\lambda \geq -(u + ux + yv)/(u^2 + v^2)$. See Figure 51.25.

In fact, the above example is typical. For any symmetric positive definite $n \times n$ matrix A and any vector $b \in \mathbb{R}^n$, the quadratic strictly convex function q given by $q(x) = x^\top Ax + b^\top x$ has no directions of recession. For any $u \in \mathbb{R}^n$, with $u \neq 0$, we have

$$\begin{aligned} q(x + \lambda u) &= (x + \lambda u)^\top A(x + \lambda u) + b^\top(x + \lambda u) \\ &= x^\top Ax + b^\top x + (2x^\top Au + b^\top u)\lambda + (u^\top Au)\lambda^2. \end{aligned}$$

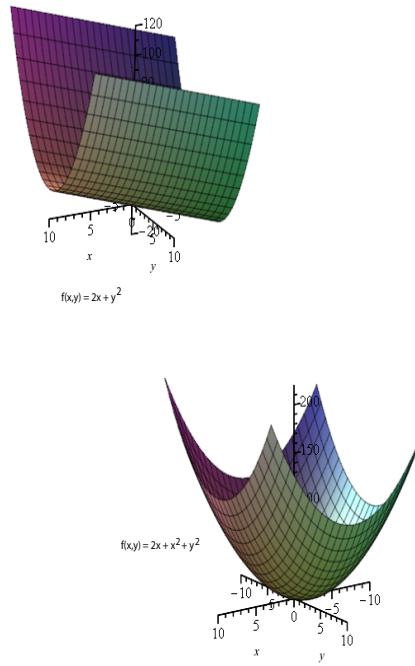

Figure 51.25: The graphs of the two functions discussed in Example 51.12. The graph of $f(x, y) = 2x + y^2$ slopes "downward" along the negative x -axis, reflecting the fact that $(-u, 0)$ is a direction of recession.

Since $u \neq 0$ and A is SPD, we have $u^\top A u > 0$, and the above quadratic function increases for $\lambda \geq -(2x^\top A u + b^\top u)/(2u^\top A u)$.

The above fact yields an important trick of convex optimization. If f is any proper closed and convex function, then for any quadratic strictly convex function q , the function $h = f + q$ is a proper and closed strictly convex function that has a minimum which is attained for a *unique* vector. This trick is at the core of the method of augmented Lagrangians, and in particular ADMM. Surprisingly, a rigorous proof requires the deep theorem below.

One should be careful not to conclude hastily that if a convex function is proper and closed, then $\text{dom}(f)$ and $\text{Im}(f)$ are also closed. Also, a closed and proper convex function may not attain its minimum. For example, the function $f: \mathbb{R} \rightarrow \mathbb{R} \cup \{+\infty\}$ given by

$$f(x) = \begin{cases} \frac{1}{x} & \text{if } x > 0 \\ +\infty & \text{if } x \leq 0 \end{cases}$$

is a proper, closed and convex function, but $\text{dom}(f) = (0, +\infty)$ and $\text{Im}(f) = (0, +\infty)$. Note that $\inf f = 0$ is not attained. The problem is that f has 1 has a direction of recession as evidenced by the graph provided in Figure 51.26.

The following theorem is proven in Rockafellar [138] (Theorem 27.1).

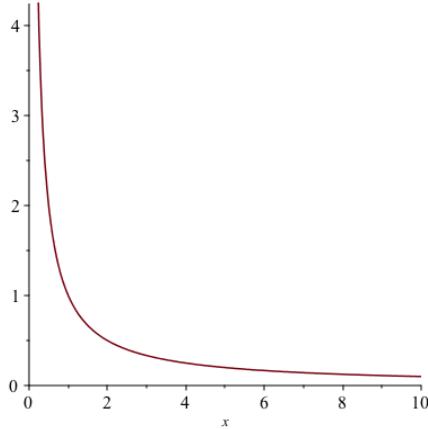

Figure 51.26: The graph of the partial function $f(x) = \frac{1}{x}$ for $x > 0$. The graph of this function decreases along the x -axis since 1 is a direction of recession.

Theorem 51.35. *Let f be a proper and closed convex function over \mathbb{R}^n . The following statements hold:*

- (1) *We have $\inf f = -f^*(0)$. Thus f is bounded below iff $0 \in \text{dom}(f^*)$.*
- (2) *The minimum set of f is equal to $\partial f^*(0)$. Thus the infimum of f is attained (which means that there is some $x \in \mathbb{R}^n$ such that $f(x) = \inf f$) iff f^* is subdifferentiable at 0. This condition holds in particular when $0 \in \text{relint}(\text{dom}(f^*))$. Moreover, $0 \in \text{relint}(\text{dom}(f^*))$ iff every direction of recession of f is a direction in which f is constant.*
- (3) *For the infimum of f to be finite but unattained, it is necessary and sufficient that $f^*(0)$ be finite and $(f^*)'(0; y) = -\infty$ for some $y \in \mathbb{R}^n$.*
- (4) *The minimum set of f is a nonempty bounded set iff $0 \in \text{int}(\text{dom}(f^*))$. This condition holds iff f has no directions of recession.*
- (5) *The minimum set of f consists of a unique vector x iff f^* is differentiable at x and $x = \nabla f_0^*$.*
- (6) *For each $\alpha \in \mathbb{R}$, the support function of $\text{sublev}_\alpha(f)$ is the closure of the positively homogeneous convex function generated by $f^* + \alpha$. If f is bounded below, then the support function of the minimum set of f is the closure of the directional derivative map $y \mapsto (f^*)'(0; y)$.*

In view of the importance of Theorem 51.35(4), we state this property as the following corollary.

Corollary 51.36. *Let f be a closed proper convex function on \mathbb{R}^n . Then the minimal set of f is a non-empty bounded set iff f has no directions of recession. In particular, if f has no directions of recession, then the minimum $\inf f$ of f is finite and attained for some $x \in \mathbb{R}^n$.*

Theorem 51.14 implies the following result which is very important for the design of optimization procedures.

Proposition 51.37. *Let f be a proper and closed convex function over \mathbb{R}^n . The function h given by $h(x) = f(x) + q(x)$ obtained by adding any strictly convex quadratic function q of the form $q(x) = x^\top Ax + b^\top x$ (where A is symmetric positive definite) is a proper closed strictly convex function such that $\inf h$ is finite, and there is a unique $x^* \in \mathbb{R}^n$ such that h attains its minimum in x^* (that is, $h(x^*) = \inf h$).*

Proof. By Theorem 51.14 there is some affine form φ given by $\varphi(x) = c^\top x + \alpha$ (with $\alpha \in \mathbb{R}$) such that $f(x) \geq \varphi(x)$ for all $x \in \mathbb{R}^n$. Then we have

$$h(x) = f(x) + q(x) \geq x^\top Ax + (b^\top + c^\top)x + \alpha \quad \text{for all } x \in \mathbb{R}^n.$$

Since A is symmetric positive definite, by Example 51.12, the quadratic function Q given by $Q(x) = x^\top Ax + (b^\top + c^\top)x + \alpha$ has no directions of recession. Since $h(x) \geq Q(x)$ for all $x \in \mathbb{R}^n$, we claim that h has no directions of recession. Otherwise, there would be some nonzero vector u , such that the function $\lambda \mapsto h(x + \lambda u)$ is nonincreasing for all $x \in \text{dom}(h)$, so $h(x + \lambda u) \leq \beta$ for some β for all λ . But we showed that for λ large enough, the function $\lambda \mapsto Q(x + \lambda u)$ increases like λ^2 , so for λ large enough, we will have $Q(x + \lambda u) > \beta$, contradicting the fact that h majorizes Q . By Corollary 51.36, h has a finite minimum x^* which is attained.

If f and g are proper convex functions and if g is strictly convex, then $f + g$ is a proper function. For all $x, y \in \mathbb{R}^n$, for any λ such that $0 < \lambda < 1$, since f is convex and g is strictly convex, we have

$$\begin{aligned} f((1 - \lambda)x + \lambda y) &\leq (1 - \lambda)f(x) + \lambda f(y) \\ g((1 - \lambda)x + \lambda y) &< (1 - \lambda)g(x) + \lambda g(y), \end{aligned}$$

so we deduce that

$$f((1 - \lambda)x + \lambda y) + g((1 - \lambda)x + \lambda y) < ((1 - \lambda)(f(x) + g(x)) + \lambda(f(x) + g(x))),$$

which shows that $f + g$ is strictly convex. Then, as $f + g$ is strictly convex, it has a unique minimum at x^* . \square

We now come back to the problem of minimizing a proper convex function h over a nonempty convex subset C . Here is a nice characterization.

Proposition 51.38. *Let h be a proper convex function on \mathbb{R}^n , and let C be a nonempty convex subset of \mathbb{R}^n .*

- (1) For any $x \in \mathbb{R}^n$, if there is some $y \in \partial h(x)$ such that $-y \in N_C(x)$, that is, $-y$ is normal to C at x , then h attains its minimum on C at x .
- (2) If $\text{relint}(\text{dom}(h)) \cap \text{relint}(C) \neq \emptyset$, then the converse of (1) holds. This means that if h attains its minimum on C at x , then there is some $y \in \partial h(x)$ such that $-y \in N_C(x)$.

Proposition 51.38 is proven in Rockafellar [138] (Theorem 27.4). The proof is actually quite simple.

Proof. (1) By Proposition 51.34, h attains its minimum on C at x iff

$$0 \in \partial(h + I_C)(x).$$

By Proposition 51.23, since

$$\partial(h + I_C)(x) \subseteq \partial h(x) + \partial I_C(x),$$

if $0 \in \partial h(x) + \partial I_C(x)$, then h attains its minimum on C at x . But we saw in Section 51.2 that $\partial I_C(x) = N_C(x)$, the normal cone to C at x . Then the condition $0 \in \partial h(x) + \partial I_C(x)$ says that there is some $y \in \partial h(x)$ such that $y + z = 0$ for some $z \in N_C(x)$, and this is equivalent to $-y \in N_C(x)$.

(2) By definition of I_C , the condition $\text{relint}(\text{dom}(h)) \cap \text{relint}(C) \neq \emptyset$ is the hypothesis of Proposition 51.23 to have

$$\partial(h + I_C)(x) = \partial h(x) + \partial I_C(x),$$

so we deduce that $y \in \partial(h + I_C)(x)$, and By Proposition 51.34, h attains its minimum on C at x . \square

Remark: A *polyhedral function* is a convex function whose epigraph is a polyhedron. It is easy to see that Proposition 51.38(2) also holds in the following cases

- (1) C is a \mathcal{H} -polyhedron and $\text{relint}(\text{dom}(h)) \cap C \neq \emptyset$
- (2) h is polyhedral and $\text{dom}(h) \cap \text{relint}(C) \neq \emptyset$.
- (3) Both h and C are polyhedral, and $\text{dom}(h) \cap C \neq \emptyset$.

51.6 Generalization of the Lagrangian Framework

Essentially all the results presented in Section 50.3, Section 50.7, Section 50.8, and Section 50.9 about Lagrangians and Lagrangian duality generalize to programs involving a proper and convex objective function J , proper and convex inequality constraints, and affine equality constraints. The extra generality is that it is no longer assumed that these functions are

differentiable. This theory is thoroughly discussed in Part VI, Section 28, of Rockafellar [138], for programs called ordinary convex programs. We do not have the space to even sketch this theory but we will spell out some of the key results.

We will be dealing with programs consisting of an objective function $J: \mathbb{R}^n \rightarrow \mathbb{R} \cup \{+\infty\}$ which is convex and proper, subject to $m \geq 0$ inequality constraints $\varphi_i(v) \leq 0$, and $p \geq 0$ affine equality constraints $\psi_j(v) = 0$. The constraint functions φ_i are also convex and proper, and we assume that

$$\text{relint}(\text{dom}(J)) \subseteq \text{relint}(\text{dom}(\varphi_i)), \quad \text{dom}(J) \subseteq \text{dom}(\varphi_i), \quad i = 1, \dots, m.$$

Such programs are *called ordinary convex programs*. Let

$$U = \text{dom}(J) \cap \{v \in \mathbb{R}^n \mid \varphi_i(v) \leq 0, \psi_j(v) = 0, 1 \leq i \leq m, 1 \leq j \leq p\},$$

be the set of *feasible solutions*. We are seeking elements in $u \in U$ that minimize J over U .

A generalized version of Theorem 50.18 holds under the above hypotheses on J and the constraints φ_i and ψ_j , except that in the KKT conditions, the equation involving gradients must be replaced by the following condition involving subdifferentials:

$$0 \in \partial \left(J + \sum_{i=1}^m \lambda_i \varphi_i + \sum_{j=1}^p \mu_j \psi_j \right)(u),$$

with $\lambda_i \geq 0$ for $i = 1, \dots, m$ and $\mu_j \in \mathbb{R}$ for $j = 1, \dots, p$ (where $u \in U$ and J attains its minimum at u).

The *Lagrangian* $L(v, \lambda, \nu)$ of our problem is defined as follows: Let

$$E_m = \{x \in \mathbb{R}^{m+p} \mid x_i \geq 0, 1 \leq i \leq m\}.$$

Then

$$L(v, \lambda, \mu) = \begin{cases} J(v) + \sum_{i=1}^m \lambda_i \varphi_i(v) + \sum_{j=1}^p \mu_j \psi_j(v) & \text{if } (\lambda, \mu) \in E_m, v \in \text{dom}(J) \\ -\infty & \text{if } (\lambda, \mu) \notin E_m, v \in \text{dom}(J) \\ +\infty & \text{if } v \notin \text{dom}(J). \end{cases}$$

For *fixed values* $(\lambda, \mu) \in \mathbb{R}_+^m \times \mathbb{R}^p$, we also define the function $h: \mathbb{R}^n \rightarrow \mathbb{R} \cup \{+\infty\}$ given by

$$h(x) = J(x) + \sum_{i=1}^m \lambda_i \varphi_i(x) + \sum_{j=1}^p \mu_j \psi_j(x),$$

whose effective domain is $\text{dom}(J)$ (since we are assuming that $\text{dom}(J) \subseteq \text{dom}(\varphi_i)$, $i = 1, \dots, m$). Thus $h(x) = L(x, \lambda, \mu)$, but h is a *function only of x*, so we denote it differently to avoid confusion (also, technically, $L(x, \lambda, \mu)$ may take the value $-\infty$, but h does not).

Since J and the φ_i are proper convex functions and the ψ_j are affine, the function h is a proper convex function.

A proof of a generalized version of Theorem 50.18 can be obtained by putting together Theorem 28.1, Theorem 28.2, and Theorem 28.3, in Rockafellar [138]. For the sake of completeness, we state these theorems. Here is Theorem 28.1.

Theorem 51.39. (*Theorem 28.1, Rockafellar*) Let (P) be an ordinary convex program. Let $(\lambda, \mu) \in \mathbb{R}_+^m \times \mathbb{R}^p$ be Lagrange multipliers such that the infimum of the function $h = J + \sum_{i=1}^m \lambda_i \varphi_i + \sum_{j=1}^p \mu_j \psi_j$ is finite and equal to the optimal value of J over U . Let D be the minimal set of h over \mathbb{R}^n , and let $I = \{i \in \{1, \dots, m\} \mid \lambda_i = 0\}$. If D_0 is the subset of D consisting of vectors x such that

$$\begin{aligned}\varphi_i(x) &\leq 0 && \text{for all } i \in I \\ \varphi_i(x) &= 0 && \text{for all } i \notin I \\ \psi_j(x) &= 0 && \text{for all } j = 1, \dots, p,\end{aligned}$$

then D_0 is the set of minimizers of (P) over U .

And now here is Theorem 28.2.

Theorem 51.40. (*Theorem 28.2, Rockafellar*) Let (P) be an ordinary convex program, and let $I \subseteq \{1, \dots, m\}$ be the subset of indices of inequality constraints that are not affine. Assume that the optimal value of (P) is finite, and that (P) has at least one feasible solution $x \in \text{relint}(\text{dom}(J))$ such that

$$\varphi_i(x) < 0 \quad \text{for all } i \in I.$$

Then there exist some Lagrange multipliers $(\lambda, \mu) \in \mathbb{R}_+^m \times \mathbb{R}^p$ (not necessarily unique) such that

- (a) The infimum of the function $h = J + \sum_{i=1}^m \lambda_i \varphi_i + \sum_{j=1}^p \mu_j \psi_j$ is finite and equal to the optimal value of J over U .

The hypotheses of Theorem 51.40 are qualification conditions on the constraints, essentially Slater's conditions from Definition 50.6.

Definition 51.21. Let (P) be an ordinary convex program, and let $I \subseteq \{1, \dots, m\}$ be the subset of indices of inequality constraints that are not affine. The constraints are *qualified* if there is a feasible solution $x \in \text{relint}(\text{dom}(J))$ such that

$$\varphi_i(x) < 0 \quad \text{for all } i \in I.$$

Finally, here is Theorem 28.3 from Rockafellar [138].

Theorem 51.41. (*Theorem 28.3, Rockafellar*) Let (P) be an ordinary convex program. If $x \in \mathbb{R}^n$ and $(\lambda, \mu) \in \mathbb{R}_+^m \times \mathbb{R}^p$, then (λ, μ) and x have the property that

(a) The infimum of the function $h = J + \sum_{i=1}^m \lambda_i \varphi_i + \sum_{j=1}^p \mu_j \psi_j$ is finite and equal to the optimal value of J over U , and

(b) The vector x is an optimal solution of (P) (so $x \in U$),

iff (x, λ, μ) is a saddle point of the Lagrangian $L(x, \lambda, \mu)$ of (P) .

Moreover, this condition holds iff the following KKT conditions hold:

(1) $\lambda \in \mathbb{R}_+^m$, $\varphi_i(x) \leq 0$, and $\lambda_i \varphi_i(x) = 0$ for $i = 1, \dots, m$.

(2) $\psi_j(x) = 0$ for $j = 1, \dots, p$.

(3) $0 \in \partial J(x) + \sum_{i=1}^m \partial \lambda_i \varphi_i(x) + \sum_{j=1}^p \partial \mu_j \psi_j(x)$.

Observe that by Theorem 51.40, if the optimal value of (P) is finite and if the constraints are qualified, then Condition (a) of Theorem 51.41 holds for (λ, μ) . As a consequence we obtain the following corollary of Theorem 51.41 attributed to Kuhn and Tucker, which is one of the main results of the theory. It is a generalized version of Theorem 50.18.

Theorem 51.42. (Theorem 28.3.1, Rockafellar) Let (P) be an ordinary convex program satisfying the hypothesis of Theorem 51.40, which means that the optimal value of (P) is finite, and that the constraints are qualified. In order that a vector $x \in \mathbb{R}^n$ be an optimal solution to (P) , it is necessary and sufficient that there exist Lagrange multipliers $(\lambda, \mu) \in \mathbb{R}_+^m \times \mathbb{R}^p$ such that (x, λ, μ) is a saddle point of $L(x, \lambda, \mu)$. Equivalently, x is an optimal solution of (P) if and only if there exist Lagrange multipliers $(\lambda, \mu) \in \mathbb{R}_+^m \times \mathbb{R}^p$, which, together with x , satisfy the KKT conditions from Theorem 51.41.

Theorem 51.42 has to do with the existence of an optimal solution for (P) , but it does not say anything about the optimal value of (P) . To establish such a result, we need the notion of dual function.

The dual function G is defined by

$$G(\lambda, \mu) = \inf_{v \in \mathbb{R}^n} L(v, \lambda, \mu).$$

It is a concave function (so $-G$ is convex) which may take the values $\pm\infty$. Note that maximizing G , which is equivalent to minimizing $-G$, runs into troubles if $G(\lambda, \mu) = +\infty$ for some λ, μ , but that $G(\lambda, \mu) = -\infty$ does not cause a problem. At first glance, this seems counterintuitive, but remember that G is *concave*, not *convex*. It is $-G$ that is convex, and $-\infty$ and $+\infty$ get flipped.

Then a generalized and stronger version of Theorem 50.19(2) also holds. A proof can be obtained by putting together Corollary 28.3.1, Theorem 28.4, and Corollary 28.4.1, in Rockafellar [138]. For the sake of completeness, we state the following results from Rockafellar [138].

Theorem 51.43. (*Theorem 28.4, Rockafellar*) Let (P) be an ordinary convex program with Lagrangian $L(x, \lambda, \mu)$. If the Lagrange multipliers $(\lambda^*, \mu^*) \in \mathbb{R}_+^m \times \mathbb{R}^p$ and the vector $x^* \in \mathbb{R}^n$ have the property that

(a) The infimum of the function $h = J + \sum_{i=1}^m \lambda_i^* \varphi_i + \sum_{j=1}^p \mu_j^* \psi_j$ is finite and equal to the optimal value of J over U , and

(b) The vector x^* is an optimal solution of (P) (so $x^* \in U$),

then the saddle value $L(x^*, \lambda^*, \mu^*)$ is the optimal value $J(x^*)$ of (P) .

More generally, the Lagrange multipliers $(\lambda^*, \mu^*) \in \mathbb{R}_+^m \times \mathbb{R}^p$ have Property (a) iff

$$-\infty < \inf_x L(x, \lambda^*, \mu^*) \leq \sup_{\lambda, \mu} \inf_x L(x, \lambda, \mu) = \inf_x \sup_{\lambda, \mu} L(x, \lambda, \mu),$$

in which case, the common value of the extremum value is the optimal value of (P) . In particular, if x^* is an optimal solution for (P) , then $\sup_{\lambda, \mu} G(\lambda, \mu) = L(x^*, \lambda^*, \mu^*) = J(x^*)$ (zero duality gap).

Observe that Theorem 51.43 gives sufficient Conditions (a) and (b) for the duality gap to be zero. In view of Theorem 51.41, these conditions are equivalent to the fact that (x^*, λ^*, μ^*) is a saddle point of L , or equivalently that the KKT conditions hold.

Again, by Theorem 51.40, if the optimal value of (P) is finite and if the constraints are qualified, then Condition (a) of Theorem 51.43 holds for (λ, μ) . Then the following corollary of Theorem 51.43 holds.

Theorem 51.44. (*Theorem 28.4.1, Rockafellar*) Let (P) be an ordinary convex program satisfying the hypothesis of Theorem 51.40, which means that the optimal value of (P) is finite, and that the constraints are qualified. The Lagrange multipliers $(\lambda, \mu) \in \mathbb{R}_+^m \times \mathbb{R}^p$ that have the property that the infimum of the function $h = J + \sum_{i=1}^m \lambda_i \varphi_i + \sum_{j=1}^p \mu_j \psi_j$ is finite and equal to the optimal value of J over U are exactly the vectors where the dual function G attains its supremum over \mathbb{R}^n .

Theorem 51.44 is a generalized and stronger version of Theorem 50.19(2). Part (1) of Theorem 50.19 requires J and the φ_i to be differentiable, so it does not generalize.

More results can be shown about ordinary convex programs, and another class of programs called *generalized convex programs*. However, we do not need such results for our purposes, in particular to discuss the ADMM method. The interested reader is referred to Rockafellar [138] (Part VI, Sections 28 and 29).

51.7 Summary

The main concepts and results of this chapter are listed below:

- Extended real-valued functions.

- Epigraph ($\text{epi}(f)$).
- Convex and concave (extended real-valued) functions.
- Effective domain ($\text{dom}(f)$).
- Proper and improper convex functions.
- Sublevel sets.
- Lower semi-continuous functions.
- Lower semi-continuous hull; closure of a convex function.
- Relative interior ($\text{relint}(C)$).
- Indicator function.
- Lipschitz condition.
- Affine form, affine hyperplane.
- Half spaces.
- Supporting hyperplane.
- Normal cone at a .
- Subgradient, subgradient inequality, subdifferential.
- Minkowski's supporting hyperplane theorem.
- One-sided directional derivative.
- Support function.
- ReLU function.
- ϵ -subgradient.
- Minimum set of a convex function.
- Direction of recession.
- Ordinary convex programs.
- Set of feasible solutions.
- Lagrangian.

- Saddle point.
- KKT conditions.
- Qualified constraints.
- Duality gap.

51.8 Problems

Problem 51.1. Prove Proposition 51.1.

Problem 51.2. Prove Proposition 51.2.

Problem 51.3. Prove Proposition 51.3.

Problem 51.4. Prove that the convex function defined in Example 51.4 has the property that the limit along any line segment from $(0, 0)$ to a point in the open right half-plane is 0.

Problem 51.5. Check that the normal cone to C at a is a convex cone.

Problem 51.6. Prove that $\partial f(x)$ is closed and convex.

Problem 51.7. For Example 51.6, with $f(x) = \|x\|_\infty$, prove that $\partial f(0)$ is the polyhedron

$$\partial f(0) = \text{conv}\{\pm e_1, \dots, \pm e_n\}.$$

Problem 51.8. For Example 51.7, with

$$f(x) = \begin{cases} -(1 - |x|^2)^{1/2} & \text{if } |x| \leq 1 \\ +\infty & \text{otherwise.} \end{cases}$$

prove that f is subdifferentiable (in fact differentiable) at x when $|x| < 1$, but $\partial f(x) = \emptyset$ when $|x| \geq 1$, even though $x \in \text{dom}(f)$ for $|x| = 1$

Problem 51.9. Prove Proposition 51.15.

Problem 51.10. Prove that as a convex function of u , the effective domain of the function $u \mapsto f'(x; u)$ is the convex cone generated by $\text{dom}(f) - x$.

Problem 51.11. Prove Proposition 51.28.

Problem 51.12. Prove Proposition 51.33.

Problem 51.13. Prove that Proposition 51.38(2) also holds in the following cases:

- (1) C is a \mathcal{H} -polyhedron and $\text{relint}(\text{dom}(h)) \cap C \neq \emptyset$
- (2) h is polyhedral and $\text{dom}(h) \cap \text{relint}(C) \neq \emptyset$.
- (3) Both h and C are polyhedral, and $\text{dom}(h) \cap C \neq \emptyset$.

Chapter 52

Dual Ascent Methods; ADMM

This chapter is devoted to the presentation of one of the best methods known at the present for solving optimization problems involving equality constraints. In fact, this method can also handle more general constraints, namely, membership in a convex set. It can also be used to solve a range of problems arising in machine learning including *lasso minimization*, *elastic net regression*, *support vector machine (SVM)*, and ν -*SV regression*. In order to obtain a good understanding of this method, called the *alternating direction method of multipliers*, for short *ADMM*, we review two precursors of ADMM, the *dual ascent method* and the *method of multipliers*.

ADMM is not a new method. In fact, it was developed in the 1970's. It has been revived as a very effective method to solve problems in statistical and machine learning dealing with very large data because it is well suited to distributed (convex) optimization. An extensive presentation of ADMM, its variants, and its applications, is given in the excellent paper by Boyd, Parikh, Chu, Peleato and Eckstein [28]. This paper is essentially a book on the topic of ADMM, and our exposition is deeply inspired by it.

In this chapter, we consider the problem of minimizing a convex function J (not necessarily differentiable) under the equality constraints $Ax = b$. In Section 52.1 we discuss the dual ascent method. It is essentially gradient descent applied to the dual function G , but since G is maximized, gradient descent becomes gradient ascent.

In order to make the minimization step of the dual ascent method more robust, one can use the trick of adding the penalty term $(\rho/2) \|Au - b\|_2^2$ to the Lagrangian. We obtain the *augmented Lagrangian*

$$L_\rho(u, \lambda) = J(u) + \lambda^\top(Au - b) + (\rho/2) \|Au - b\|_2^2,$$

with $\lambda \in \mathbb{R}^m$, and where $\rho > 0$ is called the *penalty parameter*. We obtain the minimization Problem (P_ρ) ,

$$\begin{aligned} & \text{minimize} && J(u) + (\rho/2) \|Au - b\|_2^2 \\ & \text{subject to} && Au = b, \end{aligned}$$

which is equivalent to the original problem.

The benefit of adding the penalty term $(\rho/2) \|Au - b\|_2^2$ is that by Proposition 51.37, Problem (P_ρ) has a unique optimal solution under mild conditions on A . Dual ascent applied to the dual of (P_ρ) is called the *method of multipliers* and is discussed in Section 52.2.

The alternating direction method of multipliers, for short ADMM, combines the decomposability of dual ascent with the superior convergence properties of the method of multipliers. The idea is to split the function J into two independent parts, as $J(x, z) = f(x) + g(z)$, and to consider the Minimization Problem (P_{admm}) ,

$$\begin{aligned} &\text{minimize} \quad f(x) + g(z) \\ &\text{subject to} \quad Ax + Bz = c, \end{aligned}$$

for some $p \times n$ matrix A , some $p \times m$ matrix B , and with $x \in \mathbb{R}^n$, $z \in \mathbb{R}^m$, and $c \in \mathbb{R}^p$. We also assume that f and g are convex. Further conditions will be added later.

As in the method of multipliers, we form the augmented Lagrangian

$$L_\rho(x, z, \lambda) = f(x) + g(z) + \lambda^\top(Ax + Bz - c) + (\rho/2) \|Ax + Bz - c\|_2^2,$$

with $\lambda \in \mathbb{R}^p$ and for some $\rho > 0$. The major difference with the method of multipliers is that instead of performing a minimization step jointly over x and z , ADMM *first performs an x -minimization step and then a z -minimization step*. Thus x and z are updated in an alternating or sequential fashion, which accounts for the term *alternating direction*. Because the Lagrangian is augmented, some mild conditions on A and B imply that these minimization steps are guaranteed to terminate. ADMM is presented in Section 52.3.

In Section 52.4 we prove the convergence of ADMM under the following assumptions:

- (1) The functions $f: \mathbb{R} \rightarrow \mathbb{R} \cup \{+\infty\}$ and $g: \mathbb{R} \rightarrow \mathbb{R} \cup \{+\infty\}$ are proper and closed convex functions (see Section 51.1) such that $\text{relint}(\text{dom}(f)) \cap \text{relint}(\text{dom}(g)) \neq \emptyset$.
- (2) The $n \times n$ matrix $A^\top A$ is invertible and the $m \times m$ matrix $B^\top B$ is invertible. Equivalently, the $p \times n$ matrix A has rank n and the $p \times m$ matrix has rank m .
- (3) The unaugmented Lagrangian $L_0(x, z, \lambda) = f(x) + g(z) + \lambda^\top(Ax + Bz - c)$ has a saddle point, which means there exists x^*, z^*, λ^* (not necessarily unique) such that

$$L_0(x^*, z^*, \lambda) \leq L_0(x^*, z^*, \lambda^*) \leq L_0(x, z, \lambda^*)$$

for all x, z, λ .

By Theorem 51.41, Assumption (3) is equivalent to the fact that the KKT equations are satisfied by some triple (x^*, z^*, λ^*) , namely

$$Ax^* + Bz^* - c = 0 \tag{*}$$

and

$$0 \in \partial f(x^*) + \partial g(z^*) + A^\top \lambda^* + B^\top \lambda^*, \quad (\dagger)$$

Assumption (3) is also equivalent to Conditions (a) and (b) of Theorem 51.41. In particular, our program has an optimal solution (x^*, z^*) . By Theorem 51.43, λ^* is maximizer of the dual function $G(\lambda) = \inf_{x,z} L_0(x, z, \lambda)$ and strong duality holds, that is, $G(\lambda^*) = f(x^*) + g(z^*)$ (the duality gap is zero).

We will show after the proof of Theorem 52.1 that Assumption (2) is actually implied by Assumption (3). This allows us to prove a convergence result stronger than the convergence result proven in Boyd et al. [28] (under the exact same assumptions (1) and (3)). In particular, we prove that *all* of the sequences (x^k) , (z^k) , and (λ^k) converge to optimal solutions (\tilde{x}, \tilde{z}) , and $\tilde{\lambda}$. The core of our proof is due to Boyd et al. [28], but there are new steps because we have the stronger hypothesis (2).

In Section 52.5, we discuss stopping criteria.

In Section 52.6 we present some applications of ADMM, in particular, minimization of a proper closed convex function f over a closed convex set C in \mathbb{R}^n and quadratic programming. The second example provides one of the best methods for solving quadratic problems, including the SVM problems discussed in Chapter 54, the elastic net method in Section 55.6, and ν -SV regression in Chapter 56.

Section 52.8 gives applications of ADMM to ℓ^1 -norm problems, in particular, lasso regularization, which plays an important role in machine learning.

52.1 Dual Ascent

Our goal is to solve the [minimization problem](#), Problem (P),

$$\begin{aligned} & \text{minimize } J(u) \\ & \text{subject to } Au = b, \end{aligned}$$

with [affine equality constraints](#) (with A an $m \times n$ matrix and $b \in \mathbb{R}^m$). The [Lagrangian](#) $L(u, \lambda)$ of Problem (P) is given by

$$L(u, \lambda) = J(u) + \lambda^\top (Au - b).$$

with $\lambda \in \mathbb{R}^m$. From Proposition 50.20, the dual function $G(\lambda) = \inf_{u \in \mathbb{R}^n} L(u, \lambda)$ is given by

$$G(\lambda) = \begin{cases} -b^\top \lambda - J^*(-A^\top \lambda) & \text{if } -A^\top \lambda \in \text{dom}(J^*), \\ -\infty & \text{otherwise,} \end{cases}$$

for all $\lambda \in \mathbb{R}^m$, where J^* is the conjugate of J . Recall that by Definition 50.11, the *conjugate* f^* of a function $f: U \rightarrow \mathbb{R}$ defined on a subset U of \mathbb{R}^n is the partial function $f^*: \mathbb{R}^n \rightarrow \mathbb{R}$ defined by

$$f^*(y) = \sup_{x \in U} (y^\top x - f(x)), \quad y \in \mathbb{R}^n.$$

If the conditions of Theorem 50.19(1) hold, which in our case means that for every $\lambda \in \mathbb{R}^m$, there is a unique $u_\lambda \in \mathbb{R}^n$ such that

$$G(\lambda) = L(u_\lambda, \lambda) = \inf_{u \in \mathbb{R}^n} L(u, \lambda),$$

and that the function $\lambda \mapsto u_\lambda$ is continuous, then G is differentiable. Furthermore, we have

$$\nabla G_\lambda = Au_\lambda - b,$$

and for any solution $\mu = \lambda^*$ of the dual problem

$$\begin{aligned} &\text{maximize} && G(\lambda) \\ &\text{subject to} && \lambda \in \mathbb{R}^m, \end{aligned}$$

the vector $u^* = u_\mu$ is a solution of the primal Problem (P). Furthermore, $J(u^*) = G(\lambda^*)$, that is, the duality gap is zero.

The dual ascent method is essentially gradient descent applied to the dual function G . But since G is maximized, gradient descent becomes gradient ascent. Also, we no longer worry that the minimization problem $\inf_{u \in \mathbb{R}^n} L(u, \lambda)$ has a unique solution, so we denote by u^+ some minimizer of the above problem, namely

$$u^+ = \arg \min_u L(u, \lambda).$$

Given some initial dual variable λ^0 , the *dual ascent method* consists of the following two steps:

$$\begin{aligned} u^{k+1} &= \arg \min_u L(u, \lambda^k) \\ \lambda^{k+1} &= \lambda^k + \alpha^k (Au^{k+1} - b), \end{aligned}$$

where $\alpha^k > 0$ is a step size. The first step is used to compute the “new gradient” (indeed, if the minimizer u^{k+1} is unique, then $\nabla G_{\lambda^k} = Au^{k+1} - b$), and the second step is a dual variable update.

Example 52.1. Let us look at a very simple example of the gradient ascent method applied to a problem we first encountered in Section 42.1, namely minimize $J(x, y) = (1/2)(x^2 + y^2)$ subject to $2x - y = 5$. The Lagrangian is

$$L(x, y, \lambda) = \frac{1}{2}(x^2 + y^2) + \lambda(2x - y - 5).$$

See Figure 52.1.

The method of Lagrangian duality says first calculate

$$G(\lambda) = \inf_{(x,y) \in \mathbb{R}^2} L(x, y, \lambda).$$

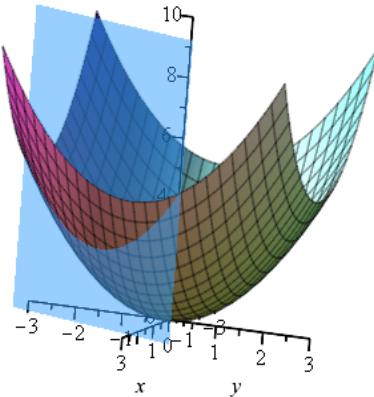

Figure 52.1: The graph of $J(x, y) = (1/2)(x^2 + y^2)$ is the parabolic surface while the graph of $2x - y = 5$ is the transparent blue plane. The solution to Example 52.1 is apex of the intersection curve, namely the point $(2, -1, \frac{5}{2})$.

Since

$$J(x, y) = \frac{1}{2} \begin{pmatrix} x & y \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix},$$

we observe that $J(x, y)$ is a quadratic function determined by the positive definite matrix $\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$, and hence to calculate $G(\lambda)$, we must set $\nabla L_{x,y} = 0$. By calculating $\frac{\partial J}{\partial x} = 0$ and $\frac{\partial J}{\partial y} = 0$, we find that $x = -2\lambda$ and $y = \lambda$. Then $G(\lambda) = -5/2\lambda^2 - 5\lambda$, and we must calculate the maximum of $G(\lambda)$ with respect to $\lambda \in \mathbb{R}$. This means calculating $G'(\lambda) = 0$ and obtaining $\lambda = -1$ for the solution of $(x, y, \lambda) = (-2\lambda, \lambda, \lambda) = (2, -1, -1)$.

Instead of solving *directly* for λ in terms of (x, y) , the method of dual ascent begins with a *numerical* estimate for λ , namely λ^0 , and forms the “numerical” Lagrangian

$$L(x, y, \lambda^0) = \frac{1}{2}(x^2 + y^2) + \lambda^0(2x - y - 5).$$

With this numerical value λ^0 , we minimize $L(x, y, \lambda^0)$ with respect to (x, y) . This calculation will be identical to that used to form $G(\lambda)$ above, and as such, we obtain the iterative step $(x^1, y^1) = (-2\lambda^0, \lambda^0)$. So if we replace λ^0 by λ^k , we have the first step of the dual ascent method, namely

$$u^{k+1} = \begin{pmatrix} x^{k+1} \\ y^{k+1} \end{pmatrix} = \begin{pmatrix} -2 \\ 1 \end{pmatrix} \lambda^k.$$

The second step of the dual ascent method refines the numerical estimate of λ by calculating

$$\lambda^{k+1} = \lambda^k + \alpha^k \left((2 \quad -1) \begin{pmatrix} x^{k+1} \\ y^{k+1} \end{pmatrix} - 5 \right).$$

(Recall that in our original problem the constraint is $2x - y = 5$ or $\begin{pmatrix} 2 & -1 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = 5$, so $A = \begin{pmatrix} 2 & -1 \end{pmatrix}$ and $b = 5$.) By simplifying the above equation, we find that

$$\lambda^{k+1} = (1 - \beta)\lambda^k - \beta, \quad \beta = 5\alpha^k.$$

Back substituting for λ^k in the preceding equation shows that

$$\lambda^{k+1} = (1 - \beta)^{k+1}\lambda^0 + (1 - \beta)^{k+1} - 1.$$

If $0 < \beta \leq 1$, the preceding line implies that λ^{k+1} converges to $\lambda = -1$, which coincides with the answer provided by the original Lagrangian duality method. Observe that if $\beta = 1$ or $\alpha^k = \frac{1}{5}$, the dual ascent method terminates in one step.

With an appropriate choice of α^k , we have $G(\lambda^{k+1}) > G(\lambda^k)$, so the method makes progress. Under certain assumptions, for example, that J is strictly convex and some conditions of the α^k , it can be shown that dual ascent converges to an optimal solution (both for the primal and the dual). However, the main flaw of dual ascent is that the minimization step may diverge. For example, this happens if J is a nonzero affine function of one of its components. The remedy is to add a penalty term to the Lagrangian.

On the positive side, the dual ascent method leads to a decentralized algorithm if the function J is separable. Suppose that u can be split as $u = \sum_{i=1}^N u_i$, with $u_i \in \mathbb{R}^{n_i}$ and $n = \sum_{i=1}^N n_i$, that

$$J(u) = \sum_{i=1}^N J_i(u_i),$$

and that A is split into N blocks A_i (with A_i a $m \times n_i$ matrix) as $A = [A_1 \cdots A_N]$, so that $Au = \sum_{i=1}^N A_i u_i$. Then the Lagrangian can be written as

$$L(u, \lambda) = \sum_{i=1}^N L_i(u_i, \lambda),$$

with

$$L_i(u_i, \lambda) = J_i(u_i) + \lambda^\top \left(A_i u_i - \frac{1}{N} b \right).$$

it follows that the minimization of $L(u, \lambda)$ with respect to the primal variable u can be split into N separate minimization problems that can be solved in parallel. The algorithm then performs the N updates

$$u_i^{k+1} = \arg \min_{u_i} L_i(u_i, \lambda^k)$$

in parallel, and then the step

$$\lambda^{k+1} = \lambda^k + \alpha^k (Au^{k+1} - b).$$

52.2 Augmented Lagrangians and the Method of Multipliers

In order to make the minimization step of the dual ascent method more robust, one can use the trick of adding the penalty term $(\rho/2) \|Au - b\|_2^2$ to the Lagrangian.

Definition 52.1. Given the Optimization Problem (P),

$$\begin{aligned} & \text{minimize } J(u) \\ & \text{subject to } Au = b, \end{aligned}$$

the *augmented Lagrangian* is given by

$$L_\rho(u, \lambda) = J(u) + \lambda^\top(Au - b) + (\rho/2) \|Au - b\|_2^2,$$

with $\lambda \in \mathbb{R}^m$, and where $\rho > 0$ is called the *penalty parameter*.

The augmented Lagrangian $L_\rho(u, \lambda)$ can be viewed as the ordinary Lagrangian of the Minimization Problem (P_ρ) ,

$$\begin{aligned} & \text{minimize } J(u) + (\rho/2) \|Au - b\|_2^2 \\ & \text{subject to } Au = b. \end{aligned}$$

The above problem is equivalent to Program (P), since for any feasible solution of (P_ρ) , we must have $Au - b = 0$.

The benefit of adding the penalty term $(\rho/2) \|Au - b\|_2^2$ is that by Proposition 51.37, Problem (P_ρ) has a unique optimal solution under mild conditions on A .

Dual ascent applied to the dual of (P_ρ) yields the *method of multipliers*, which consists of the following steps, given some initial λ^0 :

$$\begin{aligned} u^{k+1} &= \arg \min_u L_\rho(u, \lambda^k) \\ \lambda^{k+1} &= \lambda^k + \rho(Au^{k+1} - b). \end{aligned}$$

Observe that the second step uses the parameter ρ . The reason is that it can be shown that choosing $\alpha^k = \rho$ guarantees that (u^{k+1}, λ^{k+1}) satisfies the equation

$$\nabla J_{u^{k+1}} + A^\top \lambda^{k+1} = 0,$$

which means that (u^{k+1}, λ^{k+1}) is dual feasible; see Boyd, Parikh, Chu, Peleato and Eckstein [28], Section 2.3.

Example 52.2. Consider the minimization problem

$$\begin{aligned} & \text{minimize } y^2 + 2x \\ & \text{subject to } 2x - y = 0. \end{aligned}$$

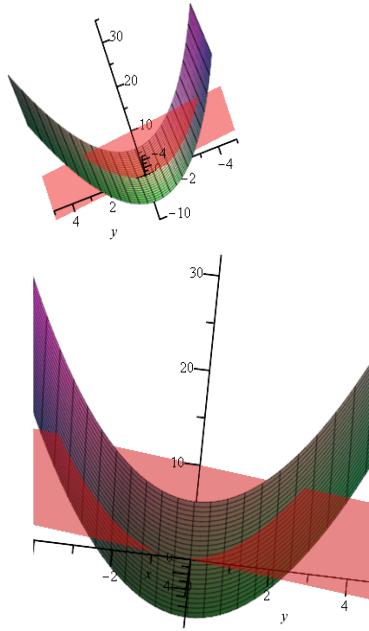

Figure 52.2: Two views of the graph of $y^2 + 2x$ intersected with the transparent red plane $2x - y = 0$. The solution to Example 52.2 is apex of the intersection curve, namely the point $(-\frac{1}{4}, -\frac{1}{2}, -\frac{15}{16})$.

See Figure 52.2.

The quadratic function

$$J(x, y) = y^2 + 2x = \begin{pmatrix} x & y \end{pmatrix} \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} + \begin{pmatrix} 2 & 0 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix}$$

is convex but not strictly convex. Since $y = 2x$, the problem is equivalent to minimizing $y^2 + 2x = 4x^2 + 2x$, whose minimum is achieved for $x = -1/4$ (since setting the derivative of the function $x \mapsto 4x^2 + 2$ yields $8x + 2 = 0$). Thus, the unique minimum of our problem is achieved for $(x = -1/4, y = -1/2)$. The Lagrangian of our problem is

$$L(x, y, \lambda) = y^2 + 2x + \lambda(2x - y).$$

If we apply the dual ascent method, minimization of $L(x, y, \lambda)$ with respect to x and y holding λ constant yields the equations

$$\begin{aligned} 2 + 2\lambda &= 0 \\ 2y - \lambda &= 0, \end{aligned}$$

obtained by setting the gradient of L (with respect to x and y) to zero. If $\lambda \neq -1$, the problem has no solution. Indeed, if $\lambda \neq -1$, minimizing $L(x, y, \lambda) = y^2 + 2x + \lambda(2x - y)$ with respect to x and y yields $-\infty$.

The augmented Lagrangian is

$$\begin{aligned} L_\rho(x, y, \lambda) &= y^2 + 2x + \lambda(2x - y) + (\rho/2)(2x - y)^2 \\ &= 2\rho x^2 - 2\rho xy + 2(1 + \lambda)x - \lambda y + \left(1 + \frac{\rho}{2}\right)y^2, \end{aligned}$$

which in matrix form is

$$L_\rho(x, y, \lambda) = \begin{pmatrix} x & y \end{pmatrix} \begin{pmatrix} 2\rho^2 & -\rho \\ -\rho & 1 + \frac{\rho}{2} \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} + \begin{pmatrix} 2(1 + \lambda) & -\lambda \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix}.$$

The trace of the above matrix is $1 + \frac{\rho}{2} + 2\rho^2 > 0$, and the determinant is

$$2\rho^2 \left(1 + \frac{\rho}{2}\right) - \rho^2 = \rho^2(1 + \rho) > 0,$$

since $\rho > 0$. Therefore, the above matrix is symmetric positive definite. Minimizing $L_\rho(x, y, \lambda)$ with respect to x and y , we set the gradient of $L_\rho(x, y, \lambda)$ (with respect to x and y) to zero, and we obtain the equations:

$$\begin{aligned} 2\rho x - \rho y + (1 + \lambda) &= 0 \\ -2\rho x + (2 + \rho)y - \lambda &= 0. \end{aligned}$$

The solution is

$$x = -\frac{1}{4} - \frac{1 + \lambda}{2\rho}, \quad y = -\frac{1}{2}.$$

Thus the steps for the method of multipliers are

$$\begin{aligned} x^{k+1} &= -\frac{1}{4} - \frac{1 + \lambda^k}{2\rho} \\ y^{k+1} &= -\frac{1}{2} \\ \lambda^{k+1} &= \lambda^k + \rho \begin{pmatrix} 2 & -1 \end{pmatrix} \begin{pmatrix} -\frac{1}{4} - \frac{1 + \lambda^k}{2\rho} \\ -\frac{1}{2} \end{pmatrix}, \end{aligned}$$

and the second step simplifies to

$$\lambda^{k+1} = -1.$$

Consequently, we see that the method converges after two steps for any initial value of λ^0 , and we get

$$x = -\frac{1}{4}, \quad y = -\frac{1}{2}, \quad \lambda = -1.$$

The method of multipliers also converges for functions J that are not even convex, as illustrated by the next example.

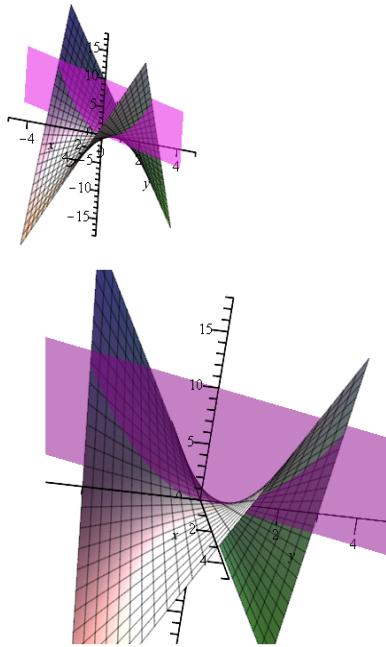

Figure 52.3: Two views of the graph of the saddle of $2xy$ ($\beta = 1$) intersected with the transparent magenta plane $2x - y = 0$. The solution to Example 52.3 is apex of the intersection curve, namely the point $(0, 0, 0)$.

Example 52.3. Consider the minimization problem

$$\begin{aligned} &\text{minimize} && 2\beta xy \\ &\text{subject to} && 2x - y = 0, \end{aligned}$$

with $\beta > 0$. See Figure 52.3.

The quadratic function

$$J(x, y) = 2\beta xy = \begin{pmatrix} x & y \end{pmatrix} \begin{pmatrix} 0 & \beta \\ \beta & 0 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix}$$

is not convex because the above matrix is not even positive semidefinite (the eigenvalues of the matrix are $-\beta$ and $+\beta$). The augmented Lagrangian is

$$\begin{aligned} L_\rho(x, y, \lambda) &= 2\beta xy + \lambda(2x - y) + (\rho/2)(2x - y)^2 \\ &= 2\rho x^2 + 2(\beta - \rho)xy + 2\lambda x - \lambda y + \frac{\rho}{2}y^2, \end{aligned}$$

which in matrix form is

$$L_\rho(x, y, \lambda) = \begin{pmatrix} x & y \end{pmatrix} \begin{pmatrix} 2\rho & \beta - \rho \\ \beta - \rho & \frac{\rho}{2} \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} + (2\lambda - \lambda) \begin{pmatrix} x \\ y \end{pmatrix}.$$

The trace of the above matrix is $2\rho + \frac{\rho}{2} = \frac{5}{2}\rho > 0$, and the determinant is

$$\rho^2 - (\beta - \rho)^2 = \beta(2\rho - \beta).$$

This determinant is positive if $\rho > \beta/2$, in which case the matrix is symmetric positive definite. Minimizing $L_\rho(x, y, \lambda)$ with respect to x and y , we set the gradient of $L_\rho(x, y, \lambda)$ (with respect to x and y) to zero, and we obtain the equations:

$$\begin{aligned} 2\rho x + (\beta - \rho)y + \lambda &= 0 \\ 2(\beta - \rho)x + \rho y - \lambda &= 0. \end{aligned}$$

Since we are assuming that $\rho > \beta/2$, the solutions are

$$x = -\frac{\lambda}{2(2\rho - \beta)}, \quad y = \frac{\lambda}{(2\rho - \beta)}.$$

Thus the steps for the method of multipliers are

$$\begin{aligned} x^{k+1} &= -\frac{\lambda^k}{2(2\rho - \beta)} \\ y^{k+1} &= \frac{\lambda^k}{(2\rho - \beta)} \\ \lambda^{k+1} &= \lambda^k + \frac{\rho}{2(2\rho - \beta)} \begin{pmatrix} 2 & -1 \end{pmatrix} \begin{pmatrix} -\lambda^k \\ 2\lambda^k \end{pmatrix}, \end{aligned}$$

and the second step simplifies to

$$\lambda^{k+1} = \lambda^k + \frac{\rho}{2(2\rho - \beta)}(-4\lambda^k),$$

that is,

$$\lambda^{k+1} = -\frac{\beta}{2\rho - \beta}\lambda^k.$$

If we pick $\rho > \beta > 0$, which implies that $\rho > \beta/2$, then

$$\frac{\beta}{2\rho - \beta} < 1,$$

and the method converges for any initial value λ^0 to the solution

$$x = 0, \quad y = 0, \quad \lambda = 0.$$

Indeed, since the constraint $2x - y = 0$ holds, $2\beta xy = 4\beta x^2$, and the minimum of the function $x \mapsto 4\beta x^2$ is achieved for $x = 0$ (since $\beta > 0$).

As an exercise, the reader should verify that dual ascent (with $\alpha^k = \rho$) yields the equations

$$\begin{aligned}x^{k+1} &= \frac{\lambda^k}{2\beta} \\y^{k+1} &= -\frac{\lambda^k}{\beta} \\\lambda^{k+1} &= \left(1 + \frac{2\rho}{\beta}\right) \lambda^k,\end{aligned}$$

and so the method diverges, except for $\lambda^0 = 0$, which is the optimal solution.

The method of multipliers converges under conditions that are far more general than the dual ascent. However, the addition of the penalty term has the negative effect that even if J is separable, then the Lagrangian L_ρ is not separable. Thus the basic method of multipliers cannot be used for decomposition and is not parallelizable. The next method deals with the problem of separability.

52.3 ADMM: Alternating Direction Method of Multipliers

The alternating direction method of multipliers, for short ADMM, combines the decomposability of dual ascent with the superior convergence properties of the method of multipliers. It can be viewed as an approximation of the method of multipliers, but it is generally superior.

The idea is to split the function J into two independent parts, as $J(x, z) = f(x) + g(z)$, and to consider the [Minimization Problem \(\$P_{\text{admm}}\$ \)](#),

$$\begin{aligned}&\text{minimize} && f(x) + g(z) \\&\text{subject to} && Ax + Bz = c,\end{aligned}$$

for some $p \times n$ matrix A , some $p \times m$ matrix B , and with $x \in \mathbb{R}^n$, $z \in \mathbb{R}^m$, and $c \in \mathbb{R}^p$. We also assume that f and g are convex. Further conditions will be added later.

As in the method of multipliers, we form the *augmented Lagrangian*

$$L_\rho(x, z, \lambda) = f(x) + g(z) + \lambda^\top(Ax + Bz - c) + (\rho/2) \|Ax + Bz - c\|_2^2,$$

with $\lambda \in \mathbb{R}^p$ and for some $\rho > 0$.

Given some initial values (z^0, λ^0) , the *ADMM method* consists of the following iterative steps:

$$\begin{aligned}x^{k+1} &= \arg \min_x L_\rho(x, z^k, \lambda^k) \\z^{k+1} &= \arg \min_z L_\rho(x^{k+1}, z, \lambda^k) \\\lambda^{k+1} &= \lambda^k + \rho(Ax^{k+1} + Bz^{k+1} - c).\end{aligned}$$

Instead of performing a minimization step jointly over x and z , as the method of multipliers would in the step

$$(x^{k+1}, z^{k+1}) = \arg \min_{x,z} L_\rho(x, z, \lambda^k),$$

ADMM first performs an x -minimization step, and then a z -minimization step. Thus x and z are updated in an alternating or sequential fashion, which accounts for the term *alternating direction*.

The algorithm state in ADMM is (z^k, λ^k) , in the sense that (z^{k+1}, λ^{k+1}) is a function of (z^k, λ^k) . The variable x^{k+1} is an auxiliary variable which is used to compute z^{k+1} from (z^k, λ^k) . The roles of x and z are not quite symmetric, since the update of x is done before the update of λ . By switching x and z , f and g and A and B , we obtain a variant of ADMM in which the order of the x -update step and the z -update step are reversed.

Example 52.4. Let us reconsider the problem of Example 52.2 to solve it using ADMM. We formulate the problem as

$$\begin{aligned} & \text{minimize} && 2x + z^2 \\ & \text{subject to} && 2x - z = 0, \end{aligned}$$

with $f(x) = 2x$ and $g(z) = z^2$. The augmented Lagrangian is given by

$$L_\rho(x, z, \lambda) = 2x + z^2 + 2\lambda x - \lambda z + 2\rho x^2 - 2\rho xz + \frac{\rho}{2}z^2.$$

The ADMM steps are as follows. The x -update is

$$x^{k+1} = \arg \min_x (2\rho x^2 - 2\rho x z^k + 2\lambda^k x + 2x),$$

and since this is a quadratic function in x , its minimum is achieved when the derivative of the above function (with respect to x) is zero, namely

$$x^{k+1} = \frac{1}{2}z^k - \frac{1}{2\rho}\lambda^k - \frac{1}{2\rho}. \quad (1)$$

The z -update is

$$z^{k+1} = \arg \min_z \left(z^2 + \frac{\rho}{2}z^2 - 2\rho x^{k+1} z - \lambda^k z \right),$$

and as for the x -step, the minimum is achieved when the derivative of the above function (with respect to z) is zero, namely

$$z^{k+1} = \frac{2\rho x^{k+1}}{\rho + 2} + \frac{\lambda^k}{\rho + 2}. \quad (2)$$

The λ -update is

$$\lambda^{k+1} = \lambda^k + \rho(2x^{k+1} - z^{k+1}). \quad (3)$$

Substituting the right hand side of (1) for x^{k+1} in (2) yields

$$z^{k+1} = \frac{\rho z^k}{\rho + 2} - \frac{1}{\rho + 2}. \quad (4)$$

Using (2), we obtain

$$2x^{k+1} - z^{k+1} = \frac{4x^{k+1}}{\rho + 2} - \frac{\lambda^k}{\rho + 2}, \quad (5)$$

and then using (3) we get

$$\lambda^{k+1} = \frac{2\lambda^k}{\rho + 2} + \frac{4\rho x^{k+1}}{\rho + 2}. \quad (6)$$

Substituting the right hand side of (1) for x^{k+1} in (6), we obtain

$$\lambda^{k+1} = \frac{2\rho z^k}{\rho + 2} - \frac{2}{\rho + 2}. \quad (7)$$

Equation (7) shows that z^k determines λ^{k+1} , and Equation (1) for $k+2$, along with Equation (4), shows that z^k also determines x^{k+2} . In particular, we find that

$$\begin{aligned} x^{k+2} &= \frac{1}{2}z^{k+1} - \frac{1}{2\rho}\lambda^{k+1} - \frac{1}{2\rho} \\ &= \frac{(\rho - 2)z^k}{2(\rho + 2)} - \frac{1}{\rho + 2}. \end{aligned}$$

Thus it suffices to find the limit of the sequence (z^k) . Since we already know from Example 52.2 that this limit is $-1/2$, using (4), we write

$$z^{k+1} = -\frac{1}{2} + \frac{\rho z^k}{\rho + 2} - \frac{1}{\rho + 2} + \frac{1}{2} = -\frac{1}{2} + \frac{\rho}{\rho + 2} \left(\frac{1}{2} + z^k \right).$$

By induction, we deduce that

$$z^{k+1} = -\frac{1}{2} + \left(\frac{\rho}{\rho + 2} \right)^{k+1} \left(\frac{1}{2} + z^0 \right),$$

and since $\rho > 0$, we have $\rho/(\rho + 2) < 1$, so the limit of the sequence (z^{k+1}) is indeed $-1/2$, and consequently the limit of (λ^{k+1}) is -1 and the limit of x^{k+2} is $-1/4$.

For ADMM to be practical, the x -minimization step and the z -minimization step have to be doable efficiently.

It is often convenient to write the ADMM updates in terms of the *scaled dual variable* $\mu = (1/\rho)\lambda$. If we define the *residual* as

$$r = Ax + bz - c,$$

then we have

$$\begin{aligned}\lambda^\top r + (\rho/2) \|r\|_2^2 &= (\rho/2) \|r + (1/\rho)\lambda\|_2^2 - (1/(2\rho)) \|\lambda\|_2^2 \\ &= (\rho/2) \|r + \mu\|_2^2 - (\rho/2) \|\mu\|_2^2.\end{aligned}$$

The *scaled form of ADMM* consists of the following steps:

$$\begin{aligned}x^{k+1} &= \arg \min_x \left(f(x) + (\rho/2) \|Ax + Bz^k - c + \mu^k\|_2^2 \right) \\ z^{k+1} &= \arg \min_z \left(g(z) + (\rho/2) \|Ax^{k+1} + Bz - c + \mu^k\|_2^2 \right) \\ \mu^{k+1} &= \mu^k + Ax^{k+1} + Bz^{k+1} - c.\end{aligned}$$

If we define the *residual* r^k at step k as

$$r^k = Ax^k + Bz^k - c = \mu^k - \mu^{k-1} = (1/\rho)(\lambda^k - \lambda^{k-1}),$$

then we see that

$$r = u^0 + \sum_{j=1}^k r^j.$$

The formulae in the scaled form are often shorter than the formulae in the unscaled form.

We now discuss the convergence of ADMM.

52.4 Convergence of ADMM \circledast

Let us repeat the steps of ADMM: Given some initial (z^0, λ^0) , do:

$$\begin{aligned}x^{k+1} &= \arg \min_x L_\rho(x, z^k, \lambda^k) && \text{(x-update)} \\ z^{k+1} &= \arg \min_z L_\rho(x^{k+1}, z, \lambda^k) && \text{(z-update)} \\ \lambda^{k+1} &= \lambda^k + \rho(Ax^{k+1} + Bz^{k+1} - c). && \text{(\lambda-update)}\end{aligned}$$

The convergence of ADMM can be proven under the following three assumptions:

- (1) The functions $f: \mathbb{R} \rightarrow \mathbb{R} \cup \{+\infty\}$ and $g: \mathbb{R} \rightarrow \mathbb{R} \cup \{+\infty\}$ are proper and closed convex functions (see Section 51.1) such that $\text{relint}(\text{dom}(f)) \cap \text{relint}(\text{dom}(g)) \neq \emptyset$.
- (2) The $n \times n$ matrix $A^\top A$ is invertible and the $m \times m$ matrix $B^\top B$ is invertible. Equivalently, the $p \times n$ matrix A has rank n and the $p \times m$ matrix has rank m .
- (3) The unaugmented Lagrangian $L_0(x, z, \lambda) = f(x) + g(z) + \lambda^\top (Ax + Bz - c)$ has a saddle point, which means there exists x^*, z^*, λ^* (not necessarily unique) such that

$$L_0(x^*, z^*, \lambda) \leq L_0(x^*, z^*, \lambda^*) \leq L_0(x, z, \lambda^*)$$

for all x, z, λ .

Recall that the augmented Lagrangian is given by

$$L_\rho(x, z, \lambda) = f(x) + g(z) + \lambda^\top(Ax + Bz - c) + (\rho/2) \|Ax + Bz - c\|_2^2.$$

For z (and λ) fixed, we have

$$\begin{aligned} L_\rho(x, z, \lambda) &= f(x) + g(z) + \lambda^\top(Ax + Bz - c) + (\rho/2)(Ax + Bz - c)^\top(Ax + Bz - c) \\ &= f(x) + (\rho/2)x^\top A^\top Ax + (\lambda^\top + \rho(Bz - c)^\top)Ax \\ &\quad + g(z) + \lambda^\top(Bz - c) + (\rho/2)(Bz - c)^\top(Bz - c). \end{aligned}$$

Assume that (1) and (2) hold. Since $A^\top A$ is invertible, then it is symmetric positive definite, and by Proposition 51.37 the x -minimization step has a unique solution (the minimization problem succeeds with a unique minimizer).

Similarly, for x (and λ) fixed, we have

$$\begin{aligned} L_\rho(x, z, \lambda) &= f(x) + g(z) + \lambda^\top(Ax + Bz - c) + (\rho/2)(Ax + Bz - c)^\top(Ax + Bz - c) \\ &= g(z) + (\rho/2)z^\top B^\top Bz + (\lambda^\top + \rho(Ax - c)^\top)Bz \\ &\quad + f(x) + \lambda^\top(Ax - c) + (\rho/2)(Ax - c)^\top(Ax - c). \end{aligned}$$

Since $B^\top B$ is invertible, then it is symmetric positive definite, and by Proposition 51.37 the z -minimization step has a unique solution (the minimization problem succeeds with a unique minimizer).

By Theorem 51.41, Assumption (3) is equivalent to the fact that the KKT equations are satisfied by some triple (x^*, z^*, λ^*) , namely

$$Ax^* + Bz^* - c = 0 \tag{*}$$

and

$$0 \in \partial f(x^*) + \partial g(z^*) + A^\top \lambda^* + B^\top \lambda^*, \tag{\dagger}$$

Assumption (3) is also equivalent to Conditions (a) and (b) of Theorem 51.41. In particular, our program has an optimal solution (x^*, z^*) . By Theorem 51.43, λ^* is maximizer of the dual function $G(\lambda) = \inf_{x,z} L_0(x, z, \lambda)$ and strong duality holds, that is, $G(\lambda^*) = f(x^*) + g(z^*)$ (the duality gap is zero).

We will see after the proof of Theorem 52.1 that Assumption (2) is actually implied by Assumption (3). This allows us to prove a convergence result stronger than the convergence result proven in Boyd et al. [28] under the exact same assumptions (1) and (3).

Let p^* be the minimum value of $f+g$ over the convex set $\{(x, z) \in \mathbb{R}^{m+p} \mid Ax+Bz-c=0\}$, and let (p^k) be the sequence given by $p^k = f(x^k) + g(z^k)$, and recall that $r^k = Ax^k + Bz^k - c$.

Our main goal is to prove the following result.

Theorem 52.1. *Suppose the following assumptions hold:*

- (1) The functions $f: \mathbb{R} \rightarrow \mathbb{R} \cup \{+\infty\}$ and $g: \mathbb{R} \rightarrow \mathbb{R} \cup \{+\infty\}$ are proper and closed convex functions (see Section 51.1) such that $\text{relint}(\text{dom}(f)) \cap \text{relint}(\text{dom}(g)) \neq \emptyset$.
- (2) The $n \times n$ matrix $A^\top A$ is invertible and the $m \times m$ matrix $B^\top B$ is invertible. Equivalently, the $p \times n$ matrix A has rank n and the $p \times m$ matrix has rank m . (This assumption is actually redundant, because it is implied by Assumption (3)).
- (3) The unaugmented Lagrangian $L_0(x, z, \lambda) = f(x) + g(z) + \lambda^\top(Ax + Bz - c)$ has a saddle point, which means there exists x^*, z^*, λ^* (not necessarily unique) such that

$$L_0(x^*, z^*, \lambda) \leq L_0(x^*, z^*, \lambda^*) \leq L_0(x, z, \lambda^*)$$

for all x, z, λ .

Then for any initial values (z^0, λ^0) , the following properties hold:

- (1) The sequence (r^k) converges to 0 (residual convergence).
- (2) The sequence (p^k) converge to p^* (objective convergence).
- (3) The sequences (x^k) and (z^k) converge to an optimal solution (\tilde{x}, \tilde{z}) of Problem (P_{admm}) and the sequence (λ^k) converges an optimal solution $\tilde{\lambda}$ of the dual problem (primal and dual variable convergence).

Proof. The core of the proof is due to Boyd et al. [28], but there are new steps because we have the stronger hypothesis (2), which yield the stronger result (3).

The proof consists of several steps. It is not possible to prove directly that the sequences (x^k) , (z^k) , and (λ^k) converge, so first we prove that the sequence (r^{k+1}) converges to zero, and that the sequences (Ax^{k+1}) and (Bz^{k+1}) also converge.

Step 1. Prove the inequality (A1) below.

Consider the sequence of reals (V^k) given by

$$V^k = (1/\rho) \|\lambda^k - \lambda^*\|_2^2 + \rho \|B(z^k - z^*)\|_2^2.$$

It can be shown that the V^k satisfy the following inequality:

$$V^{k+1} \leq V^k - \rho \|r^{k+1}\|_2^2 - \rho \|B(z^{k+1} - z^k)\|_2^2. \quad (\text{A1})$$

This is rather arduous. Since a complete proof is given in Boyd et al. [28], we will only provide some of the key steps later.

Inequality (A1) shows that the sequence (V^k) in nonincreasing. If we write these inequalities for $k, k-1, \dots, 0$, we have

$$\begin{aligned} V^{k+1} &\leq V^k - \rho \|r^{k+1}\|_2^2 - \rho \|B(z^{k+1} - z^k)\|_2^2 \\ V^k &\leq V^{k-1} - \rho \|r^k\|_2^2 - \rho \|B(z^k - z^{k-1})\|_2^2 \\ &\vdots \\ V^1 &\leq V^0 - \rho \|r^1\|_2^2 - \rho \|B(z^1 - z^0)\|_2^2, \end{aligned}$$

and by adding up these inequalities, we obtain

$$V^{k+1} \leq V^0 - \rho \sum_{j=0}^k \left(\|r^{j+1}\|_2^2 + \|B(z^{j+1} - z^j)\|_2^2 \right),$$

which implies that

$$\rho \sum_{j=0}^k \left(\|r^{j+1}\|_2^2 + \|B(z^{j+1} - z^j)\|_2^2 \right) \leq V_0 - V^{k+1} \leq V^0, \quad (\text{B})$$

since $V^{k+1} \leq V^0$.

Step 2. Prove that the sequence (r^k) converges to 0, and that the sequences (Ax^{k+1}) and (Bz^{k+1}) also converge.

Inequality (B) implies that the series $\sum_{k=1}^{\infty} r^k$ and $\sum_{k=0}^{\infty} B(z^{k+1} - z^k)$ converge absolutely. In particular, the sequence (r^k) converges to 0.

The n th partial sum of the series $\sum_{k=0}^{\infty} B(z^{k+1} - z^k)$ is

$$\sum_{k=0}^n B(z^{k+1} - z^k) = B(z^{n+1} - z^0),$$

and since the series $\sum_{k=0}^{\infty} B(z^{k+1} - z^k)$ converges, we deduce that the sequence (Bz^{k+1}) converges. Since $Ax^{k+1} + Bz^{k+1} - c = r^{k+1}$, the convergence of (r^{k+1}) and (Bz^{k+1}) implies that the sequence (Ax^{k+1}) also converges.

Step 3. Prove that the sequences (x^{k+1}) and (z^{k+1}) converge. By Assumption (2), the matrices $A^\top A$ and $B^\top B$ are invertible, so multiplying each vector Ax^{k+1} by $(A^\top A)^{-1}A^\top$, if the sequence (Ax^{k+1}) converges to u , then the sequence (x^{k+1}) converges to $(A^\top A)^{-1}A^\top u$. Similarly, if the sequence (Bz^{k+1}) converges to v , then the sequence (z^{k+1}) converges to $(B^\top B)^{-1}B^\top v$.

Step 4. Prove that the sequence (λ^k) converges.

Recall that

$$\lambda^{k+1} = \lambda^k + \rho r^{k+1}.$$

It follows by induction that

$$\lambda^{k+p} = \lambda^k + \rho(r^{k+1} + \dots + r^{k+p}), \quad p \geq 2.$$

As a consequence, we get

$$\|\lambda^{k+p} - \lambda^k\| \leq \rho(\|r^{k+1}\| + \dots + \|r^{k+p}\|).$$

Since the series $\sum_{k=1}^{\infty} \|r^k\|$ converges, the partial sums form a Cauchy sequence, and this immediately implies that for any $\epsilon > 0$ we can find $N > 0$ such that

$$\rho(\|r^{k+1}\| + \dots + \|r^{k+p}\|) < \epsilon, \quad \text{for all } k, p+k \geq N,$$

so the sequence (λ^k) is also a Cauchy sequence, thus it converges.

Step 5. Prove that the sequence (p^k) converges to p^* .

For this, we need two more inequalities. Following Boyd et al. [28], we need to prove that

$$p^{k+1} - p^* \leq -(\lambda^{k+1})^\top r^{k+1} - \rho(B(z^{k+1} - z^k))^\top (-r^{k+1} + B(z^{k+1} - z^*)) \quad (\text{A2})$$

and

$$p^* - p^{k+1} \leq (\lambda^*)^\top r^{k+1}. \quad (\text{A3})$$

Since we proved that the sequence (r^k) and $B(z^{k+1} - z^k)$ converge to 0, and that the sequence (λ^{k+1}) converges, from

$$(\lambda^{k+1})^\top r^{k+1} + \rho(B(z^{k+1} - z^k))^\top (-r^{k+1} + B(z^{k+1} - z^*)) \leq p^* - p^{k+1} \leq (\lambda^*)^\top r^{k+1},$$

we deduce that in the limit, p^{k+1} converges to p^* .

Step 6. Prove (A3).

Since (x^*, y^*, λ^*) is a saddle point, we have

$$L_0(x^*, z^*, \lambda^*) \leq L_0(x^{k+1}, z^{k+1}, \lambda^*).$$

Since $Ax^* + Bz^* = c$, we have $L_0(x^*, z^*, \lambda^*) = p^*$, and since $p^{k+1} = f(x^{k+1}) + g(z^{k+1})$, we have

$$L_0(x^{k+1}, z^{k+1}, \lambda^*) = p^{k+1} + (\lambda^*)^\top r^{k+1},$$

so we obtain

$$p^* \leq p^{k+1} + (\lambda^*)^\top r^{k+1},$$

which yields (A3).

Step 7. Prove (A2).

By Proposition 51.34, z^{k+1} minimizes $L_\rho(x^{k+1}, z, \lambda^k)$ iff

$$\begin{aligned} 0 &\in \partial g(z^{k+1}) + B^\top \lambda^k + \rho B^\top (Ax^{k+1} + Bz^{k+1} - c) \\ &= \partial g(z^{k+1}) + B^\top \lambda^k + \rho B^\top r^{k+1} \\ &= \partial g(z^{k+1}) + B^\top \lambda^{k+1}, \end{aligned}$$

since $r^{k+1} = Ax^{k+1} + Bz^{k+1} - c$ and $\lambda^{k+1} = \lambda^k + \rho(Ax^{k+1} + Bz^{k+1} - c)$.

In summary, we have

$$0 \in \partial g(z^{k+1}) + B^\top \lambda^{k+1}, \quad (\dagger_1)$$

which shows that z^{k+1} minimizes the function

$$z \mapsto g(z) + (\lambda^{k+1})^\top Bz.$$

Consequently, we have

$$g(z^{k+1}) + (\lambda^{k+1})^\top Bz^{k+1} \leq g(z^*) + (\lambda^{k+1})^\top Bz^*. \quad (\text{B1})$$

Similarly, x^{k+1} minimizes $L_\rho(x, z^k, \lambda^k)$ iff

$$\begin{aligned} 0 &\in \partial f(x^{k+1}) + A^\top \lambda^k + \rho A^\top (Ax^{k+1} + Bz^k - c) \\ &= \partial f(x^{k+1}) + A^\top (\lambda^k + \rho r^{k+1} + \rho B(z^k - z^{k+1})) \\ &= \partial f(x^{k+1}) + A^\top \lambda^{k+1} + \rho A^\top B(z^k - z^{k+1}) \end{aligned}$$

since $r^{k+1} - Bz^{k+1} = Ax^{k+1} - c$ and $\lambda^{k+1} = \lambda^k + \rho(Ax^{k+1} + Bz^{k+1} - c) = \lambda^k + \rho r^{k+1}$.

Equivalently, the above derivation shows that

$$0 \in \partial f(x^{k+1}) + A^\top (\lambda^{k+1} - \rho B(z^{k+1} - z^k)), \quad (\dagger_2)$$

which shows that x^{k+1} minimizes the function

$$x \mapsto f(x) + (\lambda^{k+1} - \rho B(z^{k+1} - z^k))^\top Ax.$$

Consequently, we have

$$f(x^{k+1}) + (\lambda^{k+1} - \rho B(z^{k+1} - z^k))^\top Ax^{k+1} \leq f(x^*) + (\lambda^{k+1} - \rho B(z^{k+1} - z^k))^\top Ax^*. \quad (\text{B2})$$

Adding up Inequalities (B1) and (B2), using the equation $Ax^* + Bz^* = c$, and rearranging, we obtain inequality (A2).

Step 8. Prove that (x^k) , (z^k) , and (λ^k) converge to optimal solutions.

Recall that (r^k) converges to 0, and that (x^k) , (z^k) , and (λ^k) converge to limits \tilde{x} , \tilde{z} , and $\tilde{\lambda}$. Since $r^k = Ax^k + Bz^k - c$, in the limit, we have

$$A\tilde{x} + B\tilde{z} - c = 0. \quad (*_1)$$

Using (\dagger_1) , in the limit, we obtain

$$0 \in \partial g(\tilde{z}) + B^\top \tilde{\lambda}. \quad (*_2)$$

Since $(B(z^{k+1} - z^k))$ converges to 0, using (\dagger_2) , in the limit, we obtain

$$0 \in \partial f(\tilde{x}) + A^\top \tilde{\lambda}. \quad (*_3)$$

From $(*_2)$ and $(*_3)$, we obtain

$$0 \in \partial f(\tilde{x}) + \partial g(\tilde{z}) + A^\top \tilde{\lambda} + B^\top \tilde{\lambda}. \quad (*_4)$$

But $(*_1)$ and $(*_4)$ are exactly the KKT equations, and by Theorem 51.41, we conclude that $\tilde{x}, \tilde{z}, \tilde{\lambda}$ are optimal solutions.

Step 9. Prove (A1). This is the most tedious step of the proof. We begin by adding up (A2) and (A3), and then perform quite a bit of rewriting and manipulation. The complete derivation can be found in Boyd et al. [28]. \square

Remarks:

- (1) In view of Theorem 51.42, we could replace Assumption (3) by the slightly stronger assumptions that the optimum value of our program is finite and that the constraints are qualified. Since the constraints are affine, this means that there is some feasible solution in $\text{relint}(\text{dom}(f)) \cap \text{relint}(\text{dom}(g))$. These assumptions are more practical than Assumption (3).
- (2) Actually, Assumption (3) implies Assumption (2). Indeed, we know from Theorem 51.41 that the existence of a saddle point implies that our program has a finite optimal solution. However, if either $A^\top A$ or $B^\top B$ is not invertible, then Program (P) may not have a finite optimal solution, as shown by the following counterexample.

Example 52.5. Let

$$f(x, y) = x, \quad g(z) = 0, \quad y - z = 0.$$

Then

$$L_\rho(x, y, z, \lambda) = x + \lambda(y - z) + (\rho/2)(y - z)^2,$$

but minimizing over (x, y) with z held constant yields $-\infty$, which implies that the above program has no finite optimal solution. See Figure 52.4.

The problem is that

$$A = \begin{pmatrix} 0 & 1 \end{pmatrix}, \quad B = \begin{pmatrix} -1 \end{pmatrix},$$

but

$$A^\top A = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}$$

is not invertible.

- (3) Proving (A1), (A2), (A3), and the convergence of (r^k) to 0 and of (p^k) to p^* does not require Assumption (2). The proof, using the ingeneous Inequality (A1) (and (B)) is the proof given in Boyd et al. [28]. We were also able to prove that (λ^k) , (Ax^k) and (Bz^k) converge without Assumption (2), but to prove that (x^k) , (y^k) , and (λ^k) converge to optimal solutions, we had to use Assumption (2).

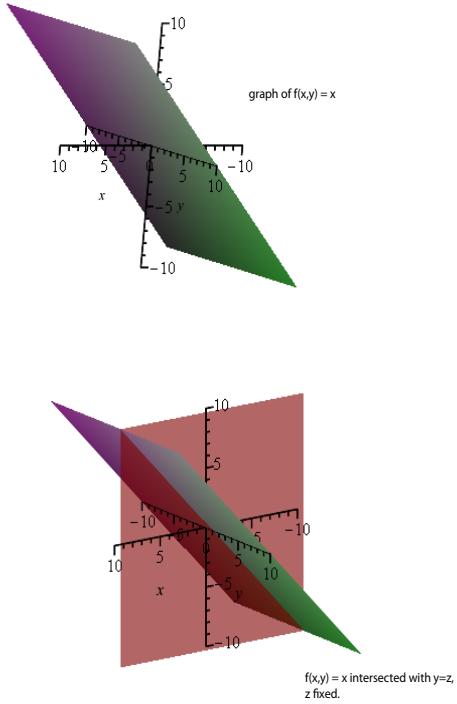

Figure 52.4: A graphical representation of the Example 52.5. This is an illustration of the x minimization step when z is held fixed. Since the intersection of the two planes is an unbounded line, we “see” that minimizing over x yields $-\infty$.

- (4) Bertsekas discusses ADMM in [17], Sections 2.2 and 5.4. His formulation of ADMM is slightly different, namely

$$\begin{aligned} &\text{minimize} && f(x) + g(z) \\ &\text{subject to} && Ax = z. \end{aligned}$$

Bertsekas states a convergence result for this version of ADMM under the hypotheses that either $\text{dom}(f)$ is compact or that $A^\top A$ is invertible, and that a saddle point exists; see Proposition 5.4.1. The proof is given in Bertsekas [20], Section 3.4, Proposition 4.2. It appears that the proof makes use of gradients, so it is not clear that it applies in the more general case where f and g are not differentiable.

- (5) Versions of ADMM are discussed in Gabay [69] (Sections 4 and 5). They are more general than the version discussed here. Some convergence proofs are given, but because Gabay’s framework is more general, it is not clear that they apply to our setting. Also, these proofs rely on earlier result by Lions and Mercier, which makes the comparison difficult.

- (5) Assumption (2) does not imply that the system $Ax + Bz = c$ has any solution. For example, if

$$A = \begin{pmatrix} 1 \\ 1 \end{pmatrix}, \quad B = \begin{pmatrix} -1 \\ -1 \end{pmatrix}, \quad c = \begin{pmatrix} 1 \\ 0 \end{pmatrix},$$

the system

$$\begin{aligned} x - z &= 1 \\ x - z &= 0 \end{aligned}$$

has no solution. However, since Assumption (3) implies that the program has an optimal solution, it implies that c belongs to the column space of the $p \times (n+m)$ matrix $(A \ B)$.

Here is an example where ADMM diverges for a problem whose optimum value is $-\infty$.

Example 52.6. Consider the problem given by

$$f(x) = x, \quad g(z) = 0, \quad x - z = 0.$$

Since $f(x) + g(z) = x$, and $x = z$, the variable x is unconstrained and the above function goes to $-\infty$ when x goes to $-\infty$. The augmented Lagrangian is

$$\begin{aligned} L_\rho(x, z, \lambda) &= x + \lambda(x - z) + \frac{\rho}{2}(x - z)^2 \\ &= \frac{\rho}{2}x^2 - \rho xz + \frac{\rho}{2}z^2 + x + \lambda x - \lambda z. \end{aligned}$$

The matrix

$$\begin{pmatrix} \frac{1}{2} & -\frac{1}{2} \\ -\frac{1}{2} & \frac{1}{2} \end{pmatrix}$$

is singular and $L_\rho(x, z, \lambda)$ goes to $-\infty$ in when $(x, z) = t(1, 1)$ and t goes to $-\infty$. The ADMM steps are:

$$\begin{aligned} x^{k+1} &= z^k - \frac{1}{\rho}\lambda^k - \frac{1}{\rho} \\ z^{k+1} &= x^{k+1} + \frac{1}{\rho}\lambda^k \\ \lambda^{k+1} &= \lambda^k + \rho(x^{k+1} - z^{k+1}), \end{aligned}$$

and these equations hold for all $k \geq 0$. From the last two equations we deduce that

$$\lambda^{k+1} = \lambda^k + \rho(x^{k+1} - z^{k+1}) = \lambda^k + \rho(-\frac{1}{\rho}\lambda^k) = 0, \quad \text{for all } k \geq 0,$$

so

$$z^{k+2} = x^{k+2} + \frac{1}{\rho}\lambda^{k+1} = x^{k+2}, \quad \text{for all } k \geq 0.$$

Consequently we find that

$$x^{k+3} = z^{k+2} + \frac{1}{\rho} \lambda^{k+2} - \frac{1}{\rho} = x^{k+2} - \frac{1}{\rho}.$$

By induction, we obtain

$$x^{k+3} = x^2 - \frac{k+1}{\rho}, \quad \text{for all } k \geq 0,$$

which shows that x^{k+3} goes to $-\infty$ when k goes to infinity, and since $x^{k+2} = z^{k+2}$, similarly z^{k+3} goes to $-\infty$ when k goes to infinity.

52.5 Stopping Criteria

Going back to Inequality (A2),

$$p^{k+1} - p^* \leq -(\lambda^{k+1})^\top r^{k+1} - \rho(B(z^{k+1} - z^k))^\top(-r^{k+1} + B(z^{k+1} - z^*)), \quad (\text{A2})$$

using the fact that $Ax^* + Bz^* - c = 0$ and $r^{k+1} = Ax^{k+1} + Bz^{k+1} - c$, we have

$$\begin{aligned} -r^{k+1} + B(z^{k+1} - z^*) &= -Ax^{k+1} - Bz^{k+1} + c + B(z^{k+1} - z^*) \\ &= -Ax^{k+1} + c - Bz^* \\ &= -Ax^{k+1} + Ax^* = -A(x^{k+1} - x^*), \end{aligned}$$

so (A2) can be rewritten as

$$p^{k+1} - p^* \leq -(\lambda^{k+1})^\top r^{k+1} + \rho(B(z^{k+1} - z^k))^\top A(x^{k+1} - x^*),$$

or equivalently as

$$p^{k+1} - p^* \leq -(\lambda^{k+1})^\top r^{k+1} + (x^{k+1} - x^*)^\top \rho A^\top B(z^{k+1} - z^k). \quad (s_1)$$

We define the *dual residual* as

$$s^{k+1} = \rho A^\top B(z^{k+1} - z^k),$$

the quantity $r^{k+1} = Ax^{k+1} + Bz^{k+1} - c$ being the *primal residual*. Then (s₁) can be written as

$$p^{k+1} - p^* \leq -(\lambda^{k+1})^\top r^{k+1} + (x^{k+1} - x^*)^\top s^{k+1}. \quad (s)$$

Inequality (s) shows that when the residuals r^k and s^k are small, then p^k is close to p^* from below. Since x^* is unknown, we can't use this inequality, but if we have a guess that $\|x^k - x^*\| \leq d$, then using Cauchy-Schwarz we obtain

$$p^{k+1} - p^* \leq \|\lambda^{k+1}\| \|r^{k+1}\| + d \|s^{k+1}\|.$$

The above suggests that a reasonable termination criterion is that $\|r^k\|$ and $\|s^k\|$ should be small, namely that

$$\|r^k\| \leq \epsilon^{\text{pri}} \quad \text{and} \quad \|s^k\| \leq \epsilon^{\text{dual}},$$

for some chosen feasibility tolerances ϵ^{pri} and ϵ^{dual} . Further discussion for choosing these parameters can be found in Boyd et al. [28] (Section 3.3.1).

Various extensions and variations of ADMM are discussed in Boyd et al. [28] (Section 3.4). In order to accelerate convergence of the method, one may choose a different ρ at each step (say ρ^k), although proving the convergence of such a method may be difficult. If we assume that ρ^k becomes constant after a number of iterations, then the proof that we gave still applies. A simple scheme is this:

$$\rho^{k+1} = \begin{cases} \tau^{\text{incr}} \rho^k & \text{if } \|r^k\| > \mu \|s^k\| \\ \rho^k / \tau^{\text{decr}} & \text{if } \|s^k\| > \mu \|r^k\| \\ \rho^k & \text{otherwise,} \end{cases}$$

where $\tau^{\text{incr}} > 1$, $\tau^{\text{decr}} > 1$, and $\mu > 1$ are some chosen parameters. Again, we refer the interested reader to Boyd et al. [28] (Section 3.4).

52.6 Some Applications of ADMM

Structure in f , g , A , and B can often be exploited to yield more efficient methods for performing the x -update and the z -update. We focus on the x -update, but the discussion applies just as well to the z -update. Since z and λ are held constant during minimization over x , it is more convenient to use the scaled form of ADMM. Recall that

$$x^{k+1} = \arg \min_x \left(f(x) + (\rho/2) \|Ax + Bz^k - c + u^k\|_2^2 \right)$$

(here we use u instead of μ), so we can express the x -update step as

$$x^+ = \arg \min_x \left(f(x) + (\rho/2) \|Ax - v\|_2^2 \right),$$

with $v = -Bz^k + c - u^k$.

Example 52.7. A first simplification arises when $A = I$, in which case the x -update is

$$x^+ = \arg \min_x \left(f(x) + (\rho/2) \|x - v\|_2^2 \right) = \mathbf{prox}_{f,\rho}(v).$$

The map $v \mapsto \mathbf{prox}_{f,\rho}(v)$ is known as the *proximity operator of f with penalty ρ* . The above minimization is generally referred to as *proximal minimization*.

Example 52.8. When the function f is simple enough, the proximity operator can be computed analytically. This is the case in particular when $f = I_C$, the indicator function of a nonempty closed convex set C . In this case, it is easy to see that

$$x^+ = \arg \min_x (I_C(x) + (\rho/2) \|x - v\|_2^2) = \Pi_C(v),$$

the orthogonal projection of v onto C . In the special case where $C = \mathbb{R}_+^n$ (the first orthant), then

$$x^+ = (v)_+,$$

the vector obtained by setting the negative components of v to zero.

Example 52.9. A second case where simplifications arise is the case where f is a convex quadratic functional of the form

$$f(x) = \frac{1}{2}x^\top Px + q^\top x + r,$$

where P is an $n \times n$ symmetric positive semidefinite matrix, $q \in \mathbb{R}^n$ and $r \in \mathbb{R}$. In this case the gradient of the map

$$x \mapsto f(x) + (\rho/2) \|Ax - v\|_2^2 = \frac{1}{2}x^\top Px + q^\top x + r + \frac{\rho}{2}x^\top(A^\top A)x - \rho x^\top A^\top v + \frac{\rho}{2}v^\top v$$

is given by

$$(P + \rho A^\top A)x + q - \rho A^\top v,$$

and since A has rank n , the matrix $A^\top A$ is symmetric positive definite, so we get

$$x^+ = (P + \rho A^\top A)^{-1}(\rho A^\top v - q).$$

Methods from numerical linear algebra can be used to compute x^+ fairly efficiently; see Boyd et al. [28] (Section 4).

Example 52.10. A third case where simplifications arise is the variation of the previous case where f is a convex quadratic functional of the form

$$f(x) = \frac{1}{2}x^\top Px + q^\top x + r,$$

except that f is constrained by equality constraints $Cx = b$, as in Section 50.4, which means that $\text{dom}(f) = \{x \in \mathbb{R}^n \mid Cx = b\}$, and $A = I$. The x -minimization step consists in minimizing the function

$$J(x) = \frac{1}{2}x^\top Px + q^\top x + r + \frac{\rho}{2}x^\top x - \rho x^\top v + \frac{\rho}{2}v^\top v$$

subject to the constraint

$$Cx = b,$$

so by the results of Section 50.4, x^+ is a component of the solution of the KKT-system

$$\begin{pmatrix} P + \rho I & C^\top \\ C & 0 \end{pmatrix} \begin{pmatrix} x^+ \\ y \end{pmatrix} = \begin{pmatrix} -q + \rho v \\ b \end{pmatrix}.$$

The matrix $P + \rho I$ is symmetric positive definite, so the KKT-matrix is invertible.

We can now describe how ADMM is used to solve two common problems of convex optimization.

- (1) *Minimization of a proper closed convex function f over a closed convex set C in \mathbb{R}^n .*

This is the following problem

$$\begin{aligned} & \text{minimize} && f(x) \\ & \text{subject to} && x \in C, \end{aligned}$$

which can be rewritten in AADM form as

$$\begin{aligned} & \text{minimize} && f(x) + I_C(z) \\ & \text{subject to} && x - z = 0. \end{aligned}$$

Using the scaled dual variable $u = \lambda/\rho$, the augmented Lagrangian is

$$L_\rho(x, z, u) = f(x) + I_C(z) + \frac{\rho}{2} \|x - z + u\|_2^2 - \frac{\rho}{2} \|u\|^2.$$

In view of Example 52.8, the scaled form of ADMM for this problem is

$$\begin{aligned} x^{k+1} &= \arg \min_x \left(f(x) + (\rho/2) \|x - z^k + u^k\|_2^2 \right) \\ z^{k+1} &= \Pi_C(x^{k+1} + u^k) \\ u^{k+1} &= u^k + x^{k+1} - z^{k+1}. \end{aligned}$$

The x -update involves evaluating a proximal operator. Note that the function f need not be differentiable. Of course, these minimizations depend on having efficient computational procedures for the proximal operator and the projection operator.

- (2) *Quadratic Programming.* Here the problem is

$$\begin{aligned} & \text{minimize} && \frac{1}{2} x^\top P x + q^\top x + r \\ & \text{subject to} && Ax = b, \quad x \geq 0, \end{aligned}$$

where P is an $n \times n$ symmetric positive semidefinite matrix, $q \in \mathbb{R}^n$, $r \in \mathbb{R}$, and A is an $m \times n$ matrix of rank m .

The above program is converted in ADMM form as follows:

$$\begin{aligned} & \text{minimize } f(x) + g(z) \\ & \text{subject to } x - z = 0, \end{aligned}$$

with

$$f(x) = \frac{1}{2}x^\top Px + q^\top x + r, \quad \text{dom}(f) = \{x \in \mathbb{R}^n \mid Ax = b\},$$

and

$$g = I_{\mathbb{R}_+^n},$$

the indicator function of the positive orthant \mathbb{R}_+^n . In view of Example 52.8 and Example 52.10, the scaled form of ADMM consists of the following steps:

$$\begin{aligned} x^{k+1} &= \arg \min_x \left(f(x) + (\rho/2) \|x - z^k + u^k\|_2^2 \right) \\ z^{k+1} &= (x^{k+1} + u^k)_+ \\ u^{k+1} &= u^k + x^{k+1} - z^{k+1}. \end{aligned}$$

The x -update involves solving the KKT equations

$$\begin{pmatrix} P + \rho I & A^\top \\ A & 0 \end{pmatrix} \begin{pmatrix} x^{k+1} \\ y \end{pmatrix} = \begin{pmatrix} -q + \rho(z^k - u^k) \\ b \end{pmatrix}.$$

This is an important example because it provides one of the best methods for solving quadratic problems, in particular, the SVM problems discussed in Chapter 54.

We programmed the above method in Matlab as the function `qsolve1`, see Appendix B, Section B.1. Here are two examples.

Example 52.11. Consider the quadratic program for which

$$\begin{aligned} P_1 &= \begin{pmatrix} 4 & 1 & 0 \\ 1 & 4 & 1 \\ 0 & 1 & 4 \end{pmatrix} & q_1 &= -\begin{pmatrix} 4 \\ 4 \\ 4 \end{pmatrix} \\ A_1 &= \begin{pmatrix} 1 & 1 & -1 \\ 1 & -1 & -1 \end{pmatrix} & b_1 &= \begin{pmatrix} 0 \\ 0 \end{pmatrix}. \end{aligned}$$

We see immediately that the constraints

$$\begin{aligned} x + y - z &= 0 \\ x - y - z &= 0 \end{aligned}$$

imply that $z = x$ and $y = 0$. Then it is easy using calculus to find that the unique minimum is given by $(x, y, z) = (1, 0, 1)$. Running `qsolve1` on P_1, q_1, A_1, b_1 with $\rho = 10$, $tolr = tols = 10^{-12}$ and $iternum = 10000$, we find that after 83 iterations the primal and the dual residuals are less than 10^{-12} , and we get

$$(x, y, z) = (1.000000000000149, 0.000000000000000, 1.000000000000148).$$

Example 52.12. Consider the quadratic program for which

$$P_2 = \begin{pmatrix} 4 & 1 & 0 & 0 \\ 1 & 4 & 1 & 0 \\ 0 & 1 & 4 & 1 \\ 0 & 0 & 1 & 4 \end{pmatrix} \quad q_2 = -\begin{pmatrix} 4 \\ 4 \\ 4 \\ 4 \end{pmatrix}$$

$$A_2 = \begin{pmatrix} 1 & 1 & -1 & 0 \\ 1 & -1 & -1 & 0 \end{pmatrix} \quad b_2 = \begin{pmatrix} 0 \\ 0 \end{pmatrix}.$$

Again, we see immediately that the constraints imply that $z = x$ and $y = 0$. Then it is easy using calculus to find that the unique minimum is given by $(x, y, z) = (28/31, 0, 28/31, 24/31)$. Running `qsolve1` on P_2, q_2, A_2, b_2 with $\rho = 10$, $\text{tolr} = \text{tol} = 10^{-12}$ and $\text{iternum} = 10000$, we find that after 95 iterations the primal and the dual residuals are less than 10^{-12} , and we get

$$(x, y, z, t) = (0.903225806451495, 0.000000000000000, 0.903225806451495, 0.774193548387264),$$

which agrees with the answer found earlier up to 11 decimals.

As an illustration of the wide range of applications of ADMM we show in the next section how to solve the hard margin SVM (SVM_{h2}) discussed in Section 50.6.

52.7 Solving Hard Margin (SVM_{h2}) Using ADMM

Recall that we would like to solve the following optimization problem (see Section 50.6):

Hard margin SVM (SVM_{h2}):

$$\begin{aligned} & \text{minimize} \quad \frac{1}{2} \|w\|^2 \\ & \text{subject to} \\ & \quad w^\top u_i - b \geq 1 \quad i = 1, \dots, p \\ & \quad -w^\top v_j + b \geq 1 \quad j = 1, \dots, q. \end{aligned}$$

The margin is $\delta = 1/\|w\|$. The separating hyperplane $H_{w,b}$ is the hyperplane of equation $w^\top x - b = 0$, and the margin hyperplanes are the hyperplanes $H_{w,b+1}$ (the blue hyperplane) of equation $w^\top x - b - 1 = 0$ and $H_{w,b-1}$ (the red hyperplane) of equation $w^\top x - b + 1 = 0$. The dual program derived in Section 50.10 is the following program:

Dual of the Hard margin SVM (SVM_{h2}):

$$\text{minimize} \quad \frac{1}{2} (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - (\lambda^\top \mu^\top) \mathbf{1}_{p+q}$$

subject to

$$\sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j = 0$$

$$\lambda \geq 0, \mu \geq 0,$$

where X is the $n \times (p + q)$ matrix given by

$$X = (-u_1 \ \cdots \ -u_p \ v_1 \ \cdots \ v_q).$$

Then w is determined as follows:

$$w = -X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = \sum_{i=1}^p \lambda_i u_i - \sum_{j=1}^q \mu_j v_j.$$

To solve the dual using ADMM we need to determine the matrices P, q, A and c as in Section 52.6(2). We renamed b as c to avoid a clash since b is already used. We have

$$P = X^\top X, \quad q = -\mathbf{1}_{p+q},$$

and since the only constraint is

$$\sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j = 0,$$

the matrix A is the $1 \times (p + q)$ row vector

$$A = (\mathbf{1}_p^\top \ -\mathbf{1}_q^\top),$$

and the right-hand side c is the scalar

$$c = 0.$$

Obviously the matrix A has rank 1. We obtain b using any i_0 such that $\lambda_{i_0} > 0$ and any j_0 such that $\mu_{j_0} > 0$. Since the corresponding constraints are active, we have

$$w^\top u_{i_0} - b = 1, \quad -w^\top v_{j_0} + b = 1,$$

so we obtain

$$b = w^\top (u_{i_0} + v_{j_0}) / 2.$$

For improved numerical stability, we can average over the sets of indices defined as $I_{\lambda>0} = \{i \in \{1, \dots, p\} \mid \lambda_i > 0\}$ and $I_{\mu>0} = \{j \in \{1, \dots, q\} \mid \mu_j > 0\}$. We obtain

$$b = w^\top \left(\left(\sum_{i \in I_{\lambda>0}} u_i \right) / |I_{\lambda>0}| + \left(\sum_{j \in I_{\mu>0}} v_j \right) / |I_{\mu>0}| \right) / 2.$$

The Matlab programs implementing the above method are given in Appendix B, Section B.1. This should convince the reader that there is very little gap between theory and practice, although it is quite consuming to tune the tolerance parameters needed to deal with floating-point arithmetic.

Figure 52.5 shows the result of running the Matlab program implementing the above method using ADMM on two sets of points of 50 points each generated at random using the following Matlab code.

```
u14 = 10.1*randn(2,50)+18;
v14 = -10.1*randn(2,50)-18;
```

The function `SVMhard2` is called with $\rho = 10$ as follows

```
[lamb,mu,w] = SVMhard2(10,u14,v14)
```

and produces the output shown in Figure 52.5. Observe that there is one blue support vector and two red support vectors.

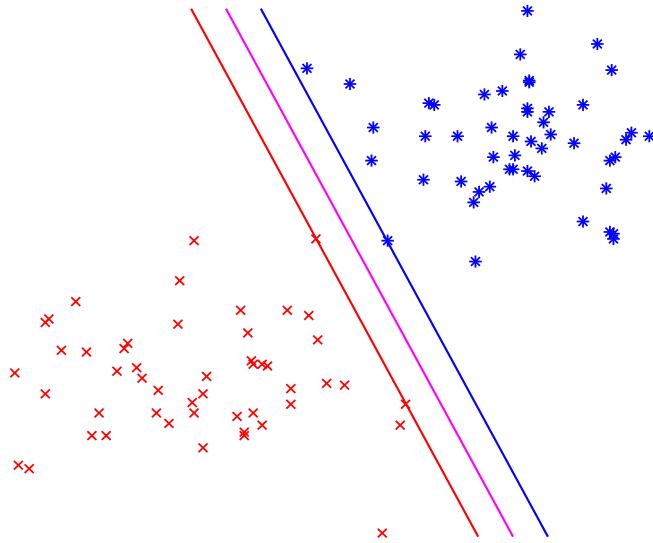

Figure 52.5: An example of hard margin SVM.

52.8 Applications of ADMM to ℓ^1 -Norm Problems

Another important application of ADMM is to ℓ^1 -norm minimization problems, especially lasso minimization, discussed below and in Section 55.4. This involves the special case of

ADMM where $f(x) = \tau \|x\|_1$ and $A = I$. In particular, in the one-dimensional case, we need to solve the minimization problem: find

$$x^* = \arg \min_x (\tau|x| + (\rho/2)(x - v)^2),$$

with $x, v \in \mathbb{R}$, and $\rho, \tau > 0$. Let $c = \tau/\rho$ and write

$$f(x) = \frac{\tau}{2c} (2c|x| + (x - v)^2).$$

Minimizing f over x is equivalent to minimizing

$$g(x) = 2c|x| + (x - v)^2 = 2c|x| + x^2 - 2xv + v^2,$$

which is equivalent to minimizing

$$h(x) = x^2 + 2(c|x| - xv)$$

over x . If $x \geq 0$, then

$$h(x) = x^2 + 2(cx - xv) = x^2 + 2(c - v)x = (x - (v - c))^2 - (v - c)^2.$$

If $v - c > 0$, that is, $v > c$, since $x \geq 0$, the function $x \mapsto (x - (v - c))^2$ has a minimum for $x = v - c > 0$, else if $v - c \leq 0$, then the function $x \mapsto (x - (v - c))^2$ has a minimum for $x = 0$.

If $x \leq 0$, then

$$h(x) = x^2 + 2(-cx - xv) = x^2 - 2(c + v)x = (x - (v + c))^2 - (v + c)^2.$$

if $v + c < 0$, that is, $v < -c$, since $x \leq 0$, the function $x \mapsto (x - (v + c))^2$ has a minimum for $x = v + c$, else if $v + c \geq 0$, then the function $x \mapsto (x - (v + c))^2$ has a minimum for $x = 0$.

In summary, $\inf_x h(x)$ is the function of v given by

$$S_c(v) = \begin{cases} v - c & \text{if } v > c \\ 0 & \text{if } |v| \leq c \\ v + c & \text{if } v < -c. \end{cases}$$

The function S_c is known as a *soft thresholding operator*. The graph of S_c shown in Figure 52.6.

One can check that

$$S_c(v) = (v - c)_+ - (-v - c)_+,$$

and also

$$S_c(v) = (1 - c/|v|)_+ v, \quad v \neq 0,$$

which shows that S_c is a *shrinkage operator* (it moves a point toward zero).

The operator S_c is extended to vectors in \mathbb{R}^n component wise, that is, if $x = (x_1, \dots, x_n)$, then

$$S_c(x) = (S_c(x_1), \dots, S_c(x_n)).$$

We now consider several ℓ^1 -norm problems.

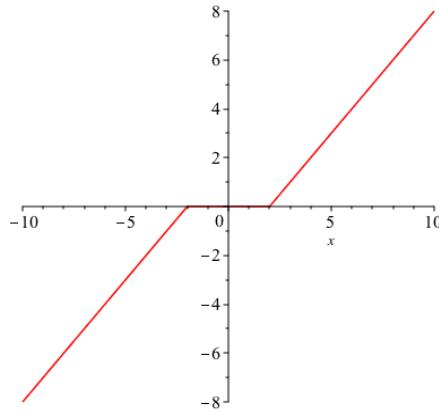

Figure 52.6: The graph of S_c (when $c = 2$).

(1) *Least absolute deviation.*

This is the problem of minimizing $\|Ax - b\|_1$, rather than $\|Ax - b\|_2$. Least absolute deviation is more robust than least squares fit because it deals better with outliers. The problem can be formulated in ADMM form as follows:

$$\begin{aligned} & \text{minimize} && \|z\|_1 \\ & \text{subject to} && Ax - z = b, \end{aligned}$$

with $f = 0$ and $g = \|\cdot\|_1$. As usual, we assume that A is an $m \times n$ matrix of rank n , so that $A^\top A$ is invertible. ADMM (in scaled form) can be expressed as

$$\begin{aligned} x^{k+1} &= (A^\top A)^{-1} A^\top (b + z^k - u^k) \\ z^{k+1} &= S_{1/\rho}(Ax^{k+1} - b + u^k) \\ u^{k+1} &= u^k + Ax^{k+1} - z^{k+1} - b. \end{aligned}$$

(2) *Basis pursuit.*

This is the following minimization problem:

$$\begin{aligned} & \text{minimize} && \|x\|_1 \\ & \text{subject to} && Ax = b, \end{aligned}$$

where A is an $m \times n$ matrix of rank $m < n$, and $b \in \mathbb{R}^m$, $x \in \mathbb{R}^n$. The problem is to find a sparse solution to an underdetermined linear system, which means a solution x with many zero coordinates. This problem plays a central role in compressed sensing and statistical signal processing.

Basis pursuit can be expressed in ADMM form as the problem

$$\begin{aligned} & \text{minimize} && I_C(x) + \|z\|_1 \\ & \text{subject to} && x - z = 0, \end{aligned}$$

with $C = \{x \in \mathbb{R}^n \mid Ax = b\}$. It is easy to see that the ADMM procedure (in scaled form) is

$$\begin{aligned} x^{k+1} &= \Pi_C(z^k - u^k) \\ z^{k+1} &= S_{1/\rho}(x^{k+1} + u^k) \\ u^{k+1} &= u^k + x^{k+1} - z^{k+1}, \end{aligned}$$

where Π_C is the orthogonal projection onto the subspace C . In fact, it is not hard to show that

$$x^{k+1} = (I - A^\top (AA^\top)^{-1}A)(z^k - u^k) + A^\top (AA^\top)^{-1}b.$$

In some sense, an ℓ^1 -minimization problem is reduced to a sequence of ℓ^2 -norm problems. There are ways of improving the efficiency of the method; see Boyd et al. [28] (Section 6.2)

(3) General ℓ^1 -regularized loss minimization.

This is the following minimization problem:

$$\text{minimize } l(x) + \tau \|x\|_1,$$

where l is any proper closed and convex loss function, and $\tau > 0$. We convert the problem to the ADMM problem:

$$\begin{aligned} & \text{minimize} && l(x) + \tau \|z\|_1 \\ & \text{subject to} && x - z = 0. \end{aligned}$$

The ADMM procedure (in scaled form) is

$$\begin{aligned} x^{k+1} &= \arg \min_x \left(l(x) + (\rho/2) \|x - z^k + u^k\|_2^2 \right) \\ z^{k+1} &= S_{\tau/\rho}(x^{k+1} + u^k) \\ u^{k+1} &= u^k + x^{k+1} - z^{k+1}. \end{aligned}$$

The x -update is a proximal operator evaluation. In general, one needs to apply a numerical procedure to compute x^{k+1} , for example, a version of Newton's method. The special case where $l(x) = (1/2) \|Ax - b\|_2^2$ is particularly important.

(4) *Lasso regularization.*

This is the following minimization problem:

$$\text{minimize} \quad (1/2) \|Ax - b\|_2^2 + \tau \|x\|_1.$$

This is a linear regression with the regularizing term $\tau \|x\|_1$ instead of $\tau \|x\|_2$, to encourage a sparse solution. This method was first proposed by Tibshirani around 1996, under the name *lasso*, which stands for “least absolute selection and shrinkage operator.” This method is also known as ℓ^1 -regularized regression, but this is not as cute as “lasso,” which is used predominantly. This method is discussed extensively in Hastie, Tibshirani, and Wainwright [89].

The lasso minimization is converted to the following problem in ADMM form:

$$\begin{aligned} \text{minimize} \quad & \|Ax - b\|_2^2 + \tau \|z\|_1 \\ \text{subject to} \quad & x - z = 0. \end{aligned}$$

Then the ADMM procedure (in scaled form) is

$$\begin{aligned} x^{k+1} &= (A^\top A + \rho I)^{-1}(A^\top b + \rho(z^k - u^k)) \\ z^{k+1} &= S_{\tau/\rho}(x^{k+1} + u^k) \\ u^{k+1} &= u^k + x^{k+1} - z^{k+1}. \end{aligned}$$

Since $\rho > 0$, the matrix $A^\top A + \rho I$ is symmetric positive definite. Note that the x -update looks like a *ridge regression step* (see Section 55.1).

There are various generalizations of lasso.

(5) *Generalized Lasso regularization.*

This is the following minimization problem:

$$\text{minimize} \quad (1/2) \|Ax - b\|_2^2 + \tau \|Fx\|_1,$$

where A is an $m \times n$ matrix, F is a $p \times n$ matrix, and either A has rank n or F has rank n . This problem is converted to the ADMM problem

$$\begin{aligned} \text{minimize} \quad & \|Ax - b\|_2^2 + \tau \|z\|_1 \\ \text{subject to} \quad & Fx - z = 0, \end{aligned}$$

and the corresponding ADMM procedure (in scaled form) is

$$\begin{aligned} x^{k+1} &= (A^\top A + \rho F^\top F)^{-1}(A^\top b + \rho F^\top(z^k - u^k)) \\ z^{k+1} &= S_{\tau/\rho}(Fx^{k+1} + u^k) \\ u^{k+1} &= u^k + Fx^{k+1} - z^{k+1}. \end{aligned}$$

(6) *Group Lasso.*

This is a generalization of (3). Here we assume that x is split as $x = (x_1, \dots, x_N)$, with $x_i \in \mathbb{R}^{n_i}$ and $n_1 + \dots + n_N = n$, and the regularizing term $\|x\|_1$ is replaced by $\sum_{i=1}^N \|x_i\|_2$. When $n_i = 1$, this reduces to (3). The z -update of the ADMM procedure needs to be modified. We define the soft thresholding operator $\mathcal{S}_c: \mathbb{R}^m \rightarrow \mathbb{R}^m$ given by

$$\mathcal{S}_c(v) = \left(1 - \frac{c}{\|v\|_2}\right)_+ v,$$

with $\mathcal{S}_c(0) = 0$. Then the z -update consists of the N updates

$$z_i^{k+1} = \mathcal{S}_{\tau/\rho}(x_i^{k+1} + u^k), \quad i = 1, \dots, N.$$

The method can be extended to deal with overlapping groups; see Boyd et al. [28] (Section 6.4).

There are many more applications of ADMM discussed in Boyd et al. [28], including consensus and sharing. See also Strang [171] for a brief overview.

52.9 Summary

The main concepts and results of this chapter are listed below:

- Dual ascent.
- Augmented Lagrangian.
- Penalty parameter.
- Method of multipliers.
- ADMM (alternating direction method of multipliers).
- x -update, z -update, λ -update.
- Scaled form of ADMM.
- Residual, dual residual.
- Stopping criteria.
- Proximity operator, proximal minimization.
- Quadratic programming.
- KKT equations.

- Soft thresholding operator.
- Shrinkage operator.
- Least absolute deviation.
- Basis pursuit.
- General ℓ^1 -regularized loss minimization.
- Lasso regularization.
- Generalized lasso regularization.
- Group lasso.

52.10 Problems

Problem 52.1. In the method of multipliers described in Section 52.2, prove that choosing $\alpha^k = \rho$ guarantees that (u^{k+1}, λ^{k+1}) satisfies the equation

$$\nabla J_{u^{k+1}} + A^\top \lambda^{k+1} = 0.$$

Problem 52.2. Prove that the Inequality (A1) follows from the Inequalities (A2) and (A3) (see the proof of Theorem 52.1). For help consult Appendix A of Boyd et al. [28].

Problem 52.3. Consider Example 52.8. Prove that if $f = I_C$, the indicator function of a nonempty closed convex set C , then

$$x^+ = \arg \min_x (I_C(x) + (\rho/2) \|x - v\|_2^2) = \Pi_C(v),$$

the orthogonal projection of v onto C . In the special case where $C = \mathbb{R}_+^n$ (the first orthant), then

$$x^+ = (v)_+,$$

the vector obtained by setting the negative components of v to zero.

Problem 52.4. Prove that the soft thresholding operator S_c from Section 52.8 satisfies the equations

$$S_c(v) = (v - c)_+ - (-v - c)_+,$$

and

$$S_c(v) = (1 - c/|v|)_+ v, \quad v \neq 0.$$

Problem 52.5. Rederive the formula

$$S_c(v) = \begin{cases} v - c & \text{if } v > c \\ 0 & \text{if } |v| \leq c \\ v + c & \text{if } v < -c \end{cases}$$

using subgradients.

Problem 52.6. In basis pursuit (see Section 52.8 (2)) prove that

$$x^{k+1} = (I - A^\top (AA^\top)^{-1}A)(z^k - u^k) + A^\top (AA^\top)^{-1}b.$$

Problem 52.7. Implement (in **Matlab**) ADMM applied to lasso regularization as described in Section 52.6 (4). The stopping criterion should be based on feasibility tolerances ϵ^{pri} and ϵ^{dual} , say 10^{-4} , and on a maximum number of iteration steps, say 10000. There is a build in **Matlab** function **wthresh** implementing soft thresholding. You may use the **Matlab** command **randn** to create a random data set X and a random response vector y (see the help menu in **Matlab** under **lasso**). Try various values of ρ and τ . You will observe that the choice of ρ greatly affects the rate of convergence of the procedure.

Part IX

Applications to Machine Learning

Chapter 53

Positive Definite Kernels

This chapter is an introduction to positive definite kernels and the use of kernel functions in machine learning.

Let X be a nonempty set. If the set X represents a set of highly nonlinear data, it may be advantageous to map X into a space F of much higher dimension called the *feature space*, using a function $\varphi: X \rightarrow F$ called a *feature map*. This idea is that φ “unwinds” the description of the objects in F in an attempt to make it linear. The space F is usually a vector space equipped with an inner product $\langle -, - \rangle$. If F is infinite dimensional, then we assume that it is a Hilbert space.

Many algorithms that analyze or classify data make use of the inner products $\langle \varphi(x), \varphi(y) \rangle$, where $x, y \in X$. These algorithms make use of the function $\kappa: X \times X \rightarrow \mathbb{C}$ given by

$$\kappa(x, y) = \langle \varphi(x), \varphi(y) \rangle, \quad x, y \in X,$$

called a *kernel function*.

The kernel trick is to pretend that we have a feature embedding $\varphi: X \rightarrow F$ (actually unknown), but to only use inner products $\langle \varphi(x), \varphi(y) \rangle$ that can be evaluated using the original data through the known kernel function κ . It turns out that the functions of the form κ as above can be defined in terms of a condition which is reminiscent of positive semidefinite matrices (see Definition 53.2). Furthermore, every function satisfying Definition 53.2 arises from a suitable feature map into a Hilbert space; see Theorem 53.8.

We illustrate the kernel methods on kernel PCA (see Section 53.4).

53.1 Feature Maps and Kernel Functions

Definition 53.1. Let X be a nonempty set, let H be a (complex) Hilbert space, and let $\varphi: X \rightarrow H$ be a function called a *feature map*. The function $\kappa: X \times X \rightarrow \mathbb{C}$ given by

$$\kappa(x, y) = \langle \varphi(x), \varphi(y) \rangle, \quad x, y \in X,$$

is called a *kernel function*.

Remark: A *feature map* is often called a *feature embedding*, but this terminology is a bit misleading because it suggests that such a map is injective, which is not necessarily the case. Unfortunately this terminology is used by most people.

Example 53.1. Suppose we have two feature maps $\varphi_1: X \rightarrow \mathbb{R}^{n_1}$ and $\varphi_2: X \rightarrow \mathbb{R}^{n_2}$, and let $\kappa_1(x, y) = \langle \varphi_1(x), \varphi_1(y) \rangle$ and $\kappa_2(x, y) = \langle \varphi_2(x), \varphi_2(y) \rangle$ be the corresponding kernel functions (where $\langle -, - \rangle$ is the standard inner product on \mathbb{R}^n). Define the feature map $\varphi: X \rightarrow \mathbb{R}^{n_1+n_2}$ by

$$\varphi(x) = (\varphi_1(x), \varphi_2(x)),$$

an $(n_1 + n_2)$ -tuple. We have

$$\begin{aligned}\langle \varphi(x), \varphi(y) \rangle &= \langle (\varphi_1(x), \varphi_2(x)), (\varphi_1(y), \varphi_2(y)) \rangle = \langle \varphi_1(x), \varphi_1(y) \rangle + \langle \varphi_2(x), \varphi_2(y) \rangle \\ &= \kappa_1(x, y) + \kappa_2(x, y),\end{aligned}$$

which shows that the map κ given by

$$\kappa(x, y) = \kappa_1(x, y) + \kappa_2(x, y)$$

is the kernel function corresponding to the feature map $\varphi: X \rightarrow \mathbb{R}^{n_1+n_2}$.

Example 53.2. Let X be a subset of \mathbb{R}^2 , and let $\varphi_1: X \rightarrow \mathbb{R}^3$ be the map given by

$$\varphi_1(x_1, x_2) = (x_1^2, x_2^2, \sqrt{2}x_1x_2).$$

Figure 53.1 illustrates $\varphi_1: X \rightarrow \mathbb{R}^3$ when $X = \{(x_1, x_2) \mid -10 \leq x_1 \leq 10, -10 \leq x_2 \leq 10\}$.

Observe that linear relations in the feature space $H = \mathbb{R}^3$ correspond to quadratic relations in the input space (of data). We have

$$\begin{aligned}\langle \varphi_1(x), \varphi_1(y) \rangle &= \langle (x_1^2, x_2^2, \sqrt{2}x_1x_2), (y_1^2, y_2^2, \sqrt{2}y_1y_2) \rangle \\ &= x_1^2y_1^2 + x_2^2y_2^2 + 2x_1x_2y_1y_2 \\ &= (x_1y_1 + x_2y_2)^2 = \langle x, y \rangle^2,\end{aligned}$$

where $\langle x, y \rangle$ is the usual inner product on \mathbb{R}^2 . Hence the function

$$\kappa(x, y) = \langle x, y \rangle^2$$

is a kernel function associated with the feature space \mathbb{R}^3 .

If we now consider the map $\varphi_2: X \rightarrow \mathbb{R}^4$ given by

$$\varphi_2(x_1, x_2) = (x_1^2, x_2^2, x_1x_2, x_1x_2),$$

we check immediately that

$$\langle \varphi_2(x), \varphi_2(y) \rangle = \kappa(x, y) = \langle x, y \rangle^2,$$

which shows that the same kernel can arise from different maps into different feature spaces.

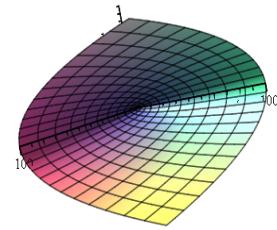

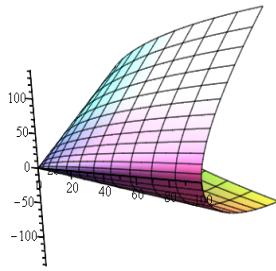

Figure 53.1: The parametric surface $\varphi_1(x_1, x_2) = (x_1^2, x_2^2, \sqrt{2}x_1x_2)$ where $-10 \leq x_1 \leq 10$ and $-10 \leq x_2 \leq 10$.

Example 53.3. Example 53.2 can be generalized as follows. Suppose we have a feature map $\varphi_1: X \rightarrow \mathbb{R}^n$ and let $\kappa_1(x, y) = \langle \varphi_1(x), \varphi_1(y) \rangle$ be the corresponding kernel function (where $\langle -, - \rangle$ is the standard inner product on \mathbb{R}^n). Define the feature map $\varphi: X \rightarrow \mathbb{R}^n \times \mathbb{R}^n$ by its n^2 components

$$\varphi(x)_{(i,j)} = (\varphi_1(x))_i(\varphi_1(x))_j, \quad 1 \leq i, j \leq n,$$

with the inner product on $\mathbb{R}^n \times \mathbb{R}^n$ given by

$$\langle u, v \rangle = \sum_{i,j=1}^n u_{(i,j)}v_{(i,j)}.$$

Then we have

$$\begin{aligned} \langle \varphi(x), \varphi(y) \rangle &= \sum_{i,j=1}^n \varphi_{(i,j)}(x)\varphi_{(i,j)}(y) \\ &= \sum_{i,j=1}^n (\varphi_1(x))_i(\varphi_1(x))_j(\varphi_1(y))_i(\varphi_1(y))_j \\ &= \sum_{i=1}^n (\varphi_1(x))_i(\varphi_1(y))_i \sum_{j=1}^n (\varphi_1(x))_j(\varphi_1(y))_j \\ &= (\kappa_1(x, y))^2. \end{aligned}$$

Thus the map κ given by $\kappa(x, y) = (\kappa_1(x, y))^2$ is a kernel map associated with the feature map $\varphi: X \rightarrow \mathbb{R}^n \times \mathbb{R}^n$. The feature map φ is a direct generalization of the feature map φ_2 of Example 53.2.

The above argument is immediately adapted to show that if $\varphi_1: X \rightarrow \mathbb{R}^{n_1}$ and $\varphi_2: X \rightarrow \mathbb{R}^{n_2}$ are two feature maps and if $\kappa_1(x, y) = \langle \varphi_1(x), \varphi_1(y) \rangle$ and $\kappa_2(x, y) = \langle \varphi_2(x), \varphi_2(y) \rangle$ are the corresponding kernel functions, then the map defined by

$$\kappa(x, y) = \kappa_1(x, y)\kappa_2(x, y)$$

is a kernel function for the feature space $\mathbb{R}^{n_1} \times \mathbb{R}^{n_2}$ and the feature map

$$\varphi(x)_{(i,j)} = (\varphi_1(x))_i(\varphi_2(x))_j, \quad 1 \leq i \leq n_1, 1 \leq j \leq n_2.$$

Example 53.4. Note that the feature map $\varphi: X \rightarrow \mathbb{R}^n \times \mathbb{R}^n$ is not very economical because if $i \neq j$ then the components $\varphi_{(i,j)}(x)$ and $\varphi_{(j,i)}(x)$ are both equal to $(\varphi_1(x))_i(\varphi_1(x))_j$. Therefore we can define the more economical embedding $\varphi': X \rightarrow \mathbb{R}^{\binom{n+1}{2}}$ given by

$$\varphi'(x)_{(i,j)} = \begin{cases} (\varphi_1(x))_i^2 & i = j, \\ \sqrt{2}(\varphi_1(x))_i(\varphi_1(x))_j & i < j, \end{cases}$$

where the pairs (i, j) with $1 \leq i \leq j \leq n$ are ordered lexicographically. The feature map φ' is a direct generalization of the feature map φ_1 of Example 53.2.

Observe that φ' can also be defined in the following way which makes it easier to come up with the generalization to any power:

$$\varphi'_{(i_1, \dots, i_n)}(x) = \binom{2}{i_1 \dots i_n}^{1/2} (\varphi_1(x))_1^{i_1} (\varphi_1(x))_1^{i_2} \cdots (\varphi_1(x))_1^{i_n}, \quad i_1 + i_2 + \cdots + i_n = 2, i_j \in \mathbb{N},$$

where the n -tuples (i_1, \dots, i_n) are ordered lexicographically. Recall that for any $m \geq 1$ and any $(i_1, \dots, i_n) \in \mathbb{N}^m$ such that $i_1 + i_2 + \cdots + i_n = m$, we have

$$\binom{m}{i_1 \dots i_n} = \frac{m!}{i_1! \cdots i_n!}.$$

More generally, for any $m \geq 2$, using the multinomial theorem, we can define a feature embedding $\varphi: X \rightarrow \mathbb{R}^{\binom{n+m-1}{m}}$ defining the kernel function κ given by $\kappa(x, y) = (\kappa_1(x, y))^m$, with φ given by

$$\varphi_{(i_1, \dots, i_n)}(x) = \binom{m}{i_1 \dots i_n}^{1/2} (\varphi_1(x))_1^{i_1} (\varphi_1(x))_1^{i_2} \cdots (\varphi_1(x))_1^{i_n}, \quad i_1 + i_2 + \cdots + i_n = m, i_j \in \mathbb{N},$$

where the n -tuples (i_1, \dots, i_n) are ordered lexicographically.

Example 53.5. For any positive real constant $R > 0$, the constant function $\kappa(x, y) = R$ is a kernel function corresponding to the feature map $\varphi: X \rightarrow \mathbb{R}$ given by $\varphi(x, y) = \sqrt{R}$.

By definition, the function $\kappa'_1: \mathbb{R}^n \rightarrow \mathbb{R}$ given by $\kappa'_1(x, y) = \langle x, y \rangle$ is a kernel function (the feature map is the identity map from \mathbb{R}^n to itself). We just saw that for any positive real constant $R > 0$, the constant $\kappa'_2(x, y) = R$ is a kernel function. By Example 53.1, the function $\kappa'_3(x, y) = \kappa'_1(x, y) + \kappa'_2(x, y)$ is a kernel function, and for any integer $d \geq 1$, by Example 53.4, the function κ_d given by

$$\kappa_d(x, y) = (\kappa'_3(x, y))^d = (\langle x, y \rangle + R)^d,$$

is a kernel function on \mathbb{R}^n . By the binomial formula,

$$\kappa_d(x, y) = \sum_{m=0}^d R^{d-m} \langle x, y \rangle^m.$$

By Example 53.1, the feature map of this kernel function is the concatenation of the features of the $d+1$ kernel maps $R^{d-m} \langle x, y \rangle^m$. By Example 53.3, the components of the feature map of the kernel map $R^{d-m} \langle x, y \rangle^m$ are reweightings of the functions

$$\varphi_{(i_1, \dots, i_n)}(x) = x_1^{i_1} x_2^{i_2} \cdots x_n^{i_n}, \quad i_1 + i_2 + \cdots + i_n = m,$$

with $(i_1, \dots, i_n) \in \mathbb{N}^n$. Thus the components of the feature map of the kernel function κ_d are reweightings of the functions

$$\varphi_{(i_1, \dots, i_n)}(x) = x_1^{i_1} x_2^{i_2} \cdots x_n^{i_n}, \quad i_1 + i_2 + \cdots + i_n \leq d,$$

with $(i_1, \dots, i_n) \in \mathbb{N}^n$. It is easy to see that the dimension of this feature space is $\binom{m+d}{d}$.

There are a number of variations of the polynomial kernel κ_d ; all-subsets embedding kernels, ANOVA kernels; see Shawe-Taylor and Christianini [159], Chapter III.

In the next example the set X is not a vector space.

Example 53.6. Let D be a finite set and let $X = 2^D$ be its power set. If $|D| = n$, let $H = \mathbb{R}^X \cong \mathbb{R}^{2^n}$. We are assuming that the subsets of D are enumerated in some fashion so that each coordinate of \mathbb{R}^{2^n} corresponds to one of these subsets. For example, if $D = \{1, 2, 3, 4\}$, let

$$\begin{array}{llll} U_1 = \emptyset & U_2 = \{1\} & U_3 = \{2\} & U_4 = \{3\} \\ U_5 = \{4\} & U_6 = \{1, 2\} & U_7 = \{1, 3\} & U_8 = \{1, 4\} \\ U_9 = \{2, 3\} & U_{10} = \{2, 4\} & U_{11} = \{3, 4\} & U_{12} = \{1, 2, 3\} \\ U_{13} = \{1, 2, 4\} & U_{14} = \{1, 3, 4\} & U_{15} = \{2, 3, 4\} & U_{16} = \{1, 2, 3, 4\}. \end{array}$$

Let $\varphi: X \rightarrow H$ be the feature map defined as follows: for any subsets $A, U \in X$,

$$\varphi(A)_U = \begin{cases} 1 & \text{if } U \subseteq A \\ 0 & \text{otherwise.} \end{cases}$$

For example, if $A_1 = \{1, 2, 3\}$, we obtain the vector

$$\varphi(\{1, 2, 3\}) = (1, 1, 1, 1, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0),$$

and if $A_2 = \{2, 3, 4\}$, we obtain the vector

$$\varphi(\{2, 3, 4\}) = (1, 0, 1, 1, 1, 0, 0, 0, 1, 1, 1, 0, 0, 0, 1, 0).$$

For any two subsets A_1 and A_2 of D , it is easy to check that

$$\langle \varphi(A_1), \varphi(A_2) \rangle = 2^{|A_1 \cap A_2|},$$

the number of common subsets of A_1 and A_2 . For example, $A_1 \cap A_2 = \{2, 3\}$, and

$$\langle \varphi(A_1), \varphi(A_2) \rangle = 4.$$

Therefore, the function $\kappa: X \times X \rightarrow \mathbb{R}$ given by

$$\kappa(A_1, A_2) = 2^{|A_1 \cap A_2|}, \quad A_1, A_2 \subseteq D$$

is a kernel function.

Kernels on collections of sets can be defined in terms of measures.

Example 53.7. Let (D, \mathcal{A}) be a measurable space, where D is a nonempty set and \mathcal{A} is a σ -algebra on D (the measurable sets). Let X be a subset of \mathcal{A} . If μ is a positive measure on (D, \mathcal{A}) and if μ is finite, which means that $\mu(D)$ is finite, then we can define the map $\kappa_1: X \times X \rightarrow \mathbb{R}$ given by

$$\kappa_1(A_1, A_2) = \mu(A_1 \cap A_2), \quad A_1, A_2 \in X.$$

We can show that κ is a kernel function as follows. Let $H = L^2_\mu(D, \mathcal{A}, \mathbb{R})$ be the Hilbert space of μ -square-integrable functions with the inner product

$$\langle f, g \rangle = \int_D f(s)g(s) d\mu(s),$$

and let $\varphi: X \rightarrow H$ be the feature embedding given by

$$\varphi(A) = \chi_A, \quad A \in X,$$

the characteristic function of A . Then we have

$$\begin{aligned} \kappa_1(A_1, A_2) &= \mu(A_1 \cap A_2) = \int_D \chi_{A_1 \cap A_2}(s) d\mu(s) \\ &= \int_D \chi_{A_1}(s)\chi_{A_2}(s) d\mu(s) = \langle \chi_{A_1}, \chi_{A_2} \rangle \\ &= \langle \varphi(A_1), \varphi(A_2) \rangle. \end{aligned}$$

The above kernel is called the *intersection kernel*. If we assume that μ is normalized so that $\mu(D) = 1$, then we also have the *union complement kernel*:

$$\kappa_2(A_1, A_2) = \mu(\overline{A_1} \cap \overline{A_2}) = 1 - \mu(A_1 \cup A_2).$$

The sum κ_3 of the kernels κ_1 and κ_2 is the *agreement kernel*:

$$\kappa_s(A_1, A_2) = 1 - \mu(A_1 - A_2) - \mu(A_2 - A_1).$$

Many other kinds of kernels can be designed, in particular, graph kernels. For comprehensive presentations of kernels, see Schölkopf and Smola [145] and Shawe-Taylor and Christianini [159].

Kernel functions have the following important property.

Proposition 53.1. *Let X be any nonempty set, let H be any (complex) Hilbert space, let $\varphi: X \rightarrow H$ be any function, and let $\kappa: X \times X \rightarrow \mathbb{C}$ be the kernel given by*

$$\kappa(x, y) = \langle \varphi(x), \varphi(y) \rangle, \quad x, y \in X.$$

For any finite subset $S = \{x_1, \dots, x_p\}$ of X , if K_S is the $p \times p$ matrix

$$K_S = (\kappa(x_j, x_i))_{1 \leq i, j \leq p} = (\langle \varphi(x_j), \varphi(x_i) \rangle)_{1 \leq i, j \leq p},$$

then we have

$$u^* K_S u \geq 0, \quad \text{for all } u \in \mathbb{C}^p.$$

Proof. We have

$$\begin{aligned} u^* K_S u &= u^\top K_S^\top \bar{u} = \sum_{i,j=1}^p \kappa(x_i, x_j) u_i \bar{u}_j \\ &= \sum_{i,j=1}^p \langle \varphi(x_i), \varphi(x_j) \rangle u_i \bar{u}_j \\ &= \left\langle \sum_{i=1}^p u_i \varphi(x_i), \sum_{j=1}^p u_j \varphi(x_j) \right\rangle = \left\| \sum_{i=1}^p u_i \varphi(x_i) \right\|^2 \geq 0, \end{aligned}$$

as claimed. \square

53.2 Basic Properties of Positive Definite Kernels

Proposition 53.1 suggests a second approach to kernel functions which does not assume that a feature space and a feature map are provided. We will see in Section 53.3 that the two approaches are equivalent. The second approach is useful in practice because it is often difficult to define a feature space and a feature map in a simple manner.

Definition 53.2. Let X be a nonempty set. A function $\kappa: X \times X \rightarrow \mathbb{C}$ is a *positive definite kernel* if for every finite subset $S = \{x_1, \dots, x_p\}$ of X , if K_S is the $p \times p$ matrix

$$K_S = (\kappa(x_j, x_i))_{1 \leq i, j \leq p}$$

called a *Gram matrix*, then we have

$$u^* K_S u = \sum_{i,j=1}^p \kappa(x_i, x_j) u_i \overline{u_j} \geq 0, \quad \text{for all } u \in \mathbb{C}^p.$$

Observe that Definition 53.2 does not require that $u^* K_S u > 0$ if $u \neq 0$, so the terminology *positive definite* is a bit abusive, and it would be more appropriate to use the terminology *positive semidefinite*. However, it seems customary to use the term *positive definite kernel*, or even *positive kernel*.

Proposition 53.2. Let $\kappa: X \times X \rightarrow \mathbb{C}$ be a positive definite kernel. Then $\kappa(x, x) \geq 0$ for all $x \in X$, and for any finite subset $S = \{x_1, \dots, x_p\}$ of X , the $p \times p$ matrix K_S given by

$$K_S = (\kappa(x_j, x_i))_{1 \leq i, j \leq p}$$

is Hermitian, that is, $K_S^* = K_S$.

Proof. The first property is obvious by choosing $S = \{x\}$. To prove that K_S is Hermitian, observe that we have

$$(u + v)^* K_S (u + v) = u^* K_S u + u^* K_S v + v^* K_S u + v^* K_S v,$$

and since $(u + v)^* K_S (u + v), u^* K_S u, v^* K_S v \geq 0$, we deduce that

$$2A = u^* K_S v + v^* K_S u \tag{1}$$

must be real. By replacing u by iu , we see that

$$2B = -iu^* K_S v + iv^* K_S u \tag{2}$$

must also be real. By multiplying Equation (2) by i and adding it to Equation (1) we get

$$u^* K_S v = A + iB. \tag{3}$$

By subtracting Equation (3) from Equation (1) we get

$$v^* K_S u = A - iB.$$

Then

$$u^* K_S^* v = \overline{v^* K_S u} = \overline{A - iB} = A + iB = u^* K_S v,$$

for all $u, v \in \mathbb{C}^*$, which implies $K_S^* = K_S$. \square

If the map $\kappa: X \times X \rightarrow \mathbb{R}$ is real-valued, then we have the following criterion for κ to be a positive definite kernel that only involves real vectors.

Proposition 53.3. *If $\kappa: X \times X \rightarrow \mathbb{R}$, then κ is a positive definite kernel iff for any finite subset $S = \{x_1, \dots, x_p\}$ of X , the $p \times p$ real matrix K_S given by*

$$K_S = (\kappa(x_k, x_j))_{1 \leq j, k \leq p}$$

is symmetric, that is, $K_S^\top = K_S$, and

$$u^\top K_S u = \sum_{j, k=1}^p \kappa(x_j, x_k) u_j u_k \geq 0, \quad \text{for all } u \in \mathbb{R}^p.$$

Proof. If κ is a real-valued positive definite kernel, then the proposition is a trivial consequence of Proposition 53.2.

For the converse assume that κ is symmetric and that it satisfies the second condition of the proposition. We need to show that κ is a positive definite kernel with respect to complex vectors. If we write $u_k = a_k + ib_k$, then

$$\begin{aligned} u^* K_S u &= \sum_{j, k=1}^p \kappa(x_j, x_k) (a_j + ib_j)(a_k - ib_k) \\ &= \sum_{j, k=1}^p (a_j a_k + b_j b_k) \kappa(x_j, x_k) + i \sum_{j, k=1}^p (b_j a_k - a_j b_k) \kappa(x_j, x_k) \\ &= \sum_{j, k=1}^p (a_j a_k + b_j b_k) \kappa(x_j, x_k) + i \sum_{1 \leq j < k \leq p} b_j a_k (\kappa(x_j, x_k) - \kappa(x_k, x_j)). \end{aligned}$$

Thus $u^* K_S u$ is real iff K_S is symmetric. \square

Consequently we make the following definition.

Definition 53.3. Let X be a nonempty set. A function $\kappa: X \times X \rightarrow \mathbb{R}$ is a (*real*) *positive definite kernel* if $\kappa(x, y) = \kappa(y, x)$ for all $x, y \in X$, and for every finite subset $S = \{x_1, \dots, x_p\}$ of X , if K_S is the $p \times p$ real symmetric matrix

$$K_S = (\kappa(x_i, x_j))_{1 \leq i, j \leq p},$$

then we have

$$u^\top K_S u = \sum_{i,j=1}^p \kappa(x_i, x_j) u_i u_j \geq 0, \quad \text{for all } u \in \mathbb{R}^p.$$

Among other things, the next proposition shows that a positive definite kernel satisfies the Cauchy–Schwarz inequality.

Proposition 53.4. *A Hermitian 2×2 matrix*

$$A = \begin{pmatrix} a & \bar{b} \\ b & d \end{pmatrix}$$

is positive semidefinite if and only if $a \geq 0$, $d \geq 0$, and $ad - |b|^2 \geq 0$.

Let $\kappa: X \times X \rightarrow \mathbb{C}$ be a positive definite kernel. For all $x, y \in X$, we have

$$|\kappa(x, y)|^2 \leq \kappa(x, x)\kappa(y, y).$$

Proof. For all $x, y \in \mathbb{C}$, we have

$$\begin{aligned} (\bar{x} & \bar{y}) \begin{pmatrix} a & \bar{b} \\ b & d \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = (\bar{x} & \bar{y}) \begin{pmatrix} ax + \bar{b}y \\ bx + dy \end{pmatrix} \\ &= a|x|^2 + bx\bar{y} + \bar{b}x\bar{y} + d|y|^2. \end{aligned}$$

If A is positive semidefinite, then we already know that $a \geq 0$ and $d \geq 0$. If $a = 0$, then we must have $b = 0$, since otherwise we can make $bx\bar{y} + \bar{b}x\bar{y}$, which is twice the real part of $bx\bar{y}$, as negative as we want. In this case, $ad - |b|^2 = 0$.

If $a > 0$, then

$$a|x|^2 + bx\bar{y} + \bar{b}x\bar{y} + d|y|^2 = a \left| x + \frac{\bar{b}}{a}y \right|^2 + \frac{|y|^2}{a}(ad - |b|^2).$$

If $ad - |b|^2 < 0$, we can pick $y \neq 0$ and $x = -(\bar{b}y)/a$, so that the above expression is negative. Therefore, $ad - |b|^2 \geq 0$. The converse is trivial.

If $x = y$, the inequality $|\kappa(x, y)|^2 \leq \kappa(x, x)\kappa(y, y)$ is trivial. If $x \neq y$, the inequality follows by applying the criterion for being positive semidefinite to the matrix

$$\begin{pmatrix} \kappa(x, x) & \overline{\kappa(x, y)} \\ \kappa(x, y) & \kappa(y, y) \end{pmatrix},$$

as claimed. \square

The following property due to I. Schur (1911) shows that the pointwise product of two positive definite kernels is also a positive definite kernel.

Proposition 53.5. (*I. Schur*) If $\kappa_1: X \times X \rightarrow \mathbb{C}$ and $\kappa_2: X \times X \rightarrow \mathbb{C}$ are two positive definite kernels, then the function $\kappa: X \times X \rightarrow \mathbb{C}$ given by $\kappa(x, y) = \kappa_1(x, y)\kappa_2(x, y)$ for all $x, y \in X$ is also a positive definite kernel.

Proof. It suffices to prove that if $A = (a_{jk})$ and $B = (b_{jk})$ are two Hermitian positive semidefinite $p \times p$ matrices, then so is their pointwise product $C = A \circ B = (a_{jk}b_{jk})$ (also known as Hadamard or Schur product). Recall that a Hermitian positive semidefinite matrix A can be diagonalized as $A = U\Lambda U^*$, where Λ is a diagonal matrix with nonnegative entries and U is a unitary matrix. Let $\Lambda^{1/2}$ be the diagonal matrix consisting of the positive square roots of the diagonal entries in Λ . Then we have

$$A = U\Lambda U^* = U\Lambda^{1/2}\Lambda^{1/2}U^* = U\Lambda^{1/2}(U\Lambda^{1/2})^*.$$

Thus if we set $R = U\Lambda^{1/2}$, we have

$$A = RR^*,$$

which means that

$$a_{jk} = \sum_{h=1}^p r_{jh}\overline{r_{kh}}.$$

Then for any $u \in \mathbb{C}^p$, we have

$$\begin{aligned} u^*(A \circ B)u &= \sum_{j,k=1}^p a_{jk}b_{jk}u_j\overline{u_k} \\ &= \sum_{j,k=1}^p \sum_{h=1}^p r_{jh}\overline{r_{kh}}b_{jk}u_j\overline{u_k} \\ &= \sum_{h=1}^p \sum_{j,k=1}^p b_{jk}u_jr_{jh}\overline{u_kr_{kh}}. \end{aligned}$$

Since B is positive semidefinite, for each fixed h , we have

$$\sum_{j,k=1}^p b_{jk}u_jr_{jh}\overline{u_kr_{kh}} = \sum_{j,k=1}^p b_{jk}z_j\overline{z_k} \geq 0,$$

as we see by letting $z = (u_1r_{1h}, \dots, u_pr_{ph})$, □

In contrast, the ordinary product AB of two symmetric positive semidefinite matrices A and B may not be symmetric positive semidefinite; see Section 8.9 for an example.

Here are other ways of obtaining new positive definite kernels from old ones.

Proposition 53.6. Let $\kappa_1: X \times X \rightarrow \mathbb{C}$ and $\kappa_2: X \times X \rightarrow \mathbb{C}$ be two positive definite kernels, $f: X \rightarrow \mathbb{C}$ be a function, $\psi: X \rightarrow \mathbb{R}^N$ be a function, $\kappa_3: \mathbb{R}^N \times \mathbb{R}^N \rightarrow \mathbb{C}$ be a positive definite kernel, and $a \in \mathbb{R}$ be any positive real number. Then the following functions are positive definite kernels:

$$(1) \quad \kappa(x, y) = \kappa_1(x, y) + \kappa_2(x, y).$$

$$(2) \quad \kappa(x, y) = a\kappa_1(x, y).$$

$$(3) \quad \kappa(x, y) = f(x)\overline{f(y)}.$$

$$(4) \quad \kappa(x, y) = \kappa_3(\psi(x), \psi(y)).$$

(5) If B is a symmetric positive semidefinite $n \times n$ matrix, then the map
 $\kappa: \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}$ given by

$$\kappa(x, y) = x^\top B y$$

is a positive definite kernel.

Proof. (1) For every finite subset $S = \{x_1, \dots, x_p\}$ of X , if K_1 is the $p \times p$ matrix

$$K_1 = (\kappa_1(x_k, x_j))_{1 \leq j, k \leq p}$$

and if K_2 is the $p \times p$ matrix

$$K_2 = (\kappa_2(x_k, x_j))_{1 \leq j, k \leq p},$$

then for any $u \in \mathbb{C}^p$, we have

$$u^*(K_1 + K_2)u = u^*K_1u + u^*K_2u \geq 0,$$

since $u^*K_1u \geq 0$ and $u^*K_2u \geq 0$ because κ_1 and κ_2 are positive definite kernels, which means that K_1 and K_2 are positive semidefinite.

(2) We have

$$u^*(aK_1)u = au^*K_1u \geq 0,$$

since $a > 0$ and $u^*K_1u \geq 0$.

(3) For every finite subset $S = \{x_1, \dots, x_p\}$ of X , if K is the $p \times p$ matrix

$$K = (\kappa(x_k, x_j))_{1 \leq j, k \leq p} = (\overline{f(x_k)}f(x_j))_{1 \leq j, k \leq p}$$

then we have

$$u^*Ku = u^\top K^\top \bar{u} = \sum_{j, k=1}^p \kappa(x_j, x_k) u_j \bar{u}_k = \sum_{j, k=1}^p u_j f(x_j) \overline{u_k f(x_k)} = \left| \sum_{j=1}^p u_j f(x_j) \right|^2 \geq 0.$$

(4) For every finite subset $S = \{x_1, \dots, x_p\}$ of X , the $p \times p$ matrix K given by

$$K = (\kappa(x_k, x_j))_{1 \leq j, k \leq p} = (\kappa_3(\psi(x_k), \psi(x_j)))_{1 \leq j, k \leq p}$$

is symmetric positive semidefinite since κ_3 is a positive definite kernel.

(5) As in the proof of Proposition 53.5 (adapted to the real case) there is a matrix R such that

$$B = RR^\top,$$

so

$$\kappa(x, y) = x^\top By = x^\top RR^\top y = (R^\top x)^\top R^\top y = \langle R^\top x, R^\top y \rangle,$$

so κ is the kernel function given by the feature map $\varphi(x) = R^\top x$ from \mathbb{R}^n to itself, and by Proposition 53.1, it is a symmetric positive definite kernel. \square

Proposition 53.7. *Let $\kappa_1: X \times X \rightarrow \mathbb{C}$ be a positive definite kernel, and let $p(z)$ be a polynomial with nonnegative coefficients. Then the following functions κ defined below are also positive definite kernels.*

$$(1) \quad \kappa(x, y) = p(\kappa_1(x, y)).$$

$$(2) \quad \kappa(x, y) = e^{\kappa_1(x, y)}.$$

(3) If X is real Hilbert space with inner product $\langle \cdot, \cdot \rangle_X$ and corresponding norm $\| \cdot \|_X$,

$$\kappa(x, y) = e^{-\frac{\|x-y\|_X^2}{2\sigma^2}}$$

for any $\sigma > 0$.

Proof. (1) If $p(z) = a_m z^m + \cdots + a_1 z + a_0$, then

$$p(\kappa_1(x, y)) = a_m \kappa_1(x, y)^m + \cdots + a_1 \kappa_1(x, y) + a_0.$$

Since $a_k \geq 0$ for $k = 0, \dots, m$, by Proposition 53.5 and Proposition 53.6(2), each function $a_k \kappa_i(x, y)^k$ with $1 \leq k \leq m$ is a positive definite kernel, by Proposition 53.6(3) with $f(x) = \sqrt{a_0}$, the constant function a_0 is a positive definite kernel, and by Proposition 53.6(1), $p(\kappa_1(x, y))$ is a positive definite kernel.

(2) We have

$$e^{\kappa_1(x, y)} = \sum_{k=0}^{\infty} \frac{\kappa_1(x, y)^k}{k!}.$$

By (1), the partial sums

$$\sum_{k=0}^m \frac{\kappa_1(x, y)^k}{k!}$$

are positive definite kernels, and since $e^{\kappa_1(x, y)}$ is the (uniform) pointwise limit of positive definite kernels, it is also a positive definite kernel.

(3) By Proposition 53.6(2), since the map $(x, y) \mapsto \langle x, y \rangle_X$ is obviously a positive definite kernel (the feature map is the identity) and since $\sigma \neq 0$, the function $(x, y) \mapsto \langle x, y \rangle_X / \sigma^2$ is a positive definite kernel (by Proposition 53.6(2)), so by (2),

$$\kappa_1(x, y) = e^{\frac{\langle x, y \rangle_X}{\sigma^2}}$$

is a positive definite kernel. Let $f: X \rightarrow \mathbb{R}$ be the function given by

$$f(x) = e^{-\frac{\|x\|^2}{2\sigma^2}}.$$

Then by Proposition 53.6(3),

$$\kappa_2(x, y) = f(x)f(y) = e^{-\frac{\|x\|^2}{2\sigma^2}}e^{-\frac{\|y\|^2}{2\sigma^2}} = e^{-\frac{\|x\|_X^2 + \|y\|_X^2}{2\sigma^2}}$$

is a positive definite kernel. By Proposition 53.5, the function $\kappa_1\kappa_2$ is a positive definite kernel, that is

$$\kappa_1(x, y)\kappa_2(x, y) = e^{\frac{\langle x, y \rangle_X}{\sigma^2}}e^{-\frac{\|x\|_X^2 + \|y\|_X^2}{2\sigma^2}} = e^{\frac{\langle x, y \rangle_X}{\sigma^2} - \frac{\|x\|_X^2 + \|y\|_X^2}{2\sigma^2}} = e^{-\frac{\|x-y\|_X^2}{2\sigma^2}}$$

is a positive definite kernel. \square

Definition 53.4. The positive definite kernel

$$\kappa(x, y) = e^{-\frac{\|x-y\|_X^2}{2\sigma^2}}$$

is called a *Gaussian kernel*.

This kernel requires a feature map in an infinite-dimensional space because it is an infinite sum of distinct kernels.

Remark: If κ_1 is a positive definite kernel, the proof of Proposition 53.7(3) is immediately adapted to show that

$$\kappa(x, y) = e^{-\frac{\kappa_1(x, x) + \kappa_1(y, y) - 2\kappa_1(x, y)}{2\sigma^2}}$$

is a positive definite kernel.

Next we prove that every positive definite kernel arises from a feature map in a Hilbert space which is a function space.

53.3 Hilbert Space Representation of a Positive Definite Kernel

The following result shows how to construct a so-called *reproducing kernel Hilbert space*, for short RKHS, from a positive definite kernel.

Theorem 53.8. *Let $\kappa: X \times X \rightarrow \mathbb{C}$ be a positive definite kernel on a nonempty set X . For every $x \in X$, let $\kappa_x: X \rightarrow \mathbb{C}$ be the function given by*

$$\kappa_x(y) = \kappa(x, y), \quad y \in X.$$

Let H_0 be the subspace of the vector space \mathbb{C}^X of functions from X to \mathbb{C} spanned by the family of functions $(\kappa_x)_{x \in X}$, and let $\varphi: X \rightarrow H_0$ be the map given by $\varphi(x) = \kappa_x$. There is a Hermitian inner product $\langle -, - \rangle$ on H_0 such that

$$\kappa(x, y) = \langle \varphi(x), \varphi(y) \rangle, \quad \text{for all } x, y \in X.$$

The completion H of H_0 is a Hilbert space, and the map $\eta: H \rightarrow \mathbb{C}^X$ given by

$$\eta(f)(x) = \langle f, \kappa_x \rangle, \quad x \in X,$$

is linear and injective, so H can be identified with a subspace of \mathbb{C}^X . We also have

$$\kappa(x, y) = \langle \varphi(x), \varphi(y) \rangle, \quad \text{for all } x, y \in X.$$

For all $f \in H_0$ and all $x \in X$,

$$\langle f, \kappa_x \rangle = f(x), \tag{*}$$

a property known as the **reproducing property**.

Proof.

Step 1. Define a candidate inner product.

For any two linear combinations $f = \sum_{j=1}^p \alpha_j \kappa_{x_j}$ and $g = \sum_{k=1}^q \beta_k \kappa_{y_k}$ in H_0 , with $x_j, y_k \in X$ and $\alpha_j, \beta_k \in \mathbb{C}$, define $\langle f, g \rangle$ by

$$\langle f, g \rangle = \sum_{j=1}^p \sum_{k=1}^q \alpha_j \overline{\beta_k} \kappa(x_j, y_k). \tag{\dagger}$$

At first glance, the above expression appears to depend on the expression of f and g as linear combinations, but since $\kappa(x_j, y_k) = \kappa(y_k, x_j)$, observe that

$$\sum_{k=1}^q \overline{\beta_k} f(y_k) = \sum_{j=1}^p \sum_{k=1}^q \alpha_j \overline{\beta_k} \kappa(x_j, y_k) = \sum_{j=1}^p \alpha_j \overline{g(x_j)}, \tag{*}$$

and since the first and the third term are equal for all linear combinations representing f and g , we conclude that (\dagger) depends only on f and g and not on their representation as a linear combination.

Step 2. Prove that the inner product defined by (\dagger) is Hermitian semidefinite.

Obviously (\dagger) defines a Hermitian sequilinear form. For every $f \in H_0$, we have

$$\langle f, f \rangle = \sum_{j,k=1}^p \alpha_j \overline{\alpha_k} \kappa(x_j, x_k) \geq 0,$$

since κ is a positive definite kernel.

Step 3. Prove that the inner product defined by (\dagger) is positive definite.

For any finite subset $\{f_1, \dots, f_n\}$ of H_0 and any $z \in \mathbb{C}^n$, we have

$$\sum_{j,k=1}^n \langle f_j, f_k \rangle z_j \overline{z_k} = \left\langle \sum_{j=1}^n z_j f_j, \sum_{j=1}^n z_j f_j \right\rangle \geq 0,$$

which shows that the map $(f, g) \mapsto \langle f, g \rangle$ from $H_0 \times H_0$ to \mathbb{C} is a positive definite kernel.

Observe that for all $f \in H_0$ and all $x \in X$, (\dagger) implies that

$$\langle f, \kappa_x \rangle = \sum_{j=1}^k \alpha_j \kappa(x_j, x) = f(x),$$

a property known as the *reproducing property*. The above implies that

$$\langle \kappa_x, \kappa_y \rangle = \kappa(x, y). \quad (**)$$

By Proposition 53.4 applied to the positive definite kernel $(f, g) \mapsto \langle f, g \rangle$, we have

$$|\langle f, \kappa_x \rangle|^2 \leq \langle f, f \rangle \langle \kappa_x, \kappa_x \rangle,$$

that is,

$$|f(x)|^2 \leq \langle f, f \rangle \kappa(x, x),$$

so $\langle f, f \rangle = 0$ implies that $f(x) = 0$ for all $x \in X$, which means that $\langle -, - \rangle$ as defined by (\dagger) is positive definite. Therefore, $\langle -, - \rangle$ is a Hermitian inner product on H_0 , and by $(**)$ and since $\varphi(x) = \kappa_x$, we have

$$\kappa(x, y) = \langle \varphi(x), \varphi(y) \rangle, \quad \text{for all } x, y \in X.$$

Step 4. Define the embedding η .

Let H be the Hilbert space which is the completion of H_0 , so that H_0 is dense in H . The map $\eta: H \rightarrow \mathbb{C}^X$ given by

$$\eta(f)(x) = \langle f, \kappa_x \rangle$$

is obviously linear, and it is injective because the family $(\kappa_x)_{x \in X}$ spans H_0 which is dense in H , thus it is also dense in H , so if $\langle f, \kappa_x \rangle = 0$ for all $x \in X$, then $f = 0$. \square

Corollary 53.9. *If we identify a function $f \in H$ with the function $\eta(f)$, then we have the reproducing property*

$$\langle f, \kappa_x \rangle = f(x), \quad \text{for all } f \in H \text{ and all } x \in X.$$

If X is finite, then \mathbb{C}^X is finite-dimensional. If X is a separable topological space and if κ is continuous, then it can be shown that H is a separable Hilbert space.

Also, if $\kappa: X \times X \rightarrow \mathbb{R}$ is a real symmetric positive definite kernel, then we see immediately that Theorem 53.8 holds with H_0 a real Euclidean space and H a real Hilbert space.

*** Remark:** If $X = G$, where G is a locally compact group, then a function $p: G \rightarrow \mathbb{C}$ (not necessarily continuous) is *positive semidefinite* if for all $s_1, \dots, s_n \in G$ and all $\xi_1, \dots, \xi_n \in \mathbb{C}$, we have

$$\sum_{j,k=1}^n p(s_j^{-1}s_k)\xi_k\overline{\xi_j} \geq 0.$$

So if we define $\kappa: G \times G \rightarrow \mathbb{C}$ by

$$\kappa(s, t) = p(t^{-1}s),$$

then κ is a positive definite kernel on G . If p is continuous, then it is known that p arises from a unitary representation $U: G \rightarrow \mathbf{U}(H)$ of the group G in a Hilbert space H with inner product $\langle -, - \rangle$ (a homomorphism with a certain continuity property), in the sense that there is some vector $x_0 \in H$ such that

$$p(s) = \langle U(s)(x_0), x_0 \rangle, \quad \text{for all } s \in G.$$

Since the $U(s)$ are unitary operators on H ,

$$\begin{aligned} p(t^{-1}s) &= \langle U(t^{-1}s)(x_0), x_0 \rangle = \langle U(t^{-1})(U(s)(x_0)), x_0 \rangle \\ &= \langle U(t)^*(U(s)(x_0)), x_0 \rangle = \langle U(s)(x_0), U(t)(x_0) \rangle, \end{aligned}$$

which shows that

$$\kappa(s, t) = \langle U(s)(x_0), U(t)(x_0) \rangle,$$

so the map $\varphi: G \rightarrow H$ given by

$$\varphi(s) = U(s)(x_0)$$

is a feature map into the feature space H . This theorem is due to Gelfand and Raikov (1943).

The proof of Theorem 53.8 is essentially identical to part of Godement's proof of the above result about the correspondence between functions of positive type and unitary representations; see Helgason [90], Chapter IV, Theorem 1.5. Theorem 53.8 is a little more general since it does not assume that X is a group, but when G is a group, the feature map arises from a unitary representation.

53.4 Kernel PCA

As an application of kernel functions, we discuss a generalization of the method of principal component analysis (PCA). Suppose we have a set of data $S = \{x_1, \dots, x_n\}$ in some input space \mathcal{X} , and pretend that we have an embedding $\varphi: \mathcal{X} \rightarrow F$ of \mathcal{X} in a (real) feature space $(F, \langle -, - \rangle)$, but that we only have access to the kernel function $\kappa(x, y) = \langle \varphi(x), \varphi(y) \rangle$. We would like to do PCA analysis on the set $\varphi(S) = \{\varphi(x_1), \dots, \varphi(x_n)\}$.

There are two obstacles:

- (1) We need to center the data and compute the inner products of pairs of centered data. More precisely, if the centroid of $\varphi(S)$ is

$$\mu = \frac{1}{n}(\varphi(x_1) + \cdots + \varphi(x_n)),$$

then we need to compute the inner products $\langle \varphi(x) - \mu, \varphi(y) - \mu \rangle$.

- (2) Let us assume that $F = \mathbb{R}^d$ with the standard Euclidean inner product and that the data points $\varphi(x_i)$ are expressed as *row vectors* X_i of an $n \times d$ matrix X (as it is customary). Then the inner products $\kappa(x_i, x_j) = \langle \varphi(x_i), \varphi(x_j) \rangle$ are given by the *kernel matrix* $\mathbf{K} = XX^\top$. Be aware that with this representation, in the expression $\langle \varphi(x_i), \varphi(x_j) \rangle$, $\varphi(x_i)$ is a d -dimensional column vector, while $\varphi(x_i) = X_i^\top$. However, the j th component $(Y_k)_j$ of the principal component Y_k (viewed as a n -dimensional column vector) is given by the projection of $\widehat{X}_j = X_j - \mu$ onto the direction u_k (viewing μ as a d -dimensional row vector), which is a unit eigenvector of the matrix $(X - \mu)^\top(X - \mu)$ (where $\widehat{X} = X - \mu$ is the matrix whose j th row is $\widehat{X}_j = X_j - \mu$), is given by the inner product

$$\langle X_j - \mu, u_k \rangle = (Y_k)_j;$$

see Definition 23.2 and Theorem 23.11. The problem is that we know what the matrix $(X - \mu)(X - \mu)^\top$ is from (1), because it can be expressed in terms of \mathbf{K} , but we don't know what $(X - \mu)^\top(X - \mu)$ is because we don't have access to $\widehat{X} = X - \mu$.

Both difficulties are easily overcome. For (1) we have

$$\begin{aligned} \langle \varphi(x) - \mu, \varphi(y) - \mu \rangle &= \left\langle \varphi(x) - \frac{1}{n} \sum_{k=1}^n \varphi(x_k), \varphi(y) - \frac{1}{n} \sum_{k=1}^n \varphi(x_k) \right\rangle \\ &= \kappa(x, y) - \frac{1}{n} \sum_{i=1}^n \kappa(x, x_i) - \frac{1}{n} \sum_{j=1}^n \kappa(x_j, y) + \frac{1}{n^2} \sum_{i,j=1}^n \kappa(x_i, x_j). \end{aligned}$$

For (2), if \mathbf{K} is the kernel matrix $\mathbf{K} = (\kappa(x_i, x_j))$, then the kernel matrix $\widehat{\mathbf{K}}$ corresponding to the kernel function $\widehat{\kappa}$ given by

$$\widehat{\kappa}(x, y) = \langle \varphi(x) - \mu, \varphi(y) - \mu \rangle$$

can be expressed in terms of \mathbf{K} . Let $\mathbf{1}$ be the column vector (of dimension n) whose entries are all 1. Then $\mathbf{1}\mathbf{1}^\top$ is the $n \times n$ matrix whose entries are all 1. If A is an $n \times n$ matrix, then $\mathbf{1}^\top A$ is the row vector consisting of the sums of the columns of A , $A\mathbf{1}$ is the column vector consisting of the sums of the rows of A , and $\mathbf{1}^\top A\mathbf{1}$ is the sum of all the entries in A . Then it is easy to see that the kernel matrix corresponding to the kernel function $\widehat{\kappa}$ is given by

$$\widehat{\mathbf{K}} = \mathbf{K} - \frac{1}{n} \mathbf{1}\mathbf{1}^\top \mathbf{K} - \frac{1}{n} \mathbf{K}\mathbf{1}\mathbf{1}^\top + \frac{1}{n^2} (\mathbf{1}^\top \mathbf{K}\mathbf{1}) \mathbf{1}\mathbf{1}^\top.$$

Suppose $\widehat{X} = X - \mu$ has rank r . To overcome the second problem, note that if

$$\widehat{X} = VDU^\top$$

is an SVD for \widehat{X} , then

$$\widehat{X}^\top = U D^\top V^\top$$

is an SVD for \widehat{X}^\top , and the $r \times r$ submatrix of D^\top consisting of the first r rows and r columns of D^\top (and D), is the diagonal Σ_r matrix consisting of the singular values $\sigma_1 \geq \dots \geq \sigma_r$ of \widehat{X} , so we can express the matrix U_r consisting of the first r columns u_k of U in terms of the matrix V_r consisting of the first r columns v_k of V ($1 \leq k \leq r$) as

$$U_r = \widehat{X}^\top V_r \Sigma_r^{-1}.$$

Furthermore, $\sigma_1^2 \geq \dots \geq \sigma_r^2$ are the nonzero eigenvalues of $\widehat{\mathbf{K}} = \widehat{X} \widehat{X}^\top$, and the columns of V_r are corresponding unit eigenvectors of $\widehat{\mathbf{K}}$. From

$$U_r = \widehat{X}^\top V_r \Sigma_r^{-1}$$

the k th column u_k of U_r (which is a unit eigenvector of $\widehat{X}^\top \widehat{X}$ associated with the eigenvalue σ_k^2) is given by

$$u_k = \sum_{i=1}^n \sigma_k^{-1}(v_k)_i \widehat{X}_i^\top = \sum_{i=1}^n \sigma_k^{-1}(v_k)_i \widehat{\varphi}(x_i), \quad 1 \leq k \leq r,$$

so the projection of $\widehat{\varphi}(x)$ onto u_k is given by

$$\begin{aligned} \langle \widehat{\varphi}(x), u_k \rangle &= \left\langle \widehat{\varphi}(x), \sum_{i=1}^n \sigma_k^{-1}(v_k)_i \widehat{\varphi}(x_i) \right\rangle \\ &= \sum_{i=1}^n \sigma_k^{-1}(v_k)_i \langle \widehat{\varphi}(x), \widehat{\varphi}(x_i) \rangle = \sum_{i=1}^n \sigma_k^{-1}(v_k)_i \widehat{\kappa}(x, x_i). \end{aligned}$$

Therefore, the j th component of the principal component Y_k in the principal direction u_k is given by

$$(Y_k)_j = \langle X_j - \mu, u_k \rangle = \sum_{i=1}^n \sigma_k^{-1}(v_k)_i \widehat{\kappa}(x_j, x_i) = \sum_{i=1}^n \sigma_k^{-1}(v_k)_i \widehat{\mathbf{K}}_{ij}.$$

The generalization of kernel PCA to a general embedding $\varphi: \mathcal{X} \rightarrow F$ of \mathcal{X} in a (real) feature space $(F, \langle -, - \rangle)$ (where F is not restricted to be equal to \mathbb{R}^d) with the kernel matrix \mathbf{K} given by

$$\mathbf{K}_{ij} = \langle \varphi(x_i), \varphi(x_j) \rangle,$$

goes as follows.

- Let r be the rank of $\widehat{\mathbf{K}}$, where

$$\widehat{\mathbf{K}} = \mathbf{K} - \frac{1}{n} \mathbf{1} \mathbf{1}^\top \mathbf{K} - \frac{1}{n} \mathbf{K} \mathbf{1} \mathbf{1}^\top + \frac{1}{n^2} (\mathbf{1}^\top \mathbf{K} \mathbf{1}) \mathbf{1} \mathbf{1}^\top,$$

let $\sigma_1^2 \geq \dots \geq \sigma_r^2$ be the nonzero eigenvalues of $\widehat{\mathbf{K}}$, and let v_1, \dots, v_r be corresponding unit eigenvectors. The notation

$$\alpha_k = \sigma_k^{-1} v_k$$

is often used, where the α_k are called the *dual variables*.

- The column vector Y_k ($1 \leq k \leq r$) defined by

$$Y_k = \left(\sum_{i=1}^n (\alpha_k)_i \widehat{\mathbf{K}}_{ij} \right)_{j=1}^n$$

is called the *kth kernel principal component* (for short *kth kernel PCA*) of the data set $S = \{x_1, \dots, x_n\}$ in the direction $u_k = \sum_{i=1}^n \sigma_k^{-1} (v_k)_i \widehat{X}_i^\top$ (even though the matrix \widehat{X} is *not known*).

53.5 Summary

The main concepts and results of this chapter are listed below:

- Feature map, feature embedding, feature space.
- Kernel function.
- Positive definite kernel, real positive definite kernel.
- Gram matrix.
- Hadamard product, Schur product.
- Gaussian kernel.
- Reproducing kernel Hilbert space (RKHS).
- Reproducing property.
- Intersection kernel, union complement kernel, agreement kernel.
- Kernel PCA.
- k -th kernel PCA.

53.6 Problems

Problem 53.1. Referring back to Example 53.3, prove that if $\varphi_1: X \rightarrow \mathbb{R}^{n_1}$ and $\varphi_2: X \rightarrow \mathbb{R}^{n_2}$ are two feature maps and if $\kappa_1(x, y) = \langle \varphi_1(x), \varphi_1(y) \rangle$ and $\kappa_2(x, y) = \langle \varphi_2(x), \varphi_2(y) \rangle$ are the corresponding kernel functions, then the map defined by

$$\kappa(x, y) = \kappa_1(x, y)\kappa_2(x, y)$$

is a kernel function, for the feature space $\mathbb{R}^{n_1} \times \mathbb{R}^{n_2}$ and the feature map

$$\varphi(x)_{(i,j)} = (\varphi_1(x))_i(\varphi_2(x))_j, \quad 1 \leq i \leq n_1, 1 \leq j \leq n_2.$$

Problem 53.2. Referring back to Example 53.3, prove that the feature embedding $\varphi: X \rightarrow \mathbb{R}^{\binom{n+m-1}{m}}$ given by

$$\varphi_{(i_1, \dots, i_n)}(x) = \binom{m}{i_1 \dots i_n}^{1/2} (\varphi_1(x))_1^{i_1} (\varphi_1(x))_2^{i_2} \cdots (\varphi_1(x))_m^{i_m}, \quad i_1 + i_2 + \cdots + i_n = m, i_j \in \mathbb{N},$$

where the n -tuples (i_1, \dots, i_n) are ordered lexicographically, defines the kernel function κ given by $\kappa(x, y) = (\kappa_1(x, y))^m$.

Problem 53.3. In Example 53.6, prove that for any two subsets A_1 and A_2 of D ,

$$\langle \varphi(A_1), \varphi(A_2) \rangle = 2^{|A_1 \cap A_2|},$$

the number of common subsets of A_1 and A_2 .

Problem 53.4. Prove that the pointwise limit of positive definite kernels is also a positive definite kernel.

Problem 53.5. Prove that if κ_1 is a positive definite kernel, then

$$\kappa(x, y) = e^{-\frac{\kappa_1(x, x) + \kappa_1(y, y) - 2\kappa_1(x, y)}{2\sigma^2}}$$

is a positive definite kernel.

Chapter 54

Soft Margin Support Vector Machines

In Sections 50.5 and 50.6 we considered the problem of separating two nonempty disjoint finite sets of p blue points $\{u_i\}_{i=1}^p$ and q red points $\{v_j\}_{j=1}^q$ in \mathbb{R}^n . The goal is to find a hyperplane H of equation $w^\top x - b = 0$ (where $w \in \mathbb{R}^n$ is a nonzero vector and $b \in \mathbb{R}$), such that all the blue points u_i are in one of the two open half-spaces determined by H , and all the red points v_j are in the other open half-space determined by H ; see Figure 54.1.

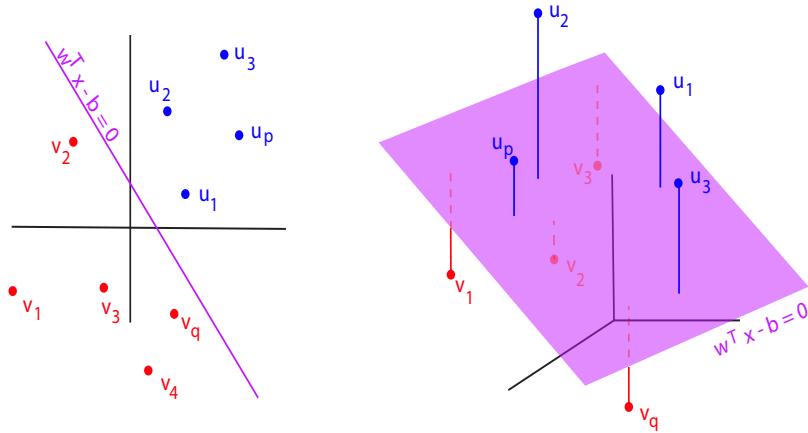

Figure 54.1: Two examples of the SVM separation problem. The left figure is SVM in \mathbb{R}^2 , while the right figure is SVM in \mathbb{R}^3 .

SVM picks a hyperplane which maximizes the minimum distance from these points to the hyperplane.

In this chapter we return to the problem of separating two disjoint sets of points, $\{u_i\}_{i=1}^p$ and $\{v_j\}_{j=1}^q$, but this time we do not assume that these two sets are separable. To cope with nonseparability, we allow points to invade the safety zone around the separating hyperplane, and even points on the wrong side of the hyperplane. Such a method is called *soft margin support vector machine*. We discuss variations of this method, including ν -SV classification. In each case we present a careful derivation of the dual.

If the sets of points $\{u_1, \dots, u_p\}$ and $\{v_1, \dots, v_q\}$ are not linearly separable (with $u_i, v_j \in \mathbb{R}^n$), we can use a trick from linear programming which is to introduce nonnegative “slack variables” $\epsilon = (\epsilon_1, \dots, \epsilon_p) \in \mathbb{R}^p$ and $\xi = (\xi_1, \dots, \xi_q) \in \mathbb{R}^q$ to relax the “hard” constraints

$$\begin{aligned} w^\top u_i - b &\geq \delta & i = 1, \dots, p \\ -w^\top v_j + b &\geq \delta & j = 1, \dots, q \end{aligned}$$

of Problem (SVM_{h1}) from Section 50.5 to the “soft” constraints

$$\begin{aligned} w^\top u_i - b &\geq \delta - \epsilon_i, & \epsilon_i \geq 0 & i = 1, \dots, p \\ -w^\top v_j + b &\geq \delta - \xi_j, & \xi_j \geq 0 & j = 1, \dots, q. \end{aligned}$$

Recall that $w \in \mathbb{R}^n$ and $b, \delta \in \mathbb{R}$.

If $\epsilon_i > 0$, the point u_i may be misclassified, in the sense that it can belong to the margin (the slab), or even to the wrong half-space classifying the negative (red) points. See Figures 54.5 (2) and (3). Similarly, if $\xi_j > 0$, the point v_j may be misclassified, in the sense that it can belong to the margin (the slab), or even to the wrong half-space classifying the positive (blue) points. We can think of ϵ_i as a measure of how much the constraint $w^\top u_i - b \geq \delta$ is violated, and similarly of ξ_j as a measure of how much the constraint $-w^\top v_j + b \geq \delta$ is violated. If $\epsilon = 0$ and $\xi = 0$, then we recover the original constraints. By making ϵ and ξ large enough, these constraints can always be satisfied. We add the constraint $w^\top w \leq 1$ and we minimize $-\delta$.

If instead of the constraints of Problem (SVM_{h1}) we use the hard constraints

$$\begin{aligned} w^\top u_i - b &\geq 1 & i = 1, \dots, p \\ -w^\top v_j + b &\geq 1 & j = 1, \dots, q \end{aligned}$$

of Problem (SVM_{h2}) (see Example 50.6), then we relax to the soft constraints

$$\begin{aligned} w^\top u_i - b &\geq 1 - \epsilon_i, & \epsilon_i \geq 0 & i = 1, \dots, p \\ -w^\top v_j + b &\geq 1 - \xi_j, & \xi_j \geq 0 & j = 1, \dots, q. \end{aligned}$$

In this case there is no constraint on w , but we minimize $(1/2)w^\top w$.

Ideally we would like to find a separating hyperplane that *minimizes the number of misclassified points*, which means that the variables ϵ_i and ξ_j should be as small as possible, but there is a trade-off in maximizing the margin (the thickness of the slab), and minimizing the number of misclassified points. This is reflected in the choice of the objective function, and there are several options, depending on whether we minimize a linear function of the variables ϵ_i and ξ_j , or a quadratic functions of these variables, or whether we include the term $(1/2)b^2$ in the objective function. These methods are known as *support vector classification* algorithms (for short *SVC* algorithms).

SVC algorithms seek an “optimal” separating hyperplane H of equation $w^\top x - b = 0$. If some new data $x \in \mathbb{R}^n$ comes in, we can classify it by determining in which of the two half spaces determined by the hyperplane H they belong by computing the sign of the quantity $w^\top x - b$. The function $\text{sgn}: \mathbb{R} \rightarrow \{-1, 1\}$ is given by

$$\text{sgn}(x) = \begin{cases} +1 & \text{if } x \geq 0 \\ -1 & \text{if } x < 0. \end{cases}$$

Then we define the (*binary*) *classification function* associated with the hyperplane H of equation $w^\top x - b = 0$ as

$$f(x) = \text{sgn}(w^\top x - b).$$

Remarkably, all the known optimization problems for finding this hyperplane share the property that the weight vector w and the constant b are given by expressions that *only involves inner products of the input data points u_i and v_j* , and so does the classification function

$$f(x) = \text{sgn}(w^\top x - b).$$

This is a key fact that allows a far reaching generalization of the support vector machine using the method of *kernels*.

The method of kernels consists in assuming that the input space \mathbb{R}^n is embedded in a larger (possibly infinite dimensional) Euclidean space F (with an inner product $\langle -, - \rangle$) usually called a *feature space*, using a function

$$\varphi: \mathbb{R}^n \rightarrow F$$

called a *feature map*. The function $\kappa: \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}$ given by

$$\kappa(x, y) = \langle \varphi(x), \varphi(y) \rangle$$

is the kernel function associated with the embedding φ ; see Chapter 53. **The idea is that the feature map φ “unwinds” the input data, making it somehow more linear in the higher dimensional space F .** Now even if we don’t know what the feature space F is and what the embedding map φ is, we can pretend to solve our separation problem in F for the embedded data points $\varphi(u_i)$ and $\varphi(v_j)$. Thus we seek a hyperplane H of equation

$$\langle w, \zeta \rangle - b = 0, \quad \zeta \in F,$$

in the feature space F , to attempt to separate the points $\varphi(u_i)$ and the points $\varphi(v_j)$. As we said, it turns out that w and b are given by expression involving only the inner products $\kappa(u_i, u_j) = \langle \varphi(u_i), \varphi(u_j) \rangle$, $\kappa(u_i, v_j) = \langle \varphi(u_i), \varphi(v_j) \rangle$, and $\kappa(v_i, v_j) = \langle \varphi(v_i), \varphi(v_j) \rangle$, which form the symmetric $(p+q) \times (p+q)$ matrix \mathbf{K} (a kernel matrix) given by

$$\mathbf{K}_{ij} = \begin{cases} \kappa(u_i, u_j) & 1 \leq i \leq p, 1 \leq j \leq q \\ -\kappa(u_i, v_{j-p}) & 1 \leq i \leq p, p+1 \leq j \leq p+q \\ -\kappa(v_{i-p}, u_j) & p+1 \leq i \leq p+q, 1 \leq j \leq p \\ \kappa(v_{i-p}, v_{j-q}) & p+1 \leq i \leq p+q, p+1 \leq j \leq p+q. \end{cases}$$

For example, if $p = 2$ and $q = 3$, we have the matrix

$$\mathbf{K} = \begin{pmatrix} \kappa(u_1, u_1) & \kappa(u_1, u_2) & -\kappa(u_1, v_1) & -\kappa(u_1, v_2) & -\kappa(u_1, v_3) \\ \kappa(u_2, u_1) & \kappa(u_2, u_2) & -\kappa(u_2, v_1) & -\kappa(u_2, v_2) & -\kappa(u_2, v_3) \\ -\kappa(v_1, u_1) & -\kappa(v_1, u_2) & \kappa(v_1, v_1) & \kappa(v_1, v_2) & \kappa(v_1, v_3) \\ -\kappa(v_2, u_1) & -\kappa(v_2, u_2) & \kappa(v_2, v_1) & \kappa(v_2, v_2) & \kappa(v_2, v_3) \\ -\kappa(v_3, u_1) & -\kappa(v_3, u_2) & \kappa(v_3, v_1) & \kappa(v_3, v_2) & \kappa(v_3, v_3) \end{pmatrix}.$$

Then the classification function

$$f(x) = \text{sgn}(\langle w, \varphi(x) \rangle - b)$$

for points in the original data space \mathbb{R}^n is also expressed solely in terms of the matrix \mathbf{K} and the inner products $\kappa(u_i, x) = \langle \varphi(u_i), \varphi(x) \rangle$ and $\kappa(v_j, x) = \langle \varphi(v_j), \varphi(x) \rangle$. As a consequence, in the original data space \mathbb{R}^n , the hypersurface

$$\mathcal{S} = \{x \in \mathbb{R}^n \mid \langle w, \varphi(x) \rangle - b = 0\}$$

separates the data points u_i and v_j , but it is not an affine subspace of \mathbb{R}^n . The classification function f tells us on which “side” of \mathcal{S} is a new data point $x \in \mathbb{R}^n$. Thus, we managed to separate the data points u_i and v_j that are not separable by an affine hyperplane, by a *nonaffine hypersurface* \mathcal{S} , by assuming that an embedding $\varphi: \mathbb{R}^n \rightarrow F$ exists, even though we don’t know what it is, but having access to F through the kernel function $\kappa: \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}$ given by the inner products $\kappa(x, y) = \langle \varphi(x), \varphi(y) \rangle$.

In practice the art of using the kernel method is to choose the right kernel (as the knight says in Indiana Jones, to “choose wisely.”).

The method of kernels is very flexible. It also applies to the soft margin versions of SVM, but also to regression problems, to principal component analysis (PCA), and to other problems arising in machine learning.

We discussed the method of kernels in Chapter 53. Other comprehensive presentations of the method of kernels are found in Schölkopf and Smola [145] and Shawe-Taylor and Christianini [159]. See also Bishop [23].

We first consider the soft margin SVM arising from Problem (SVM_{h1}) .

54.1 Soft Margin Support Vector Machines; (SVM_{s1})

In this section we derive the dual function G associated with the following version of the soft margin SVM coming from Problem (SVM_{h1}) , where the maximization of the margin δ has been replaced by the minimization of $-\delta$, and where we added a “regularizing term” $K \left(\sum_{i=1}^p \epsilon_i + \sum_{j=1}^q \xi_j \right)$ whose purpose is to make $\epsilon \in \mathbb{R}^p$ and $\xi \in \mathbb{R}^q$ *sparse* (that is, try to make ϵ_i and ξ_j have as many zeros as possible), where $K > 0$ is a fixed constant that can be

adjusted to determine the influence of this regularizing term. If the primal problem (SVM_{s1}) has an optimal solution $(w, \delta, b, \epsilon, \xi)$, we attempt to use the dual function G to obtain it, but we will see that with this particular formulation of the problem, the constraint $w^\top w \leq 1$ causes troubles even though it is convex.

Soft margin SVM (SVM_{s1}):

$$\text{minimize} \quad -\delta + K \left(\sum_{i=1}^p \epsilon_i + \sum_{j=1}^q \xi_j \right)$$

subject to

$$\begin{aligned} w^\top u_i - b &\geq \delta - \epsilon_i, \quad \epsilon_i \geq 0 \quad i = 1, \dots, p \\ -w^\top v_j + b &\geq \delta - \xi_j, \quad \xi_j \geq 0 \quad j = 1, \dots, q \\ w^\top w &\leq 1. \end{aligned}$$

It is customary to write $\ell = p + q$. Figure 54.2 illustrates the correct margin half space associated with $w^\top x - b - \delta = 0$ while Figure 54.3 illustrates the correct margin half space associated with $w^\top x - b + \delta = 0$. Ideally, all the points should be contained in one of the two correct shifted margin regions described by affine constraints $w^\top u_i - b \geq \delta - \epsilon_i$, or $-w^\top v_j + b \geq \delta - \xi_j$.

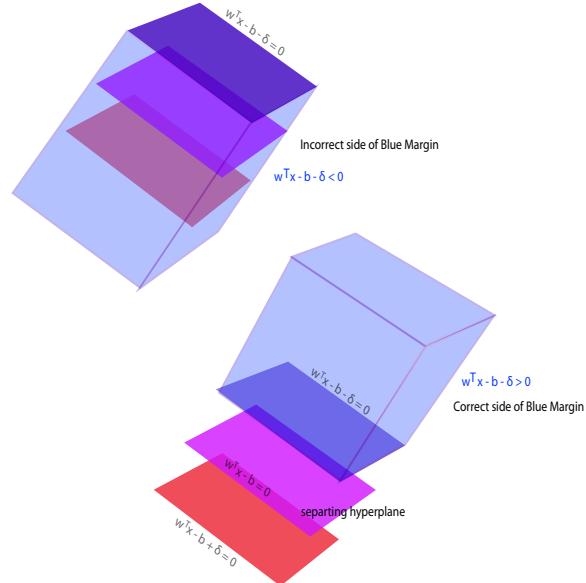

Figure 54.2: The blue margin half space associated with $w^\top x - b - \delta = 0$.

For this problem, the primal problem may have an optimal solution $(w, \delta, b, \epsilon, \xi)$ with $\|w\| = 1$ and $\delta > 0$, but if the sets of points are not linearly separable then an optimal solution of the dual may not yield w .

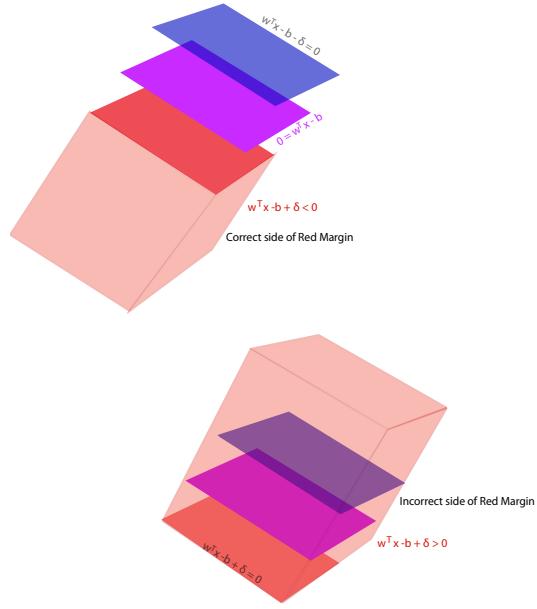

Figure 54.3: The red margin half space associated with $w^\top x - b + \delta = 0$.

The objective function of our problem is affine and the only nonaffine constraint $w^\top w \leq 1$ is convex. This constraint is qualified because for any $w \neq 0$ such that $w^\top w < 1$ and for any $\delta > 0$ and any b we can pick ϵ and ξ large enough so that the constraints are satisfied. Consequently, by Theorem 50.17(2) if the primal problem (SVM_{s1}) has an optimal solution, then the dual problem has a solution too, and the duality gap is zero.

Unfortunately this does not imply that an optimal solution of the dual yields an optimal solution of the primal because the hypotheses of Theorem 50.17(1) fail to hold. In general, there may not be a unique vector $(w, \epsilon, \xi, b, \delta)$ such that

$$\inf_{w, \epsilon, \xi, b, \delta} L(w, \epsilon, \xi, b, \delta, \lambda, \mu, \alpha, \beta, \gamma) = G(\lambda, \mu, \alpha, \beta, \gamma).$$

If the sets $\{u_i\}$ and $\{v_j\}$ are *not* linearly separable, then the dual problem may have a solution for which $\gamma = 0$,

$$\sum_{i=1}^p \lambda_i = \sum_{j=1}^q \mu_j = \frac{1}{2},$$

and

$$\sum_{i=1}^p \lambda_i u_i = \sum_{j=1}^q \mu_j v_j,$$

so that the dual function $G(\lambda, \mu, \alpha, \beta, \gamma)$, which is a *partial function*, is defined and has the value $G(\lambda, \mu, \alpha, \beta, 0) = 0$. Such a pair (λ, μ) corresponds to the coefficients of two convex

combinations

$$\sum_{i=1}^p 2\lambda_i u_i = \sum_{j=1}^q 2\mu_j v_j$$

which correspond to the *same point* in the (nonempty) intersection of the convex hulls $\text{conv}(u_1, \dots, u_p)$ and $\text{conv}(v_1, \dots, v_q)$. It turns out that the only connection between w and the dual function is the equation

$$2\gamma w = \sum_{i=1}^p \lambda_i u_i - \sum_{j=1}^q \mu_j v_j,$$

and when $\gamma = 0$ this is equation is $0 = 0$, so the dual problem is useless to determine w . This point seems to have been missed in the literature (for example, in Shawe–Taylor and Christianini [159], Section 7.2). What the dual problem does show is that $\delta \geq 0$. However, if $\gamma \neq 0$, then w is determined by any solution (λ, μ) of the dual.

It still remains to compute δ and b , which can be done under a mild hypothesis that we call the **Standard Margin Hypothesis**.

Let $\lambda \in \mathbb{R}_+^p$ be the Lagrange multipliers associated with the inequalities $w^\top u_i - b \geq \delta - \epsilon_i$, let $\mu \in \mathbb{R}_+^q$ be the Lagrange multipliers are associated with the inequalities $-w^\top v_j + b \geq \delta - \xi_j$, let $\alpha \in \mathbb{R}_+^p$ be the Lagrange multipliers associated with the inequalities $\epsilon_i \geq 0$, $\beta \in \mathbb{R}_+^q$ be the Lagrange multipliers associated with the inequalities $\xi_j \geq 0$, and let $\gamma \in \mathbb{R}^+$ be the Lagrange multiplier associated with the inequality $w^\top w \leq 1$.

The linear constraints are given by the $2(p+q) \times (n+p+q+2)$ matrix given in block form by

$$C = \begin{pmatrix} X^\top & -I_{p+q} & \mathbf{1}_p & \mathbf{1}_{p+q} \\ 0_{p+q,n} & -I_{p+q} & 0_{p+q} & 0_{p+q} \end{pmatrix},$$

where X is the $n \times (p+q)$ matrix

$$X = (-u_1 \quad \cdots \quad -u_p \quad v_1 \quad \cdots \quad v_q),$$

and the linear constraints are expressed by

$$\begin{pmatrix} X^\top & -I_{p+q} & \mathbf{1}_p & \mathbf{1}_{p+q} \\ 0_{p+q,n} & -I_{p+q} & 0_{p+q} & 0_{p+q} \end{pmatrix} \begin{pmatrix} w \\ \epsilon \\ \xi \\ b \\ \delta \end{pmatrix} \leq \begin{pmatrix} 0_{p+q} \\ 0_{p+q} \end{pmatrix}.$$

More explicitly, C is the following matrix:

$$C = \begin{pmatrix} -u_1^\top & -1 & \cdots & 0 & 0 & \cdots & 0 & 1 & 1 \\ \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\ -u_p^\top & 0 & \cdots & -1 & 0 & \cdots & 0 & 1 & 1 \\ v_1^\top & 0 & \cdots & 0 & -1 & \cdots & 0 & -1 & 1 \\ \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\ v_q^\top & 0 & \cdots & 0 & 0 & \cdots & -1 & -1 & 1 \\ 0 & -1 & \cdots & 0 & 0 & \cdots & 0 & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\ 0 & 0 & \cdots & -1 & 0 & \cdots & 0 & 0 & 0 \\ 0 & 0 & \cdots & 0 & -1 & \cdots & 0 & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\ 0 & 0 & \cdots & 0 & 0 & \cdots & -1 & 0 & 0 \end{pmatrix}.$$

The objective function is given by

$$J(w, \epsilon, \xi, b, \delta) = -\delta + K(\epsilon^\top \xi^\top) \mathbf{1}_{p+q}.$$

The Lagrangian $L(w, \epsilon, \xi, b, \delta, \lambda, \mu, \alpha, \beta, \gamma)$ with $\lambda, \alpha \in \mathbb{R}_+^p$, $\mu, \beta \in \mathbb{R}_+^q$, and $\gamma \in \mathbb{R}^+$ is given by

$$\begin{aligned} L(w, \epsilon, \xi, b, \delta, \lambda, \mu, \alpha, \beta, \gamma) &= -\delta + K(\epsilon^\top \xi^\top) \mathbf{1}_{p+q} \\ &\quad + (w^\top (\epsilon^\top \xi^\top) b \delta) C^\top \begin{pmatrix} \lambda \\ \mu \\ \alpha \\ \beta \end{pmatrix} + \gamma(w^\top w - 1). \end{aligned}$$

Since

$$\begin{aligned} (w^\top (\epsilon^\top \xi^\top) b \delta) C^\top \begin{pmatrix} \lambda \\ \mu \\ \alpha \\ \beta \end{pmatrix} &= w^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - \epsilon^\top (\lambda + \alpha) - \xi^\top (\mu + \beta) + b(\mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu) \\ &\quad + \delta(\mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu), \end{aligned}$$

the Lagrangian can be written as

$$\begin{aligned} L(w, \epsilon, \xi, b, \delta, \lambda, \mu, \alpha, \beta, \gamma) &= -\delta + K(\epsilon^\top \mathbf{1}_p + \xi^\top \mathbf{1}_q) + w^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + \gamma(w^\top w - 1) \\ &\quad - \epsilon^\top (\lambda + \alpha) - \xi^\top (\mu + \beta) + b(\mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu) + \delta(\mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu) \\ &= (\mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu - 1)\delta + w^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + \gamma(w^\top w - 1) \\ &\quad + \epsilon^\top (K\mathbf{1}_p - (\lambda + \alpha)) + \xi^\top (K\mathbf{1}_q - (\mu + \beta)) + b(\mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu). \end{aligned}$$

To find the dual function $G(\lambda, \mu, \alpha, \beta, \gamma)$ we minimize $L(w, \epsilon, \xi, b, \delta, \lambda, \mu, \alpha, \beta, \gamma)$ with respect to w, ϵ, ξ, b , and δ . Since the Lagrangian is convex and $(w, \epsilon, \xi, b, \delta) \in \mathbb{R}^n \times \mathbb{R}^p \times \mathbb{R}^q \times \mathbb{R} \times \mathbb{R}$, a convex open set, by Theorem 40.13, the Lagrangian has a minimum in $(w, \epsilon, \xi, b, \delta)$ iff $\nabla L_{w,\epsilon,\xi,b,\delta} = 0$, so we compute the gradient with respect to $w, \epsilon, \xi, b, \delta$, and we get

$$\nabla L_{w,\epsilon,\xi,b,\delta} = \begin{pmatrix} X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + 2\gamma w \\ K\mathbf{1}_p - (\lambda + \alpha) \\ K\mathbf{1}_q - (\mu + \beta) \\ \mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu \\ \mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu - 1 \end{pmatrix}.$$

By setting $\nabla L_{w,\epsilon,\xi,b,\delta} = 0$ we get the equations

$$\begin{aligned} 2\gamma w &= -X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ \lambda + \alpha &= K\mathbf{1}_p \\ \mu + \beta &= K\mathbf{1}_q \\ \mathbf{1}_p^\top \lambda &= \mathbf{1}_q^\top \mu \\ \mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu &= 1. \end{aligned} \tag{*_w}$$

The second and third equations are equivalent to the inequalities

$$0 \leq \lambda_i, \mu_j \leq K, \quad i = 1, \dots, p, j = 1, \dots, q,$$

often called *box constraints*, and the fourth and fifth equations yield

$$\mathbf{1}_p^\top \lambda = \mathbf{1}_q^\top \mu = \frac{1}{2}.$$

First let us consider the singular case $\gamma = 0$. In this case, $(*_w)$ implies that

$$X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = 0,$$

and the term $\gamma(w^\top w - 1)$ is missing from the Lagrangian, which in view of the other four equations above reduces to

$$L(w, \epsilon, \xi, b, \delta, \lambda, \mu, \alpha, \beta, 0) = w^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = 0.$$

In summary, we proved that if $\gamma = 0$, then

$$G(\lambda, \mu, \alpha, \beta, 0) = \begin{cases} 0 & \text{if } \begin{cases} \sum_{i=1}^p \lambda_i = \sum_{j=1}^q \mu_j = \frac{1}{2} \\ 0 \leq \lambda_i \leq K, i = 1, \dots, p \\ 0 \leq \mu_j \leq K, j = 1, \dots, q \end{cases} \\ -\infty & \text{otherwise} \\ & \text{and } \sum_{i=1}^p \lambda_i u_i - \sum_{j=1}^q \mu_j v_j = 0. \end{cases}$$

Geometrically, (λ, μ) corresponds to the coefficients of two convex combinations

$$\sum_{i=1}^p 2\lambda_i u_i = \sum_{j=1}^q 2\mu_j v_j$$

which correspond to the *same point* in the intersection of the convex hulls $\text{conv}(u_1, \dots, u_p)$ and $\text{conv}(v_1, \dots, v_q)$ iff the sets $\{u_i\}$ and $\{v_j\}$ are *not linearly separable*. If the sets $\{u_i\}$ and $\{v_j\}$ are *linearly separable*, then the convex hulls $\text{conv}(u_1, \dots, u_p)$ and $\text{conv}(v_1, \dots, v_q)$ are disjoint, which implies that $\gamma > 0$.

Let us now assume that $\gamma > 0$. Plugging back w from equation $(*_w)$ into the Lagrangian, after simplifications we get

$$\begin{aligned} G(\lambda, \mu, \alpha, \beta, \gamma) &= -\frac{1}{2\gamma} (\lambda^\top - \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + \frac{\gamma}{4\gamma^2} (\lambda^\top - \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - \gamma \\ &= -\frac{1}{4\gamma} (\lambda^\top - \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - \gamma, \end{aligned}$$

so if $\gamma > 0$ the dual function is independent of α, β and is given by

$$G(\lambda, \mu, \alpha, \beta, \gamma) = \begin{cases} -\frac{1}{4\gamma} (\lambda^\top - \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - \gamma & \text{if } \begin{cases} \sum_{i=1}^p \lambda_i = \sum_{j=1}^q \mu_j = \frac{1}{2} \\ 0 \leq \lambda_i \leq K, i = 1, \dots, p \\ 0 \leq \mu_j \leq K, j = 1, \dots, q \end{cases} \\ -\infty & \text{otherwise.} \end{cases}$$

Since $X^\top X$ is symmetric positive semidefinite and $\gamma \geq 0$, obviously

$$G(\lambda, \mu, \alpha, \beta, \gamma) \leq 0$$

for all $\gamma > 0$.

The dual program is given by

$$\begin{aligned} \text{maximize} \quad & -\frac{1}{4\gamma} (\lambda^\top - \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - \gamma & \text{if } \gamma > 0 \\ & 0 & \text{if } \gamma = 0 \end{aligned}$$

subject to

$$\begin{aligned} \sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j &= 0 \\ \sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j &= 1 \\ 0 \leq \lambda_i &\leq K, \quad i = 1, \dots, p \\ 0 \leq \mu_j &\leq K, \quad j = 1, \dots, q. \end{aligned}$$

Also, if $\gamma = 0$, then $X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = 0$.

Maximizing with respect to $\gamma > 0$ by setting $\frac{\partial}{\partial \gamma} G(\lambda, \mu, \alpha, \beta, \gamma) = 0$ yields

$$\gamma^2 = \frac{1}{4} (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix},$$

so we obtain

$$G(\lambda, \mu) = - \left((\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \right)^{1/2}.$$

Finally, since $G(\lambda, \mu) = 0$ and $X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = 0$ if $\gamma = 0$, the dual program is equivalent to the following minimization program:

Dual of Soft margin SVM (SVM_{s1}):

$$\text{minimize } (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix}$$

subject to

$$\sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j = 0$$

$$\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j = 1$$

$$0 \leq \lambda_i \leq K, \quad i = 1, \dots, p$$

$$0 \leq \mu_j \leq K, \quad j = 1, \dots, q.$$

Observe that the constraints imply that K must be chosen so that

$$K \geq \max \left\{ \frac{1}{2p}, \frac{1}{2q} \right\}.$$

If $(w, \delta, b, \epsilon, \xi)$ is an optimal solution of Problem (SVM_{s1}), then the complementary slackness conditions yield a classification of the points u_i and v_j in terms of the values of λ and μ . Indeed, we have $\epsilon_i \alpha_i = 0$ for $i = 1, \dots, p$ and $\xi_j \beta_j = 0$ for $j = 1, \dots, q$. Also, if $\lambda_i > 0$, then corresponding constraint is active, and similarly if $\mu_j > 0$. Since $\lambda_i + \alpha_i = K$, it follows that $\epsilon_i \alpha_i = 0$ iff $\epsilon_i(K - \lambda_i) = 0$, and since $\mu_j + \beta_j = K$, we have $\xi_j \beta_j = 0$ iff $\xi_j(K - \mu_j) = 0$. Thus if $\epsilon_i > 0$, then $\lambda_i = K$, and if $\xi_j > 0$, then $\mu_j = K$. Consequently, if $\lambda_i < K$, then $\epsilon_i = 0$ and u_i is correctly classified, and similarly if $\mu_j < K$, then $\xi_j = 0$ and v_j is correctly classified. We have the following classification:

(1) If $0 < \lambda_i < K$, then $\epsilon_i = 0$ and the i -th inequality is active, so

$$w^\top u_i - b - \delta = 0.$$

This means that u_i is on the blue margin (the hyperplane $H_{w,b+\delta}$ of equation $w^\top x = b + \delta$) and is classified correctly.

Similarly, if $0 < \mu_j < K$, then $\xi_j = 0$ and

$$w^\top v_j - b + \delta = 0,$$

so v_j is on the red margin (the hyperplane $H_{w,b-\delta}$ of equation $w^\top x = b - \delta$) and is classified correctly. See Figure 54.4.

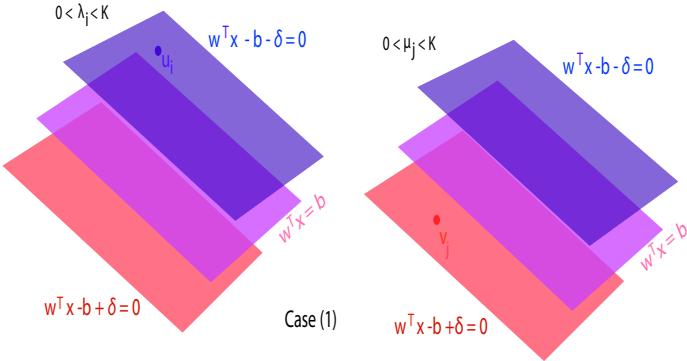

Figure 54.4: When $0 < \lambda_i < K$, u_i is contained within the blue margin hyperplane. When $0 < \mu_j < K$, v_j is contained within the red margin hyperplane.

(2) If $\lambda_i = K$, then the i -th inequality is active, so

$$w^\top u_i - b - \delta = -\epsilon_i.$$

If $\epsilon_i = 0$, then the point u_i is on the blue margin. If $\epsilon_i > 0$, then u_i is within the open half space bounded by the blue margin hyperplane $H_{w,b+\delta}$ and containing the separating hyperplane $H_{w,b}$; if $\epsilon_i \leq \delta$, then u_i is classified correctly, and if $\epsilon_i > \delta$, then u_i is misclassified (u_i lies on the wrong side of the separating hyperplane, the red side). See Figure 54.5.

Similarly, if $\mu_j = K$, then

$$w^\top v_j - b + \delta = \xi_j.$$

If $\xi_j = 0$, then the point v_j is on the red margin. If $\xi_j > 0$, then v_j is within the open half space bounded by the red margin hyperplane $H_{w,b-\delta}$ and containing the

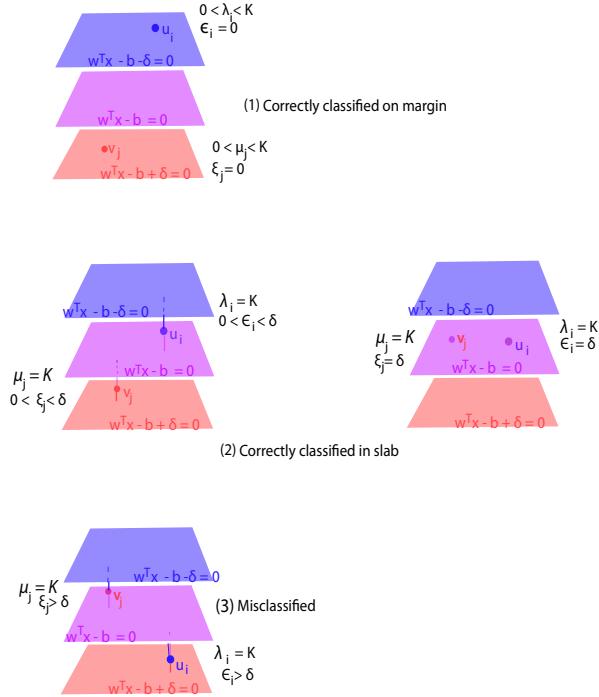

Figure 54.5: Figure (1) illustrates the case of u_i contained in the margin and occurs when $\epsilon_i = 0$. Figure (1) also illustrates the case of v_j contained in the margin when $\xi_j = 0$. The left illustration of Figure (2) is when u_i is inside the margin yet still on the correct side of the separating hyperplane $w^T x - b = 0$. Similarly, v_j is inside the margin on the correct side of the separating hyperplane. The right illustration depicts u_i and v_j on the separating hyperplane. Figure (3) illustrates a misclassification of u_i and v_j .

separating hyperplane $H_{w,b}$; if $\xi_j \leq \delta$, then v_j is classified correctly, and if $\xi_j > \delta$, then v_j is misclassified (v_j lies on the wrong side of the separating hyperplane, the blue side). See Figure 54.5.

- (3) If $\lambda_i = 0$, then $\epsilon_i = 0$ and the i -th inequality may or may not be active, so

$$w^T u_i - b - \delta \geq 0.$$

Thus u_i is in the closed half space on the blue side bounded by the blue margin hyperplane $H_{w,b+\delta}$ (of course, classified correctly).

Similarly, if $\mu_j = 0$, then

$$w^T v_j - b + \delta \leq 0$$

and v_j is in the closed half space on the red side bounded by the red margin hyperplane $H_{w,b-\delta}$ (of course, classified correctly). See Figure 54.6.

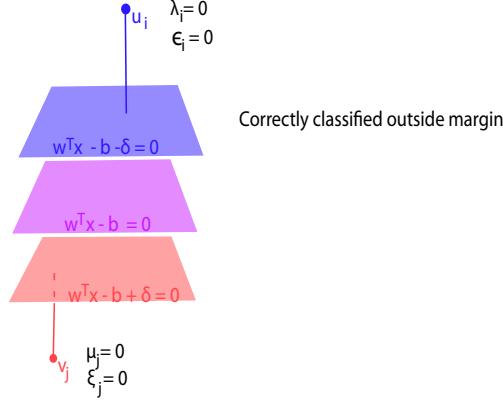

Figure 54.6: When $\lambda_i = 0$, u_i is correctly classified outside the blue margin. When $\mu_j = 0$, v_j is correctly classified outside the red margin.

Definition 54.1. The vectors u_i on the blue margin $H_{w,b+\delta}$ and the vectors v_j on the red margin $H_{w,b-\delta}$ are called *support vectors*. Support vectors correspond to vectors u_i for which $w^\top u_i - b - \delta = 0$ (which implies $\epsilon_i = 0$), and vectors v_j for which $w^\top v_j - b + \delta = 0$ (which implies $\xi_j = 0$). Support vectors u_i such that $0 < \lambda_i < K$ and support vectors v_j such that $0 < \mu_j < K$ are *support vectors of type 1*. Support vectors of type 1 play a special role so we denote the sets of indices associated with them by

$$\begin{aligned} I_\lambda &= \{i \in \{1, \dots, p\} \mid 0 < \lambda_i < K\} \\ I_\mu &= \{j \in \{1, \dots, q\} \mid 0 < \mu_j < K\}. \end{aligned}$$

We denote their cardinalities by $numsvl_1 = |I_\lambda|$ and $numsvm_1 = |I_\mu|$. Support vectors u_i such that $\lambda_i = K$ and support vectors v_j such that $\mu_j = K$ are *support vectors of type 2*. Those support vectors u_i such that $\lambda_i = 0$ and those support vectors v_j such that $\mu_j = 0$ are called *exceptional support vectors*.

The vectors u_i for which $\lambda_i = K$ and the vectors v_j for which $\mu_j = K$ are said to *fail the margin*. The sets of indices associated with the vectors failing the margin are denoted by

$$\begin{aligned} K_\lambda &= \{i \in \{1, \dots, p\} \mid \lambda_i = K\} \\ K_\mu &= \{j \in \{1, \dots, q\} \mid \mu_j = K\}. \end{aligned}$$

We denote their cardinalities by $p_f = |K_\lambda|$ and $q_f = |K_\mu|$.

Vectors u_i such that $\lambda_i > 0$ and vectors v_j such that $\mu_j > 0$ are said to *have margin at most δ* . The sets of indices associated with these vectors are denoted by

$$\begin{aligned} I_{\lambda>0} &= \{i \in \{1, \dots, p\} \mid \lambda_i > 0\} \\ I_{\mu>0} &= \{j \in \{1, \dots, q\} \mid \mu_j > 0\}. \end{aligned}$$

We denote their cardinalities by $p_m = |I_{\lambda>0}|$ and $q_m = |I_{\mu>0}|$.

Obviously, $I_{\lambda>0} = I_\lambda \cup K_\lambda$ and $I_{\mu>0} = I_\mu \cup K_\mu$, so $p_f \leq p_m$ and $q_f \leq q_m$. *Intuitively a blue point that fails the margin is on the wrong side of the blue margin and a red point that fails the margin is on the wrong side of the red margin.* The points in $I_{\lambda>0}$ not in K_λ are on the blue margin and the points in $I_{\mu>0}$ not in K_μ are on the red margin. There are $p - p_m$ points u_i classified correctly on the blue side and outside the δ -slab and there are $q - q_m$ points v_j classified correctly on the red side and outside the δ -slab.

It is easy to show that we have the following bounds on K :

$$\max \left\{ \frac{1}{2p_m}, \frac{1}{2q_m} \right\} \leq K \leq \min \left\{ \frac{1}{2p_f}, \frac{1}{2q_f} \right\}.$$

These inequalities restrict the choice of K quite heavily.

It will also be useful to understand how points are classified in terms of ϵ_i (or ξ_j).

- (1) If $\epsilon_i > 0$, then by complementary slackness $\lambda_i = K$, so the i th equation is active and by (2) above,

$$w^\top u_i - b - \delta = -\epsilon_i.$$

Since $\epsilon_i > 0$, the point u_i is within the open half space bounded by the blue margin hyperplane $H_{w,b+\delta}$ and containing the separating hyperplane $H_{w,b}$; if $\epsilon_i \leq \delta$, then u_i is classified correctly, and if $\epsilon_i > \delta$, then u_i is misclassified.

Similarly, if $\xi_j > 0$, then v_j is within the open half space bounded by the red margin hyperplane $H_{w,b-\delta}$ and containing the separating hyperplane $H_{w,b}$; if $\xi_j \leq \delta$, then v_j is classified correctly, and if $\xi_j > \delta$, then v_j is misclassified.

- (2) If $\epsilon_i = 0$, then the point u_i is correctly classified. If $\lambda_i = 0$, then by (3) above, u_i is in the closed half space on the blue side bounded by the blue margin hyperplane $H_{w,b+\delta}$. If $\lambda_i > 0$, then by (1) and (2) above, the point u_i is on the blue margin.

Similarly, if $\xi_j = 0$, then the point v_j is correctly classified. If $\mu_j = 0$, then v_j is in the closed half space on the red side bounded by the red margin hyperplane $H_{w,b-\delta}$, and if $\mu_j > 0$, then the point v_j is on the red margin.

It shown in Section 54.2 how the dual program is solved using ADMM from Section 52.6. If the primal problem is solvable, this yields solutions for λ and μ .

If the optimal value is 0, then $\gamma = 0$ and $X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = 0$, so in this case it is not possible to determine w . However, if the optimal value is > 0 , then once a solution for λ and μ is obtained, by $(*_w)$, we have

$$\begin{aligned} \gamma &= \frac{1}{2} \left((\lambda^\top \quad \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \right)^{1/2} \\ w &= \frac{1}{2\gamma} \left(\sum_{i=1}^p \lambda_i u_i - \sum_{j=1}^q \mu_j v_j \right), \end{aligned}$$

so we get

$$w = \frac{\sum_{i=1}^p \lambda_i u_i - \sum_{j=1}^q \mu_j v_j}{\left((\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \right)^{1/2}},$$

which is the result of making $\sum_{i=1}^p \lambda_i u_i - \sum_{j=1}^q \mu_j v_j$ a unit vector, since

$$X = \begin{pmatrix} -u_1 & \cdots & -u_p & v_1 & \cdots & v_q \end{pmatrix}.$$

It remains to find b and δ , which are not given by the dual program and for this we use the complementary slackness conditions.

The equations

$$\sum_{i=1}^p \lambda_i = \sum_{j=1}^q \mu_j = \frac{1}{2}$$

imply that there is some i_0 such that $\lambda_{i_0} > 0$ and some j_0 such that $\mu_{j_0} > 0$, but a priori, nothing prevents the situation where $\lambda_i = K$ for all nonzero λ_i or $\mu_j = K$ for all nonzero μ_j . If this happens, we can rerun the optimization method with a larger value of K . If the following mild hypothesis holds, then b and δ can be found.

Standard Margin Hypothesis for (SVM_{s1}) . There is some index i_0 such that $0 < \lambda_{i_0} < K$ and there is some index j_0 such that $0 < \mu_{j_0} < K$. This means that some u_{i_0} is a support vector of type 1 on the blue margin, and some v_{j_0} is a support of type 1 on the red margin.

If the **Standard Margin Hypothesis** for (SVM_{s1}) holds, then $\epsilon_{i_0} = 0$ and $\mu_{j_0} = 0$, and then we have the active equations

$$w^\top u_{i_0} - b = \delta \quad \text{and} \quad -w^\top v_{j_0} + b = \delta,$$

and we obtain the values of b and δ as

$$\begin{aligned} b &= \frac{1}{2}(w^\top u_{i_0} + w^\top v_{j_0}) \\ \delta &= \frac{1}{2}(w^\top u_{i_0} - w^\top v_{j_0}). \end{aligned}$$

Due to numerical instability, when writing a computer program it is preferable to compute the lists of indices I_λ and I_μ given by

$$\begin{aligned} I_\lambda &= \{i \in \{1, \dots, p\} \mid 0 < \lambda_i < K\} \\ I_\mu &= \{j \in \{1, \dots, q\} \mid 0 < \mu_j < K\}. \end{aligned}$$

Then it is easy to see that we can compute b and δ using the following averaging formulae:

$$\begin{aligned} b &= w^\top \left(\left(\sum_{i \in I_\lambda} u_i \right) / |I_\lambda| + \left(\sum_{j \in I_\mu} v_j \right) / |I_\mu| \right) / 2 \\ \delta &= w^\top \left(\left(\sum_{i \in I_\lambda} u_i \right) / |I_\lambda| - \left(\sum_{j \in I_\mu} v_j \right) / |I_\mu| \right) / 2. \end{aligned}$$

As we said earlier, the hypotheses of Theorem 50.17(2) hold, so *if* the primal problem (SVM_{s1}) has an optimal solution with $w \neq 0$, *then* the dual problem has a solution too, and the duality gap is zero. Therefore, for optimal solutions we have

$$L(w, \epsilon, \xi, b, \delta, \lambda, \mu, \alpha, \beta, \gamma) = G(\lambda, \mu, \alpha, \beta, \gamma),$$

which means that

$$-\delta + K \left(\sum_{i=1}^p \epsilon_i + \sum_{j=1}^q \xi_j \right) = - \left((\lambda^\top \ \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \right)^{1/2},$$

so we get

$$\delta = K \left(\sum_{i=1}^p \epsilon_i + \sum_{j=1}^q \xi_j \right) + \left((\lambda^\top \ \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \right)^{1/2}.$$

Therefore, we confirm that $\delta \geq 0$.

It is important to note that the objective function of the dual program

$$-G(\lambda, \mu) = \left((\lambda^\top \ \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \right)^{1/2}$$

only involves the inner products of the u_i and the v_j through the matrix $X^\top X$, and similarly, the equation of the optimal hyperplane can be written as

$$\sum_{i=1}^p \lambda_i u_i^\top x - \sum_{j=1}^q \mu_j v_j^\top x - \left((\lambda^\top \ \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \right)^{1/2} b = 0,$$

an expression that only involves inner products of x with the u_i and the v_j and inner products of the u_i and the v_j .

As explained at the beginning of this chapter, this is a key fact that allows a generalization of the support vector machine using the method of *kernels*. We can define the following “kernelized” version of Problem (SVM_{s1}):

Soft margin kernel SVM (SVM_{s1}):

$$\begin{aligned} \text{minimize} \quad & -\delta + K \left(\sum_{i=1}^p \epsilon_i + \sum_{j=1}^q \xi_j \right) \\ \text{subject to} \quad & \langle w, \varphi(u_i) \rangle - b \geq \delta - \epsilon_i, \quad \epsilon_i \geq 0 \quad i = 1, \dots, p \\ & -\langle w, \varphi(v_j) \rangle + b \geq \delta - \xi_j, \quad \xi_j \geq 0 \quad j = 1, \dots, q \\ & \langle w, w \rangle \leq 1. \end{aligned}$$

Tracing through the computation that led us to the dual program with u_i replaced by $\varphi(u_i)$ and v_j replaced by $\varphi(v_j)$, we find the following version of the dual program:

Dual of Soft margin kernel SVM (SVM_{s1}):

$$\begin{aligned} \text{minimize} \quad & (\lambda^\top \mu^\top) \mathbf{K} \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ \text{subject to} \quad & \sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j = 0 \\ & \sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j = 1 \\ & 0 \leq \lambda_i \leq K, \quad i = 1, \dots, p \\ & 0 \leq \mu_j \leq K, \quad j = 1, \dots, q, \end{aligned}$$

where \mathbf{K} is the $\ell \times \ell$ kernel symmetric matrix (with $\ell = p + q$) given by

$$\mathbf{K}_{ij} = \begin{cases} \kappa(u_i, u_j) & 1 \leq i \leq p, 1 \leq j \leq q \\ -\kappa(u_i, v_{j-p}) & 1 \leq i \leq p, p+1 \leq j \leq p+q \\ -\kappa(v_{i-p}, u_j) & p+1 \leq i \leq p+q, 1 \leq j \leq p \\ \kappa(v_{i-p}, v_{j-q}) & p+1 \leq i \leq p+q, p+1 \leq j \leq p+q. \end{cases}$$

We also find that

$$w = \frac{\sum_{i=1}^p \lambda_i \varphi(u_i) - \sum_{j=1}^q \mu_j \varphi(v_j)}{\left((\lambda^\top \mu^\top) K \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \right)^{1/2}}.$$

Under the Standard Margin Hypothesis, there is some index i_0 such that $0 < \lambda_{i_0} < K$ and there is some index j_0 such that $0 < \mu_{j_0} < K$, and we obtain the value of b and δ as

$$\begin{aligned} b &= \frac{1}{2}(\langle w, \varphi(u_{i_0}) \rangle + \langle w, \varphi(v_{j_0}) \rangle) \\ \delta &= \frac{1}{2}(\langle w, \varphi(u_{i_0}) \rangle - \langle w, \varphi(v_{j_0}) \rangle). \end{aligned}$$

Using the above value for w , we obtain

$$b = \frac{\sum_{i=1}^p \lambda_i (\kappa(u_i, u_{i_0}) + \kappa(u_i, v_{j_0})) - \sum_{j=1}^q \mu_j (\kappa(v_j, u_{i_0}) + \kappa(v_j, v_{j_0}))}{2 \left((\lambda^\top \mu^\top) K \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \right)^{1/2}}.$$

It follows that the classification function

$$f(x) = \text{sgn}(\langle w, \varphi(x) \rangle - b)$$

is given by

$$\begin{aligned} f(x) &= \text{sgn} \left(\sum_{i=1}^p \lambda_i (2\kappa(u_i, x) - \kappa(u_i, u_{i_0}) - \kappa(u_i, v_{j_0})) \right. \\ &\quad \left. - \sum_{j=1}^q \mu_j (2\kappa(v_j, x) - \kappa(v_j, u_{i_0}) - \kappa(v_j, v_{j_0})) \right), \end{aligned}$$

which is solely expressed in terms of the kernel κ .

Kernel methods for SVM are discussed in Schölkopf and Smola [145] and Shawe-Taylor and Christianini [159].

54.2 Solving SVM (SVM_{s1}) Using ADMM

In order to solve (SVM_{s1}) using ADMM we need to write the matrix corresponding to the constraints in equational form,

$$\begin{aligned} \sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j &= 0 \\ \sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j &= 1 \\ \lambda_i + \alpha_i &= K, \quad i = 1, \dots, p \\ \mu_j + \beta_j &= K, \quad j = 1, \dots, q. \end{aligned}$$

This is the $(p+q+2) \times 2(p+q)$ matrix A given by

$$A = \begin{pmatrix} \mathbf{1}_p^\top & -\mathbf{1}_q^\top & 0_p^\top & 0_q^\top \\ \mathbf{1}_p^\top & \mathbf{1}_q^\top & 0_p^\top & 0_q^\top \\ I_p & 0_{p,q} & I_p & 0_{p,q} \\ 0_{q,p} & I_q & 0_{q,p} & I_q \end{pmatrix}.$$

We leave it as an exercise to prove that A has rank $p+q+2$. The right-hand side is

$$c = \begin{pmatrix} 0 \\ 1 \\ K\mathbf{1}_{p+q} \end{pmatrix}.$$

The symmetric positive semidefinite $(p+q) \times (p+q)$ matrix P defining the quadratic functional is

$$P = 2X^\top X, \quad \text{with} \quad X = (-u_1 \ \cdots \ -u_p \ v_1 \ \cdots \ v_q),$$

and

$$q = 0_{p+q}.$$

Since there are $2(p+q)$ Lagrange multipliers $(\lambda, \mu, \alpha, \beta)$, the $(p+q) \times (p+q)$ matrix $X^\top X$ must be augmented with zero's to make it a $2(p+q) \times 2(p+q)$ matrix P_a given by

$$P_a = \begin{pmatrix} X^\top X & 0_{p+q,p+q} \\ 0_{p+q,p+q} & 0_{p+q,p+q} \end{pmatrix},$$

and similarly q is augmented with zeros as the vector $q_a = 0_{2(p+q)}$.

Since the constraint $w^\top w \leq 1$ causes troubles, we trade it for a different objective function in which $-\delta$ is replaced by $(1/2)\|w\|_2^2$. This way we are left with purely affine constraints. In the next section we discuss a generalization of Problem (SVM _{$h2$}) obtained by adding a linear regularizing term.

54.3 Soft Margin Support Vector Machines; (SVM _{$s2$})

In this section we consider the generalization of Problem (SVM _{$h2$}) where we minimize $(1/2)w^\top w$ by adding the “regularizing term” $K\left(\sum_{i=1}^p \epsilon_i + \sum_{j=1}^q \xi_j\right)$ for some $K > 0$. Recall that the margin δ is given by $\delta = 1/\|w\|$.

Soft margin SVM (SVM _{$s2$}):

$$\text{minimize} \quad \frac{1}{2}w^\top w + K(\epsilon^\top \xi^\top) \mathbf{1}_{p+q}$$

subject to

$$\begin{aligned} w^\top u_i - b &\geq 1 - \epsilon_i, & \epsilon_i \geq 0 && i = 1, \dots, p \\ -w^\top v_j + b &\geq 1 - \xi_j, & \xi_j \geq 0 && j = 1, \dots, q. \end{aligned}$$

This is the classical problem discussed in all books on machine learning or pattern analysis, for instance Vapnik [182], Bishop [23], and Shawe-Taylor and Christianini [159]. The trivial solution where all variables are 0 is ruled out because of the presence of the 1 in the inequalities, but it is not clear that if (w, ϵ, ξ) is an optimal solution, then $w \neq 0$.

We prove that if the primal problem has an optimal solution (w, ϵ, ξ, b) with $w \neq 0$, then w is determined by any optimal solution (λ, μ) of the dual. We also prove that there is some i for which $\lambda_i > 0$ and some j for which $\mu_j > 0$. Under a mild hypothesis that we call the **Standard Margin Hypothesis**, b can be found.

Note that this framework is still somewhat sensitive to outliers because the penalty for misclassification is linear in ϵ and ξ .

First we write the constraints in matrix form. The $2(p+q) \times (n+p+q+1)$ matrix C is written in block form as

$$C = \begin{pmatrix} X^\top & -I_{p+q} & \mathbf{1}_p \\ 0_{p+q,n} & -I_{p+q} & 0_{p+q} \end{pmatrix},$$

where X is the $n \times (p+q)$ matrix

$$X = (-u_1 \ \cdots \ -u_p \ v_1 \ \cdots \ v_q),$$

and the constraints are expressed by

$$\begin{pmatrix} X^\top & -I_{p+q} & \mathbf{1}_p \\ 0_{p+q,n} & -I_{p+q} & 0_{p+q} \end{pmatrix} \begin{pmatrix} w \\ \epsilon \\ \xi \\ b \end{pmatrix} \leq \begin{pmatrix} \mathbf{0}_{p+q} \\ 0_{p+q} \end{pmatrix}.$$

The objective function $J(w, \epsilon, \xi, b)$ is given by

$$J(w, \epsilon, \xi, b) = \frac{1}{2} w^\top w + K(\epsilon^\top \ \xi^\top) \mathbf{1}_{p+q}.$$

The Lagrangian $L(w, \epsilon, \xi, b, \lambda, \mu, \alpha, \beta)$ with $\lambda, \alpha \in \mathbb{R}_+^p$ and with $\mu, \beta \in \mathbb{R}_+^q$ is given by

$$\begin{aligned} L(w, \epsilon, \xi, b, \lambda, \mu, \alpha, \beta) &= \frac{1}{2} w^\top w + K(\epsilon^\top \ \xi^\top) \mathbf{1}_{p+q} \\ &\quad + (w^\top \ (\epsilon^\top \ \xi^\top) \ b) C^\top \begin{pmatrix} \lambda \\ \mu \\ \alpha \\ \beta \end{pmatrix} + (\mathbf{1}_{p+q}^\top \ 0_{p+q}^\top) \begin{pmatrix} \lambda \\ \mu \\ \alpha \\ \beta \end{pmatrix}. \end{aligned}$$

Since

$$(w^\top \ (\epsilon^\top \ \xi^\top) \ b) C^\top \begin{pmatrix} \lambda \\ \mu \\ \alpha \\ \beta \end{pmatrix} = (w^\top \ (\epsilon^\top \ \xi^\top) \ b) \begin{pmatrix} X & 0_{n,p+q} \\ -I_{p+q} & -I_{p+q} \\ \mathbf{1}_p^\top & -\mathbf{1}_q^\top \\ 0_{p+q}^\top \end{pmatrix} \begin{pmatrix} \lambda \\ \mu \\ \alpha \\ \beta \end{pmatrix},$$

we get

$$\begin{aligned} (w^\top \ (\epsilon^\top \ \xi^\top) \ b) C^\top \begin{pmatrix} \lambda \\ \mu \\ \alpha \\ \beta \end{pmatrix} &= (w^\top \ (\epsilon^\top \ \xi^\top) \ b) \begin{pmatrix} X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ - \begin{pmatrix} \lambda + \alpha \\ \mu + \beta \end{pmatrix} \\ \mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu \end{pmatrix} \\ &= w^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - \epsilon^\top (\lambda + \alpha) - \xi^\top (\mu + \beta) + b(\mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu), \end{aligned}$$

and since

$$(\mathbf{1}_{p+q}^\top \ 0_{p+q}^\top) \begin{pmatrix} \lambda \\ \mu \\ \alpha \\ \beta \end{pmatrix} = \mathbf{1}_{p+q}^\top \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = (\lambda^\top \ \mu^\top) \mathbf{1}_{p+q},$$

the Lagrangian can be rewritten as

$$\begin{aligned} L(w, \epsilon, \xi, b, \lambda, \mu, \alpha, \beta) &= \frac{1}{2} w^\top w + w^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + \epsilon^\top (K \mathbf{1}_p - (\lambda + \alpha)) + \xi^\top (K \mathbf{1}_q - (\mu + \beta)) \\ &\quad + b(\mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu) + (\lambda^\top \ \mu^\top) \mathbf{1}_{p+q}. \end{aligned}$$

To find the dual function $G(\lambda, \mu, \alpha, \beta)$ we minimize $L(w, \epsilon, \xi, b, \lambda, \mu, \alpha, \beta)$ with respect to w, ϵ, ξ and b . Since the Lagrangian is convex and $(w, \epsilon, \xi, b) \in \mathbb{R}^n \times \mathbb{R}^p \times \mathbb{R}^q \times \mathbb{R}$, a convex open set, by Theorem 40.13, the Lagrangian has a minimum in (w, ϵ, ξ, b) iff $\nabla L_{w,\epsilon,\xi,b} = 0$, so we compute its gradient with respect to w, ϵ, ξ and b , and we get

$$\nabla L_{w,\epsilon,\xi,b} = \begin{pmatrix} w + X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ K \mathbf{1}_p - (\lambda + \alpha) \\ K \mathbf{1}_q - (\mu + \beta) \\ \mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu \end{pmatrix}.$$

By setting $\nabla L_{w,\epsilon,\xi,b} = 0$ we get the equations

$$\begin{aligned} w &= -X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} & (*_w) \\ \lambda + \alpha &= K \mathbf{1}_p \\ \mu + \beta &= K \mathbf{1}_q \\ \mathbf{1}_p^\top \lambda &= \mathbf{1}_q^\top \mu. \end{aligned}$$

The first and the fourth equation are identical to the Equations (*₁) and (*₂) that we obtained in Example 50.10. Since $\lambda, \mu, \alpha, \beta \geq 0$, the second and the third equation are equivalent to the box constraints

$$0 \leq \lambda_i, \mu_j \leq K, \quad i = 1, \dots, p, \quad j = 1, \dots, q.$$

Using the equations that we just derived, after simplifications we get

$$G(\lambda, \mu, \alpha, \beta) = -\frac{1}{2} (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + (\lambda^\top \mu^\top) \mathbf{1}_{p+q},$$

which is independent of α and β and is identical to the dual function obtained in (*₄) of Example 50.10. To be perfectly rigorous,

$$G(\lambda, \mu) = \begin{cases} -\frac{1}{2} (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + (\lambda^\top \mu^\top) \mathbf{1}_{p+q} & \text{if } \begin{cases} \sum_{i=1}^p \lambda_i = \sum_{j=1}^q \mu_j \\ 0 \leq \lambda_i \leq K, \quad i = 1, \dots, p \\ 0 \leq \mu_j \leq K, \quad j = 1, \dots, q \end{cases} \\ -\infty & \text{otherwise.} \end{cases}$$

As in Example 50.10, the the dual program can be formulated as

$$\text{maximize} \quad -\frac{1}{2} (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + (\lambda^\top \mu^\top) \mathbf{1}_{p+q}$$

subject to

$$\sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j = 0$$

$$0 \leq \lambda_i \leq K, \quad i = 1, \dots, p$$

$$0 \leq \mu_j \leq K, \quad j = 1, \dots, q,$$

or equivalently

Dual of Soft margin SVM (SVM_{s2}):

$$\text{minimize} \quad \frac{1}{2} (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - (\lambda^\top \mu^\top) \mathbf{1}_{p+q}$$

subject to

$$\sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j = 0$$

$$0 \leq \lambda_i \leq K, \quad i = 1, \dots, p$$

$$0 \leq \mu_j \leq K, \quad j = 1, \dots, q.$$

If (w, ϵ, ξ, b) is an optimal solution of Problem (SVM_{s2}), then the complementary slackness conditions yield a classification of the points u_i and v_j in terms of the values of λ and μ .

Indeed, we have $\epsilon_i \alpha_i = 0$ for $i = 1, \dots, p$ and $\xi_j \beta_j = 0$ for $j = 1, \dots, q$. Also, if $\lambda_i > 0$, then corresponding constraint is active, and similarly if $\mu_j > 0$. Since $\lambda_i + \alpha_i = K$, it follows that $\epsilon_i \alpha_i = 0$ iff $\epsilon_i(K - \lambda_i) = 0$, and since $\mu_j + \beta_j = K$, we have $\xi_j \beta_j = 0$ iff $\xi_j(K - \mu_j) = 0$. Thus if $\epsilon_i > 0$, then $\lambda_i = K$, and if $\xi_j > 0$, then $\mu_j = K$. Consequently, if $\lambda_i < K$, then $\epsilon_i = 0$ and u_i is correctly classified, and similarly if $\mu_j < K$, then $\xi_j = 0$ and v_j is correctly classified.

We have a classification of the points u_i and v_j in terms of λ and μ obtained from the classification given in Section 54.1 by replacing δ with 1. Since it is so similar, it is omitted. Let us simply recall that the vectors u_i on the blue margin and the vectors v_j on the red margin are called *support vectors*; these are the vectors u_i for which $w^\top u_i - b - 1 = 0$ (which implies $\epsilon_i = 0$), and the vectors v_j for which $w^\top v_j - b + 1 = 0$ (which implies $\xi_j = 0$). Those support vectors u_i such that $\lambda_i = 0$ and those support vectors such that $\mu_j = 0$ are called *exceptional support vectors*.

We also have the following classification of the points u_i and v_j terms of ϵ_i (or ξ_j) obtained by replacing δ with 1.

- (1) If $\epsilon_i > 0$, then by complementary slackness $\lambda_i = K$, so the i th equation is active and by (2) above,

$$w^\top u_i - b - 1 = -\epsilon_i.$$

Since $\epsilon_i > 0$, the point u_i is within the open half space bounded by the blue margin hyperplane $H_{w,b+1}$ and containing the separating hyperplane $H_{w,b}$; if $\epsilon_i \leq 1$, then u_i is classified correctly, and if $\epsilon_i > 1$, then u_i is misclassified.

Similarly, if $\xi_j > 0$, then v_j is within the open half space bounded by the red margin hyperplane $H_{w,b-1}$ and containing the separating hyperplane $H_{w,b}$; if $\xi_j \leq 1$, then v_j is classified correctly, and if $\xi_j > 1$, then v_j is misclassified.

- (2) If $\epsilon_i = 0$, then the point u_i is correctly classified. If $\lambda_i = 0$, then by (3) above, u_i is in the closed half space on the blue side bounded by the blue margin hyperplane $H_{w,b+\eta}$. If $\lambda_i > 0$, then by (1) and (2) above, the point u_i is on the blue margin.

Similarly, if $\xi_j = 0$, then the point v_j is correctly classified. If $\mu_j = 0$, then v_j is in the closed half space on the red side bounded by the red margin hyperplane $H_{w,b-\eta}$, and if $\mu_j > 0$, then the point v_j is on the red margin. See Figure 54.5 (3).

Vectors u_i for which $\lambda_i = K$ and vectors v_j such that $\xi_j = K$ are said to *fail the margin*.

It is shown in Section 54.4 how the dual program is solved using ADMM from Section 52.6. If the primal problem is solvable, this yields solutions for λ and μ .

Remark: The hard margin Problem (SVM_{h2}) corresponds to the special case of Problem (SVM_{s2}) in which $\epsilon = 0$, $\xi = 0$, and $K = +\infty$. Indeed, in Problem (SVM_{h2}) the terms

involving ϵ and ξ are missing from the Lagrangian and the effect is that the box constraints are missing; we simply have $\lambda_i \geq 0$ and $\mu_j \geq 0$.

We can use the dual program to solve the primal. Once $\lambda \geq 0, \mu \geq 0$ have been found, w is given by

$$w = -X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = \sum_{i=1}^p \lambda_i u_i - \sum_{j=1}^q \mu_j v_j.$$

To find b we use the complementary slackness conditions.

If the primal has a solution $w \neq 0$, then the equation

$$w = \sum_{i=1}^p \lambda_i u_i - \sum_{j=1}^q \mu_j v_j$$

implies that either there is some index i_0 such that $\lambda_{i_0} > 0$ or there is some index j_0 such that $\mu_{j_0} > 0$. The constraint

$$\sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j = 0$$

implies that there is some index i_0 such that $\lambda_{i_0} > 0$ and there is some index j_0 such that $\mu_{j_0} > 0$. However, a priori, nothing prevents the situation where $\lambda_i = K$ for all nonzero λ_i or $\mu_j = K$ for all nonzero μ_j . If this happens, we can rerun the optimization method with a larger value of K . Observe that the equation

$$\sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j = 0$$

implies that if there is some index i_0 such that $0 < \lambda_{i_0} < K$, then there is some index j_0 such that $0 < \mu_{j_0} < K$, and vice-versa. If the following mild hypothesis holds, then b can be found.

Standard Margin Hypothesis for (SVM_{s2}). There is some index i_0 such that $0 < \lambda_{i_0} < K$ and there is some index j_0 such that $0 < \mu_{j_0} < K$. This means that some u_{i_0} is a support vector of type 1 on the blue margin, and some v_{j_0} is a support vector of type 1 on the red margin.

If the **Standard Margin Hypothesis** for (SVM_{s2}) holds, then $\epsilon_{i_0} = 0$ and $\mu_{j_0} = 0$, and then we have the active equations

$$w^\top u_{i_0} - b = 1 \quad \text{and} \quad -w^\top v_{j_0} + b = 1,$$

and we obtain

$$b = \frac{1}{2}(w^\top u_{i_0} + w^\top v_{j_0}).$$

Due to numerical instability, when writing a computer program it is preferable to compute the lists of indices I_λ and I_μ given by

$$\begin{aligned} I_\lambda &= \{i \in \{1, \dots, p\} \mid 0 < \lambda_i < K\} \\ I_\mu &= \{j \in \{1, \dots, q\} \mid 0 < \mu_j < K\}. \end{aligned}$$

Then it is easy to see that we can compute b using the following averaging formula

$$b = w^\top \left(\left(\sum_{i \in I_\lambda} u_i \right) / |I_\lambda| + \left(\sum_{j \in I_\mu} v_j \right) / |I_\mu| \right) / 2.$$

Recall that $\delta = 1/\|w\|$.

Remark: There is a cheap version of Problem (SVM_{s2}) which consists in dropping the term $(1/2)w^\top w$ from the objective function:

Soft margin classifier (SVM_{s2l}):

$$\begin{aligned} \text{minimize} \quad & \sum_{i=1}^p \epsilon_i + \sum_{j=1}^q \xi_j \\ \text{subject to} \quad & w^\top u_i - b \geq 1 - \epsilon_i, \quad \epsilon_i \geq 0 \quad i = 1, \dots, p \\ & -w^\top v_j + b \geq 1 - \xi_j, \quad \xi_j \geq 0 \quad j = 1, \dots, q. \end{aligned}$$

The above program is a linear program that minimizes the number of misclassified points but does not care about enforcing a minimum margin. An example of its use is given in Boyd and Vandenberghe; see [29], Section 8.6.1.

The “kernelized” version of Problem (SVM_{s2}) is the following:

Soft margin kernel SVM (SVM_{s2}):

$$\begin{aligned} \text{minimize} \quad & \frac{1}{2} \langle w, w \rangle + K(\epsilon^\top \xi^\top) \mathbf{1}_{p+q} \\ \text{subject to} \quad & \langle w, \varphi(u_i) \rangle - b \geq 1 - \epsilon_i, \quad \epsilon_i \geq 0 \quad i = 1, \dots, p \\ & -\langle w, \varphi(v_j) \rangle + b \geq 1 - \xi_j, \quad \xi_j \geq 0 \quad j = 1, \dots, q. \end{aligned}$$

Redoing the computation of the dual function, we find that the dual program is given by

Dual of Soft margin kernel SVM (SVM_{s2}):

$$\text{minimize} \quad \frac{1}{2} (\lambda^\top - \mu^\top) \mathbf{K} \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - (\lambda^\top - \mu^\top) \mathbf{1}_{p+q}$$

subject to

$$\sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j = 0$$

$$0 \leq \lambda_i \leq K, \quad i = 1, \dots, p$$

$$0 \leq \mu_j \leq K, \quad j = 1, \dots, q,$$

where \mathbf{K} is the $\ell \times \ell$ kernel symmetric matrix (with $\ell = p + q$) given at the end of Section 54.1. We also find that

$$w = \sum_{i=1}^p \lambda_i \varphi(u_i) - \sum_{j=1}^q \mu_j \varphi(v_j),$$

so

$$b = \frac{1}{2} \left(\sum_{i=1}^p \lambda_i (\kappa(u_i, u_{i_0}) + \kappa(u_i, v_{j_0})) - \sum_{j=1}^q \mu_j (\kappa(v_j, u_{i_0}) + \kappa(v_j, v_{j_0})) \right),$$

and the classification function

$$f(x) = \text{sgn}(\langle w, \varphi(x) \rangle - b)$$

is given by

$$f(x) = \text{sgn} \left(\sum_{i=1}^p \lambda_i (2\kappa(u_i, x) - \kappa(u_i, u_{i_0}) - \kappa(u_i, v_{j_0})) - \sum_{j=1}^q \mu_j (2\kappa(v_j, x) - \kappa(v_j, u_{i_0}) - \kappa(v_j, v_{j_0})) \right).$$

54.4 Solving SVM (SVM_{s2}) Using ADMM

In order to solve (SVM_{s2}) using ADMM we need to write the matrix corresponding to the constraints in equational form,

$$\begin{aligned} \sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j &= 0 \\ \lambda_i + \alpha_i &= K, \quad i = 1, \dots, p \\ \mu_j + \beta_j &= K, \quad j = 1, \dots, q. \end{aligned}$$

This is the $(p+q+1) \times 2(p+q)$ matrix A given by

$$A = \begin{pmatrix} \mathbf{1}_p^\top & -\mathbf{1}_q^\top & 0_p^\top & 0_q^\top \\ I_p & 0_{p,q} & I_p & 0_{p,q} \\ 0_{q,p} & I_q & 0_{q,p} & I_q \end{pmatrix}.$$

We leave it as an exercise to prove that A has rank $p+q+1$. The right-hand side is

$$c = \begin{pmatrix} 0 \\ K\mathbf{1}_{p+q} \end{pmatrix}.$$

The symmetric positive semidefinite $(p+q) \times (p+q)$ matrix P defining the quadratic functional is

$$P = X^\top X, \quad \text{with} \quad X = \begin{pmatrix} -u_1 & \cdots & -u_p & v_1 & \cdots & v_q \end{pmatrix},$$

and

$$q = -\mathbf{1}_{p+q}.$$

Since there are $2(p+q)$ Lagrange multipliers $(\lambda, \mu, \alpha, \beta)$, the $(p+q) \times (p+q)$ matrix $X^\top X$ must be augmented with zero's to make it a $2(p+q) \times 2(p+q)$ matrix P_a given by

$$P_a = \begin{pmatrix} X^\top X & 0_{p+q,p+q} \\ 0_{p+q,p+q} & 0_{p+q,p+q} \end{pmatrix},$$

and similarly q is augmented with zeros as the vector

$$q_a = \begin{pmatrix} -\mathbf{1}_{p+q} \\ 0_{p+q} \end{pmatrix}$$

54.5 Soft Margin Support Vector Machines; $(\text{SVM}_{s2'})$

In this section we consider a generalization of Problem (SVM_{s2}) for a version of the soft margin SVM coming from Problem (SVM_{h2}) by adding an extra degree of freedom, namely instead of the margin $\delta = 1/\|w\|$, we use the margin $\delta = \eta/\|w\|$ where η is some positive constant that we wish to maximize. To do so, we add a term $-K_m\eta$ to the objective function $(1/2)w^\top w$ as well as the “regularizing term” $K_s \left(\sum_{i=1}^p \epsilon_i + \sum_{j=1}^q \xi_j \right)$ whose purpose is to make ϵ and ξ sparse, where $K_m > 0$ (m refers to margin) and $K_s > 0$ (s refers to sparse) are fixed constants that can be adjusted to determine the influence of η and the regularizing term.

Soft margin SVM ($\text{SVM}_{s2'}$):

$$\begin{aligned} & \text{minimize} \quad \frac{1}{2} w^\top w - K_m \eta + K_s (\epsilon^\top \xi^\top) \mathbf{1}_{p+q} \\ & \text{subject to} \\ & \quad w^\top u_i - b \geq \eta - \epsilon_i, \quad \epsilon_i \geq 0 \quad i = 1, \dots, p \\ & \quad -w^\top v_j + b \geq \eta - \xi_j, \quad \xi_j \geq 0 \quad j = 1, \dots, q \\ & \quad \eta \geq 0. \end{aligned}$$

This version of the SVM problem was first discussed in Schölkopf, Smola, Williamson, and Bartlett [147] under the name of ν -SVC (or ν -SVM), and also used in Schölkopf, Platt, Shawe-Taylor, and Smola [146]. The ν -SVC method is also presented in Schölkopf and Smola [145] (which contains much more). The difference between the ν -SVC method and the method presented in Section 54.3, sometimes called the C -SVM method, was thoroughly investigated by Chan and Lin [36].

For this problem it is no longer clear that if $(w, \eta, b, \epsilon, \xi)$ is an optimal solution, then $w \neq 0$ and $\eta > 0$. In fact, if the sets of points are not linearly separable and if K_s is chosen too big, Problem ($\text{SVM}_{s2'}$) may fail to have an optimal solution.

We show that in order for the problem to have a solution we must pick K_m and K_s so that

$$K_m \leq \min\{2pK_s, 2qK_s\}.$$

If we define ν by

$$\nu = \frac{K_m}{(p+q)K_s},$$

then $K_m \leq \min\{2pK_s, 2qK_s\}$ is equivalent to

$$\nu \leq \min\left\{\frac{2p}{p+q}, \frac{2q}{p+q}\right\} \leq 1.$$

The reason for introducing ν is that $\nu(p+q)/2$ can be interpreted as the maximum number of points failing to achieve the margin $\delta = \eta/\|w\|$. We will show later that if the points u_i and v_j are not separable, then we must pick ν so that $\nu \geq 2/(p+q)$ for the method to have a solution for which $w \neq 0$ and $\eta > 0$.

The objective function of our problem is convex and the constraints are affine. Consequently, by Theorem 50.17(2) if the Primal Problem ($\text{SVM}_{s2'}$) has an optimal solution, then the dual problem has a solution too, and the duality gap is zero. This does not immediately imply that an optimal solution of the dual yields an optimal solution of the primal because the hypotheses of Theorem 50.17(1) fail to hold.

We show that if the primal problem has an optimal solution $(w, \eta, \epsilon, \xi, b)$ with $w \neq 0$, then any optimal solution of the dual problem determines λ and μ , which in turn determine

w via the equation

$$w = -X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = \sum_{i=1}^p \lambda_i u_i - \sum_{j=1}^q \mu_j v_j, \quad (*_w)$$

and $\eta \geq 0$.

It remains to determine b, η, ϵ and ξ . The solution of the dual does not determine b, η, ϵ, ξ directly, and we are not aware of necessary and sufficient conditions that ensure that they can be determined. The best we can do is to use the KKT conditions.

The simplest sufficient condition is what we call the

Standard Margin Hypothesis for (SVM_{s2'}): There is some i_0 such that $0 < \lambda_{i_0} < K_s$, and there is some μ_{j_0} such that $0 < \mu_{j_0} < K_s$. This means that there is some support vector u_{i_0} of type 1 and there is some support vector v_{j_0} of type 1.

In this case, then by complementary slackness, it can be shown that $\epsilon_{i_0} = 0, \xi_{i_0} = 0$, and the corresponding inequalities are active, that is we have the equations

$$w^\top u_{i_0} - b = \eta, \quad -w^\top v_{j_0} + b = \eta,$$

so we can solve for b and η . Then since by complementary slackness, if $\epsilon_i > 0$, then $\lambda_i = K_s$ and if $\xi_j > 0$, then $\mu_j = K_s$, all inequalities corresponding to such $\epsilon_i > 0$ and $\mu_j > 0$ are active, and we can solve for ϵ_i and ξ_j .

The linear constraints are given by the $(2(p+q)+1) \times (n+p+q+2)$ matrix given in block form by

$$C = \begin{pmatrix} X^\top & -I_{p+q} & \mathbf{1}_p & \mathbf{1}_{p+q} \\ 0_{p+q,n} & -I_{p+q} & 0_{p+q} & 0_{p+q} \\ 0_n^\top & 0_{p+q}^\top & 0 & -1 \end{pmatrix},$$

where X is the $n \times (p+q)$ matrix

$$X = (-u_1 \ \cdots \ -u_p \ v_1 \ \cdots \ v_q),$$

and the linear constraints are expressed by

$$\begin{pmatrix} X^\top & -I_{p+q} & \mathbf{1}_p & \mathbf{1}_{p+q} \\ 0_{p+q,n} & -I_{p+q} & 0_{p+q} & 0_{p+q} \\ 0_n^\top & 0_{p+q}^\top & 0 & -1 \end{pmatrix} \begin{pmatrix} w \\ \epsilon \\ \xi \\ b \\ \eta \end{pmatrix} \leq \begin{pmatrix} 0_{p+q} \\ 0_{p+q} \\ 0 \end{pmatrix}.$$

The objective function is given by

$$J(w, \epsilon, \xi, b, \eta) = \frac{1}{2} w^\top w - K_m \eta + K_s (\epsilon^\top \ \xi^\top) \mathbf{1}_{p+q}.$$

The Lagrangian $L(w, \epsilon, \xi, b, \eta, \lambda, \mu, \alpha, \beta, \gamma)$ with $\lambda, \alpha \in \mathbb{R}_+^p$, $\mu, \beta \in \mathbb{R}_+^q$, and $\gamma \in \mathbb{R}_+$ is given by

$$\begin{aligned} L(w, \epsilon, \xi, b, \eta, \lambda, \mu, \alpha, \beta, \gamma) &= \frac{1}{2} w^\top w - K_m \eta + K_s (\epsilon^\top \xi^\top) \mathbf{1}_{p+q} \\ &\quad + (w^\top (\epsilon^\top \xi^\top) b \eta) C^\top \begin{pmatrix} \lambda \\ \mu \\ \alpha \\ \beta \\ \gamma \end{pmatrix}. \end{aligned}$$

Since

$$\begin{aligned} (w^\top (\epsilon^\top \xi^\top) b \eta) C^\top \begin{pmatrix} \lambda \\ \mu \\ \alpha \\ \beta \\ \gamma \end{pmatrix} &= w^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - \epsilon^\top (\lambda + \alpha) - \xi^\top (\mu + \beta) + b(\mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu) \\ &\quad + \eta(\mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu) - \gamma \eta, \end{aligned}$$

the Lagrangian can be written as

$$\begin{aligned} L(w, \epsilon, \xi, b, \eta, \lambda, \mu, \alpha, \beta, \gamma) &= \frac{1}{2} w^\top w - K_m \eta + K_s (\epsilon^\top \mathbf{1}_p + \xi^\top \mathbf{1}_q) + w^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - \epsilon^\top (\lambda + \alpha) \\ &\quad - \xi^\top (\mu + \beta) + b(\mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu) + \eta(\mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu) - \gamma \eta \\ &= \frac{1}{2} w^\top w + w^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + (\mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu - K_m - \gamma) \eta \\ &\quad + \epsilon^\top (K_s \mathbf{1}_p - (\lambda + \alpha)) + \xi^\top (K_s \mathbf{1}_q - (\mu + \beta)) + b(\mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu). \end{aligned}$$

To find the dual function $G(\lambda, \mu, \alpha, \beta, \gamma)$ we minimize $L(w, \epsilon, \xi, b, \eta, \lambda, \mu, \alpha, \beta, \gamma)$ with respect to w, ϵ, ξ, b , and η . Since the Lagrangian is convex and $(w, \epsilon, \xi, b, \eta) \in \mathbb{R}^n \times \mathbb{R}^p \times \mathbb{R}^q \times \mathbb{R} \times \mathbb{R}$, a convex open set, by Theorem 40.13, the Lagrangian has a minimum in $(w, \epsilon, \xi, b, \eta)$ iff $\nabla L_{w, \epsilon, \xi, b, \eta} = 0$, so we compute its gradient with respect to $w, \epsilon, \xi, b, \eta$, and we get

$$\nabla L_{w, \epsilon, \xi, b, \eta} = \begin{pmatrix} X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + w \\ K_s \mathbf{1}_p - (\lambda + \alpha) \\ K_s \mathbf{1}_q - (\mu + \beta) \\ \mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu \\ \mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu - K_m - \gamma \end{pmatrix}.$$

By setting $\nabla L_{w, \epsilon, \xi, b, \eta} = 0$ we get the equations

$$w = -X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \tag{*_w}$$

$$\begin{aligned}\lambda + \alpha &= K_s \mathbf{1}_p \\ \mu + \beta &= K_s \mathbf{1}_q \\ \mathbf{1}_p^\top \lambda &= \mathbf{1}_q^\top \mu,\end{aligned}$$

and

$$\mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu = K_m + \gamma. \quad (*_\gamma)$$

The second and third equations are equivalent to the box constraints

$$0 \leq \lambda_i, \mu_j \leq K_s, \quad i = 1, \dots, p, j = 1, \dots, q,$$

and since $\gamma \geq 0$ equation $(*_\gamma)$ is equivalent to

$$\mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu \geq K_m.$$

Plugging back w from $(*_w)$ into the Lagrangian, after simplifications we get

$$\begin{aligned}G(\lambda, \mu, \alpha, \beta) &= \frac{1}{2} (\lambda^\top - \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - (\lambda^\top - \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ &= -\frac{1}{2} (\lambda^\top - \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix},\end{aligned}$$

so the dual function is independent of α, β and is given by

$$G(\lambda, \mu) = -\frac{1}{2} (\lambda^\top - \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix}.$$

The dual program is given by

$$\begin{aligned}&\text{maximize} \quad -\frac{1}{2} (\lambda^\top - \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ &\text{subject to} \\ &\sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j = 0 \\ &\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j \geq K_m \\ &0 \leq \lambda_i \leq K_s, \quad i = 1, \dots, p \\ &0 \leq \mu_j \leq K_s, \quad j = 1, \dots, q.\end{aligned}$$

Finally, the dual program is equivalent to the following minimization program:

Dual of Soft margin SVM ($\text{SVM}_{s2'}$):

$$\text{minimize} \quad \frac{1}{2} (\lambda^\top - \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix}$$

subject to

$$\sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j = 0$$

$$\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j \geq K_m$$

$$0 \leq \lambda_i \leq K_s, \quad i = 1, \dots, p$$

$$0 \leq \mu_j \leq K_s, \quad j = 1, \dots, q.$$

If $(w, \eta, \epsilon, \xi, b)$ is an optimal solution of Problem ($\text{SVM}_{s2'}$) with $w \neq 0$ and $\eta \neq 0$, then the complementary slackness conditions yield a classification of the points u_i and v_j in terms of the values of λ and μ . Indeed, we have $\epsilon_i \alpha_i = 0$ for $i = 1, \dots, p$ and $\xi_j \beta_j = 0$ for $j = 1, \dots, q$. Also, if $\lambda_i > 0$, then the corresponding constraint is active, and similarly if $\mu_j > 0$. Since $\lambda_i + \alpha_i = K_s$, it follows that $\epsilon_i \alpha_i = 0$ iff $\epsilon_i (K_s - \lambda_i) = 0$, and since $\mu_j + \beta_j = K_s$, we have $\xi_j \beta_j = 0$ iff $\xi_j (K_s - \mu_j) = 0$. Thus if $\epsilon_i > 0$, then $\lambda_i = K_s$, and if $\xi_j > 0$, then $\mu_j = K_s$. Consequently, if $\lambda_i < K_s$, then $\epsilon_i = 0$ and u_i is correctly classified, and similarly if $\mu_j < K_s$, then $\xi_j = 0$ and v_j is correctly classified.

We have the following classification which is basically the classification given in Section 54.1 obtained by replacing δ with η (recall that $\eta > 0$ and $\delta = \eta / \|w\|$).

- (1) If $0 < \lambda_i < K_s$, then $\epsilon_i = 0$ and the i -th inequality is active, so

$$w^\top u_i - b - \eta = 0.$$

This means that u_i is on the blue margin (the hyperplane $H_{w,b+\eta}$ of equation $w^\top x = b + \eta$) and is classified correctly.

Similarly, if $0 < \mu_j < K_s$, then $\xi_j = 0$ and

$$w^\top v_j - b + \eta = 0,$$

so v_j is on the red margin (the hyperplane $H_{w,b-\eta}$ of equation $w^\top x = b - \eta$) and is classified correctly.

- (2) If $\lambda_i = K_s$, then the i -th inequality is active, so

$$w^\top u_i - b - \eta = -\epsilon_i.$$

If $\epsilon_i = 0$, then the point u_i is on the blue margin. If $\epsilon_i > 0$, then u_i is within the open half space bounded by the blue margin hyperplane $H_{w,b+\eta}$ and containing the

separating hyperplane $H_{w,b}$; if $\epsilon_i \leq \eta$, then u_i is classified correctly, and if $\epsilon_i > \eta$, then u_i is misclassified (u_i lies on the wrong side of the separating hyperplane, the red side).

Similarly, if $\mu_j = K_s$, then

$$w^\top v_j - b + \eta = \xi_j.$$

If $\xi_j = 0$, then the point v_j is on the red margin. If $\xi_j > 0$, then v_j is within the open half space bounded by the red margin hyperplane $H_{w,b-\eta}$ and containing the separating hyperplane $H_{w,b}$; if $\xi_j \leq \eta$, then v_j is classified correctly, and if $\xi_j > \eta$, then v_j is misclassified (v_j lies on the wrong side of the separating hyperplane, the blue side).

- (3) If $\lambda_i = 0$, then $\epsilon_i = 0$ and the i -th inequality may or may not be active, so

$$w^\top u_i - b - \eta \geq 0.$$

Thus u_i is in the closed half space on the blue side bounded by the blue margin hyperplane $H_{w,b+\eta}$ (of course, classified correctly).

Similarly, if $\mu_j = 0$, then

$$w^\top v_j - b + \eta \leq 0$$

and v_j is in the closed half space on the red side bounded by the red margin hyperplane $H_{w,b-\eta}$ (of course, classified correctly).

Definition 54.2. The vectors u_i on the blue margin $H_{w,b+\eta}$ and the vectors v_j on the red margin $H_{w,b-\eta}$ are called *support vectors*. Support vectors correspond to vectors u_i for which $w^\top u_i - b - \eta = 0$ (which implies $\epsilon_i = 0$), and vectors v_j for which $w^\top v_j - b + \eta = 0$ (which implies $\xi_j = 0$). Support vectors u_i such that $0 < \lambda_i < K_s$ and support vectors v_j such that $0 < \mu_j < K_s$ are *support vectors of type 1*. Support vectors of type 1 play a special role so we denote the sets of indices associated with them by

$$\begin{aligned} I_\lambda &= \{i \in \{1, \dots, p\} \mid 0 < \lambda_i < K_s\} \\ I_\mu &= \{j \in \{1, \dots, q\} \mid 0 < \mu_j < K_s\}. \end{aligned}$$

We denote their cardinalities by $numsvl_1 = |I_\lambda|$ and $numsvm_1 = |I_\mu|$. Support vectors u_i such that $\lambda_i = K_s$ and support vectors v_j such that $\mu_j = K_s$ are *support vectors of type 2*. Those support vectors u_i such that $\lambda_i = 0$ and those support vectors v_j such that $\mu_j = 0$ are called *exceptional support vectors*.

The vectors u_i for which $\lambda_i = K_s$ and the vectors v_j for which $\mu_j = K_s$ are said to *fail the margin*. The sets of indices associated with the vectors failing the margin are denoted by

$$\begin{aligned} K_\lambda &= \{i \in \{1, \dots, p\} \mid \lambda_i = K_s\} \\ K_\mu &= \{j \in \{1, \dots, q\} \mid \mu_j = K_s\}. \end{aligned}$$

We denote their cardinalities by $p_f = |K_\lambda|$ and $q_f = |K_\mu|$.

It will also be useful to understand how points are classified in terms of ϵ_i (or ξ_j).

- (1) If $\epsilon_i > 0$, then by complementary slackness $\lambda_i = K_s$, so the i th equation is active and by (2) above,

$$w^\top u_i - b - \eta = -\epsilon_i.$$

Since $\epsilon_i > 0$, the point u_i is strictly within the open half space bounded by the blue margin hyperplane $H_{w,b+\eta}$ and containing the separating hyperplane $H_{w,b}$ (excluding the blue hyperplane $H_{w,b+\eta}$); if $\epsilon_i \leq \eta$, then u_i is classified correctly, and if $\epsilon_i > \eta$, then u_i is misclassified.

Similarly, if $\xi_j > 0$, then v_j is strictly within the open half space bounded by the red margin hyperplane $H_{w,b-\eta}$ and containing the separating hyperplane $H_{w,b}$ (excluding the red hyperplane $H_{w,b-\eta}$); if $\xi_j \leq \eta$, then v_j is classified correctly, and if $\xi_j > \eta$, then v_j is misclassified.

- (2) If $\epsilon_i = 0$, then the point u_i is correctly classified. If $\lambda_i = 0$, then by (3) above, u_i is in the closed half space on the blue side bounded by the blue margin hyperplane $H_{w,b+\eta}$. If $\lambda_i > 0$, then by (1) and (2) above, the point u_i is on the blue margin.

Similarly, if $\xi_j = 0$, then the point v_j is correctly classified. If $\mu_j = 0$, then v_j is in the closed half space on the red side bounded by the red margin hyperplane $H_{w,b-\eta}$, and if $\mu_j > 0$, then the point v_j is on the red margin.

Also observe that if $\lambda_i > 0$, then u_i is in the closed half space bounded by the blue hyperplane $H_{w,b+\eta}$ and containing the separating hyperplane $H_{w,b}$ (including the blue hyperplane $H_{w,b+\eta}$).

Similarly, if $\mu_j > 0$, then v_j is in the closed half space bounded by the red hyperplane $H_{w,b-\eta}$ and containing the separating hyperplane $H_{w,b}$ (including the red hyperplane $H_{w,b-\eta}$).

Definition 54.3. Vectors u_i such that $\lambda_i > 0$ and vectors v_j such that $\mu_j > 0$ are said to have *margin at most* δ . The sets of indices associated with these vectors are denoted by

$$\begin{aligned} I_{\lambda>0} &= \{i \in \{1, \dots, p\} \mid \lambda_i > 0\} \\ I_{\mu>0} &= \{j \in \{1, \dots, q\} \mid \mu_j > 0\}. \end{aligned}$$

We denote their cardinalities by $p_m = |I_{\lambda>0}|$ and $q_m = |I_{\mu>0}|$.

Vectors u_i such that $\epsilon_i > 0$ and vectors v_j such that $\xi_j > 0$ are said to *strictly fail the margin*. The corresponding sets of indices are denoted by

$$\begin{aligned} E_\lambda &= \{i \in \{1, \dots, p\} \mid \epsilon_i > 0\} \\ E_\mu &= \{j \in \{1, \dots, q\} \mid \xi_j > 0\}. \end{aligned}$$

We write $p_{sf} = |E_\lambda|$ and $q_{sf} = |E_\mu|$.

We have the inclusions $E_\lambda \subseteq K_\lambda$ and $E_\mu \subseteq K_\mu$. The difference between the first sets and the second sets is that the second sets may contain support vectors such that $\lambda_i = K_s$ and $\epsilon_i = 0$, or $\mu_j = K_s$ and $\xi_j = 0$. We also have the equations $I_\lambda \cup K_\lambda = I_{\lambda > 0}$ and $I_\mu \cup K_\mu = I_{\mu > 0}$, and the inequalities $p_{sf} \leq p_f \leq p_m$ and $q_{sf} \leq q_f \leq q_m$.

It is shown in Section 54.8 how the dual program is solved using ADMM from Section 52.6. If the primal problem is solvable, this yields solutions for λ and μ . Once a solution for λ and μ is obtained, we have

$$w = -X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = \sum_{i=1}^p \lambda_i u_i - \sum_{j=1}^q \mu_j v_j.$$

As we said earlier, the hypotheses of Theorem 50.17(2) hold, so *if* the primal problem ($\text{SVM}_{s2'}$) has an optimal solution with $w \neq 0$, *then* the dual problem has a solution too, and the duality gap is zero. Therefore, for optimal solutions we have

$$L(w, \epsilon, \xi, b, \eta, \lambda, \mu, \alpha, \beta, \gamma) = G(\lambda, \mu, \alpha, \beta, \gamma),$$

which means that

$$\frac{1}{2} w^\top w - K_m \eta + K_s \left(\sum_{i=1}^p \epsilon_i + \sum_{j=1}^q \xi_j \right) = -\frac{1}{2} (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix},$$

and since

$$w = -X \begin{pmatrix} \lambda \\ \mu \end{pmatrix},$$

we get

$$\frac{1}{2} (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - K_m \eta + K_s \left(\sum_{i=1}^p \epsilon_i + \sum_{j=1}^q \xi_j \right) = -\frac{1}{2} (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix},$$

which yields

$$\eta = \frac{K_s}{K_m} \left(\sum_{i=1}^p \epsilon_i + \sum_{j=1}^q \xi_j \right) + \frac{1}{K_m} (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix}. \quad (*)$$

Therefore, we confirm that $\eta \geq 0$.

Remarks: Since we proved that if the Primal Problem ($\text{SVM}_{s2'}$) has an optimal solution with $w \neq 0$, then $\eta \geq 0$, one might wonder why the constraint $\eta \geq 0$ was included. If we delete this constraint, it is easy to see that the only difference is that instead of the equation

$$\mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu = K_m + \gamma \quad (*_1)$$

we obtain the equation

$$\mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu = K_m. \quad (*_2)$$

If $\eta > 0$, then by complementary slackness $\gamma = 0$, in which case $(*_1)$ and $(*_2)$ are equivalent. But if $\eta = 0$, then γ could be strictly positive.

The option to omit the constraint $\eta \geq 0$ in the primal is slightly advantageous because then the dual involves $2(p+q)$ instead of $2(p+q)+1$ Lagrange multipliers, so the constraint matrix is a $(p+q+2) \times 2(p+q)$ matrix instead of a $(p+q+2) \times (2(p+q)+1)$ matrix and the matrix defining the quadratic functional is a $2(p+q) \times 2(p+q)$ matrix instead of a $(2(p+q)+1) \times (2(p+q)+1)$ matrix; see Section 54.8.

Under the **Standard Margin Hypothesis** for ($\text{SVM}_{s2'}$), there is some i_0 such that $0 < \lambda_{i_0} < K_s$ and some j_0 such that $0 < \mu_{j_0} < K_s$, and by the complementary slackness conditions $\epsilon_{i_0} = 0$ and $\xi_{j_0} = 0$, so we have the two active constraints

$$w^\top u_{i_0} - b = \eta, \quad -w^\top v_{j_0} + b = \eta,$$

and we can solve for b and η and we get

$$\begin{aligned} b &= \frac{w^\top u_{i_0} + w^\top v_{j_0}}{2} \\ \eta &= \frac{w^\top u_{i_0} - w^\top v_{j_0}}{2} \\ \delta &= \frac{\eta}{\|w\|}. \end{aligned}$$

Due to numerical instability, when writing a computer program it is preferable to compute the lists of indices I_λ and I_μ given by

$$\begin{aligned} I_\lambda &= \{i \in \{1, \dots, p\} \mid 0 < \lambda_i < K_s\} \\ I_\mu &= \{j \in \{1, \dots, q\} \mid 0 < \mu_j < K_s\}. \end{aligned}$$

Then it is easy to see that we can compute b and η using the following averaging formulae:

$$\begin{aligned} b &= w^\top \left(\left(\sum_{i \in I_\lambda} u_i \right) / |I_\lambda| + \left(\sum_{j \in I_\mu} v_j \right) / |I_\mu| \right) / 2 \\ \eta &= w^\top \left(\left(\sum_{i \in I_\lambda} u_i \right) / |I_\lambda| - \left(\sum_{j \in I_\mu} v_j \right) / |I_\mu| \right) / 2. \end{aligned}$$

The “kernelized” version of Problem ($\text{SVM}_{s2'}$) is the following:

Soft margin kernel SVM ($\text{SVM}_{s2'}$):

$$\text{minimize} \quad \frac{1}{2} \langle w, w \rangle - K_m \eta + K_s (\epsilon^\top \xi^\top) \mathbf{1}_{p+q}$$

subject to

$$\begin{aligned} \langle w, \varphi(u_i) \rangle - b &\geq \eta - \epsilon_i, \quad \epsilon_i \geq 0 \quad i = 1, \dots, p \\ -\langle w, \varphi(v_j) \rangle + b &\geq \eta - \xi_j, \quad \xi_j \geq 0 \quad j = 1, \dots, q \\ \eta &\geq 0. \end{aligned}$$

Tracing through the derivation of the dual program we obtain

Dual of the Soft margin kernel SVM (SVM_{s2'}):

$$\text{minimize} \quad \frac{1}{2} (\lambda^\top - \mu^\top) \mathbf{K} \begin{pmatrix} \lambda \\ \mu \end{pmatrix}$$

subject to

$$\sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j = 0$$

$$\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j \geq K_m$$

$$0 \leq \lambda_i \leq K_s, \quad i = 1, \dots, p$$

$$0 \leq \mu_j \leq K_s, \quad j = 1, \dots, q,$$

where \mathbf{K} is the kernel matrix of Section 54.1.

As in Section 54.3, we obtain

$$w = \sum_{i=1}^p \lambda_i \varphi(u_i) - \sum_{j=1}^q \mu_j \varphi(v_j),$$

so

$$b = \frac{1}{2} \left(\sum_{i=1}^p \lambda_i (\kappa(u_i, u_{i_0}) + \kappa(u_i, v_{j_0})) - \sum_{j=1}^q \mu_j (\kappa(v_j, u_{i_0}) + \kappa(v_j, v_{j_0})) \right),$$

and the classification function

$$f(x) = \text{sgn}(\langle w, \varphi(x) \rangle - b)$$

is given by

$$\begin{aligned} f(x) = & \text{sgn} \left(\sum_{i=1}^p \lambda_i (2\kappa(u_i, x) - \kappa(u_i, u_{i_0}) - \kappa(u_i, v_{j_0})) \right. \\ & \left. - \sum_{j=1}^q \mu_j (2\kappa(v_j, x) - \kappa(v_j, u_{i_0}) - \kappa(v_j, v_{j_0})) \right). \end{aligned}$$

54.6 Classification of the Data Points in Terms of ν (SVM_{s2'})

For a finer classification of the points it turns out to be convenient to consider the ratio

$$\nu = \frac{K_m}{(p+q)K_s}.$$

First note that in order for the constraints to be satisfied, some relationship between K_s and K_m must hold. In addition to the constraints

$$0 \leq \lambda_i \leq K_s, \quad 0 \leq \mu_j \leq K_s,$$

we also have the constraints

$$\begin{aligned} \sum_{i=1}^p \lambda_i &= \sum_{j=1}^q \mu_j \\ \sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j &\geq K_m \end{aligned}$$

which imply that

$$\sum_{i=1}^p \lambda_i \geq \frac{K_m}{2} \quad \text{and} \quad \sum_{j=1}^q \mu_j \geq \frac{K_m}{2}. \quad (\dagger)$$

Since λ, μ are all nonnegative, if $\lambda_i = K_s$ for all i and if $\mu_j = K_s$ for all j , then

$$\frac{K_m}{2} \leq \sum_{i=1}^p \lambda_i \leq pK_s \quad \text{and} \quad \frac{K_m}{2} \leq \sum_{j=1}^q \mu_j \leq qK_s,$$

so these constraints are not satisfied unless $K_m \leq \min\{2pK_s, 2qK_s\}$, so we assume that $K_m \leq \min\{2pK_s, 2qK_s\}$. The equations in (\dagger) also imply that there is some i_0 such that $\lambda_{i_0} > 0$ and some j_0 such that $\mu_{j_0} > 0$, and so $p_m \geq 1$ and $q_m \geq 1$.

For a finer classification of the points we find it convenient to define $\nu > 0$ such that

$$\nu = \frac{K_m}{(p+q)K_s},$$

so that the objective function $J(w, \epsilon, \xi, b, \eta)$ is given by

$$J(w, \epsilon, \xi, b, \eta) = \frac{1}{2} w^\top w + (p+q)K_s \left(-\nu\eta + \frac{1}{p+q} (\epsilon^\top \quad \xi^\top) \mathbf{1}_{p+q} \right).$$

Observe that the condition $K_m \leq \min\{2pK_s, 2qK_s\}$ is equivalent to

$$\nu \leq \min \left\{ \frac{2p}{p+q}, \frac{2q}{p+q} \right\} \leq 1.$$

Since we obtain an equivalent problem by rescaling by a common positive factor, theoretically it is convenient to normalize K_s as

$$K_s = \frac{1}{p+q},$$

in which case $K_m = \nu$. This method is called the ν -support vector machine. Actually, to program the method, it may be more convenient assume that K_s is arbitrary. This helps in avoiding λ_i and μ_j to become too small when $p + q$ is relatively large.

The equations (\dagger) and the box inequalities

$$0 \leq \lambda_i \leq K_s, \quad 0 \leq \mu_j \leq K_s$$

also imply the following facts:

Proposition 54.1. *If Problem (SVM_{s2'}) has an optimal solution with $w \neq 0$ and $\eta > 0$, then the following facts hold:*

- (1) *Let p_f be the number of points u_i such that $\lambda_i = K_s$, and let q_f the number of points v_j such that $\mu_j = K_s$. Then $p_f, q_f \leq \nu(p + q)/2$.*
- (2) *Let p_m be the number of points u_i such that $\lambda_i > 0$, and let q_m the number of points v_j such that $\mu_j > 0$. Then $p_m, q_m \geq \nu(p + q)/2$. We have $p_m \geq 1$ and $q_m \geq 1$.*
- (3) *If $p_f \geq 1$ or $q_f \geq 1$, then $\nu \geq 2/(p + q)$.*

Proof. (1) Recall that for an optimal solution with $w \neq 0$ and $\eta > 0$, we have $\gamma = 0$, so by $(*_\gamma)$ we have the equations

$$\sum_{i=1}^p \lambda_i = \frac{K_m}{2} \quad \text{and} \quad \sum_{j=1}^q \mu_j = \frac{K_m}{2}.$$

The point u_i fails to achieve the margin iff $\lambda_i = K_s = K_m/(\nu(p + q))$, so if there are p_f such points then

$$\frac{K_m}{2} = \sum_{i=1}^p \lambda_i \geq \frac{K_m p_f}{\nu(p + q)},$$

so

$$p_f \leq \frac{\nu(p + q)}{2}.$$

A similar reasoning applies if v_j fails to achieve the margin δ with $\sum_{i=1}^p \lambda_i$ replaced by $\sum_{j=1}^q \mu_j$.

- (2) A point u_i has margin at most δ iff $\lambda_i > 0$. If

$$I_{\lambda>0} = \{i \in \{1, \dots, p\} \mid \lambda_i > 0\} \quad \text{and} \quad p_m = |I_{\lambda>0}|,$$

then

$$\frac{K_m}{2} = \sum_{i=1}^p \lambda_i = \sum_{i \in I_{\lambda>0}} \lambda_i,$$

and since $\lambda_i \leq K_s = K_m/(\nu(p+q))$, we have

$$\frac{K_m}{2} = \sum_{i \in I_{\lambda > 0}} \lambda_i \leq \frac{K_m p_m}{\nu(p+q)},$$

which yields

$$p_m \geq \frac{\nu(p+q)}{2}.$$

A similar reasoning applies if a point v_j has margin at most δ . We already observed that (†) implies that $p_m \geq 1$ and $q_m \geq 1$.

(3) This follows immediately from (1). \square

Observe that $p_f = q_f = 0$ means that there are no points in the open slab containing the separating hyperplane, namely, the points u_i and the points v_j are separable. So if the points u_i and the points v_j are not separable, then we must pick ν such that $2/(p+q) \leq \nu \leq \min\{2p/(p+q), 2q/(p+q)\}$ for the method to succeed. Otherwise, the method is trying to produce a solution where $w = 0$ and $\eta = 0$, and it does not converge (γ is nonzero). Actually, Proposition 54.1 yields more accurate bounds on ν for the method to converge, namely

$$\max \left\{ \frac{2p_f}{p+q}, \frac{2q_f}{p+q} \right\} \leq \nu \leq \min \left\{ \frac{2p_m}{p+q}, \frac{2q_m}{p+q} \right\}.$$

By a previous remark, $p_f \leq p_m$ and $q_f \leq q_m$, the first inequality being strict if there is some i such that $0 < \lambda_i < K$, and the second inequality being strict if there is some j such that $0 < \mu_j < K$. This will be the case under the **Standard Margin Hypothesis**.

Observe that a small value of ν keeps p_f and q_f small, which is achieved if the δ -slab is narrow (to avoid having points on the wrong sides of the margin hyperplanes). A large value of ν allows p_m and q_m to be fairly large, which is achieved if the δ -slab is wide. **Thus the smaller ν is, the narrower the δ -slab is, and the larger ν is, the wider the δ -slab is.** This is the opposite of the behavior that we witnessed in ν -regression (see Section 56.1).

54.7 Existence of Support Vectors for (SVM_{s2'})

We now consider the issue of the existence of support vectors. We will show that in the “generic case” there is always some blue support vector and some red support vector. The term generic has to do with the choice of ν and will be explained below.

Given any real numbers u, v, x, y , if $\max\{u, v\} < \min\{x, y\}$, then $u < x$ and $v < y$. This is because $u, v \leq \max\{u, v\} < \min\{x, y\} \leq x, y$. Consequently, since by Proposition 54.1, $\max\{2p_f/(p+q), 2q_f/(p+q)\} \leq \nu$, if $\nu < \min\{2p/(p+q), 2q/(p+q)\}$, then $p_f < p$ and $q_f < q$, and since $p_{sf} \leq p_f$ and $q_{sf} \leq q_f$, we also have $p_{sf} < p$ and $q_{sf} < q$. This implies

that there are constraints corresponding to some $i \notin E_\lambda$ (in which case $\epsilon_i = 0$) and to some $j \notin E_\mu$ (in which case $\xi_j = 0$), of the form

$$\begin{array}{ll} w^\top u_i - b \geq \eta & i \notin E_\lambda \\ -w^\top v_j + b \geq \eta & j \notin E_\mu. \end{array}$$

If $w^\top u_i - b = \eta$ for some $i \notin E_\lambda$ and $-w^\top v_j + b = \eta$ for some $j \notin E_\mu$, then we have a blue support vector and a red support vector. Otherwise, we show how to modify b and η to obtain an optimal solution with a blue support vector and a red support vector.

Proposition 54.2. *For every optimal solution $(w, b, \eta, \epsilon, \xi)$ of Problem (SVM_{s2'}) with $w \neq 0$ and $\eta > 0$, if*

$$\nu < \min\{2p/(p+q), 2q/(p+q)\}$$

and if either no u_i is a support vector or no v_j is a support vector, then there is another optimal solution (for the same w) with some i_0 such that $\epsilon_{i_0} = 0$ and $w^\top u_{i_0} - b = \eta$, and there is some j_0 such that $\xi_{j_0} = 0$ and $-w^\top v_{j_0} + b = \eta$; in other words, some u_{i_0} and some v_{j_0} is a support vector; in particular, $p_{sf} < p$ and $q_{sf} < q$.

Proof. We just explained that $p_{sf} < p$ and $q_{sf} < q$, so the following constraints hold:

$$\begin{array}{lll} w^\top u_i - b = \eta - \epsilon_i & \epsilon_i > 0 & i \in E_\lambda \\ -w^\top v_j + b = \eta - \xi_j & \xi_j > 0 & j \in E_\mu \\ w^\top u_i - b \geq \eta & & i \notin E_\lambda \\ -w^\top v_j + b \geq \eta & & j \notin E_\mu, \end{array}$$

where there is some $i \notin E_\lambda$ and some $j \notin E_\mu$.

If our optimal solution does not have a blue support vector and a red support vector, then either $w^\top u_i - b > \eta$ for all $i \notin E_\lambda$ or $-w^\top v_j + b > \eta$ for all $j \notin E_\mu$.

Case 1. We have

$$\begin{array}{ll} w^\top u_i - b > \eta & i \notin E_\lambda \\ -w^\top v_j + b \geq \eta & j \notin E_\mu. \end{array}$$

There are two subcases.

Case 1a. Assume that there is some $j \notin E_\mu$ such that $-w^\top v_j + b = \eta$. Our strategy is to increase η and b by a small amount θ in such a way that some inequality becomes an equation for some $i \notin E_\lambda$. Geometrically, this amounts to raising the separating hyperplane $H_{w,b}$ and increasing the width of the slab, keeping the red margin hyperplane unchanged. See Figure 54.7.

Let us pick θ such that

$$\theta = (1/2) \min\{w^\top u_i - b - \eta \mid i \notin E_\lambda\}.$$

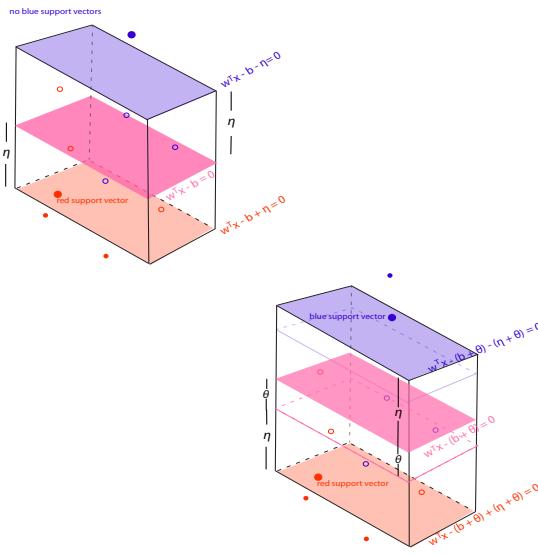

Figure 54.7: In this illustration points with errors are denoted by open circles. In the original, upper left configuration, there is no blue support vector. By raising the pink separating hyperplane and increasing the margin, we end up with a blue support vector.

Our hypotheses imply that $\theta > 0$. We can write

$$\begin{aligned} w^\top u_i - (b + \theta) &= \eta + \theta - (\epsilon_i + 2\theta) & \epsilon_i > 0 & i \in E_\lambda \\ -w^\top v_j + b + \theta &= \eta + \theta - \xi_j & \xi_j > 0 & j \in E_\mu \\ w^\top u_i - (b + \theta) &\geq \eta + \theta & i \notin E_\lambda \\ -w^\top v_j + b + \theta &\geq \eta + \theta & j \notin E_\mu. \end{aligned}$$

By hypothesis

$$-w^\top v_j + b + \theta = \eta + \theta \quad \text{for some } j \notin E_\mu,$$

and by the choice of θ ,

$$w^\top u_i - (b + \theta) = \eta + \theta \quad \text{for some } i \notin E_\lambda.$$

The new value of the objective function is

$$\begin{aligned} \omega(\theta) &= \frac{1}{2} w^\top w - \nu(\eta + \theta) + \frac{1}{p+q} \left(\sum_{i \in E_\lambda} (\epsilon_i + 2\theta) + \sum_{j \in E_\mu} \xi_j \right) \\ &= \frac{1}{2} w^\top w - \nu\eta + \frac{1}{p+q} \left(\sum_{i \in E_\lambda} \epsilon_i + \sum_{j \in E_\mu} \xi_j \right) - \left(\nu - \frac{2p_{sf}}{p+q} \right) \theta. \end{aligned}$$

By Proposition 54.1 we have

$$\max \left\{ \frac{2p_f}{p+q}, \frac{2q_f}{p+q} \right\} \leq \nu$$

and $p_{sf} \leq p_f$ and $q_{sf} \leq q_f$, which implies that

$$\nu - \frac{2p_{sf}}{p+q} \geq 0, \quad (*_1)$$

and so $\omega(\theta) \leq \omega(0)$. If inequality $(*_1)$ is strict, then this contradicts the optimality of the original solution. Therefore, $\nu = 2p_{sf}/(p+q)$, $\omega(\theta) = \omega(0)$, and $(w, b+\theta, \eta+\theta, \epsilon+2\theta, \xi)$ is an optimal solution such that

$$\begin{aligned} w^\top u_i - (b + \theta) &= \eta + \theta \\ -w^\top v_j + b + \theta &= \eta + \theta \end{aligned}$$

for some $i \notin E_\lambda$ and some $j \notin E_\mu$.

Case 1b. We have $-w^\top v_j + b > \eta$ for all $j \notin E_\mu$. Our strategy is to increase η and the errors by a small θ in such a way that some inequality becomes an equation for some $i \notin E_\lambda$ or for some $j \notin E_\mu$. Geometrically, this corresponds to increasing the width of the slab, keeping the separating hyperplane unchanged. See Figures 54.8 and 54.9. Then we are reduced to *Case 1a* or *Case 2a*.

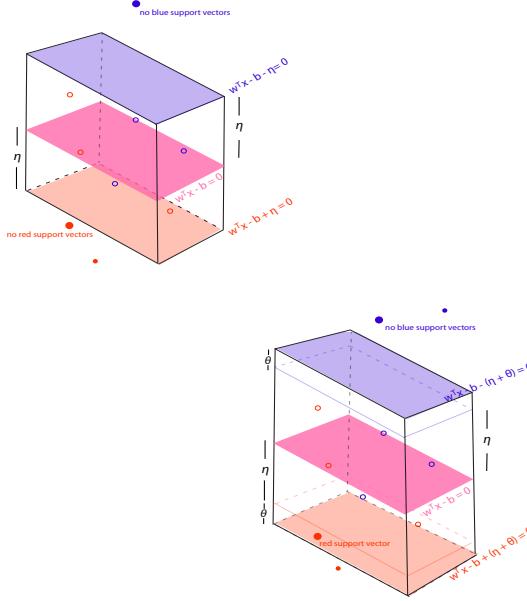

Figure 54.8: In this illustration points with errors are denoted by open circles. In the original, upper left configuration, there is no blue support vector and no red support vector. By increasing the margin, we end up with a red support vector and reduce to Case 1a.

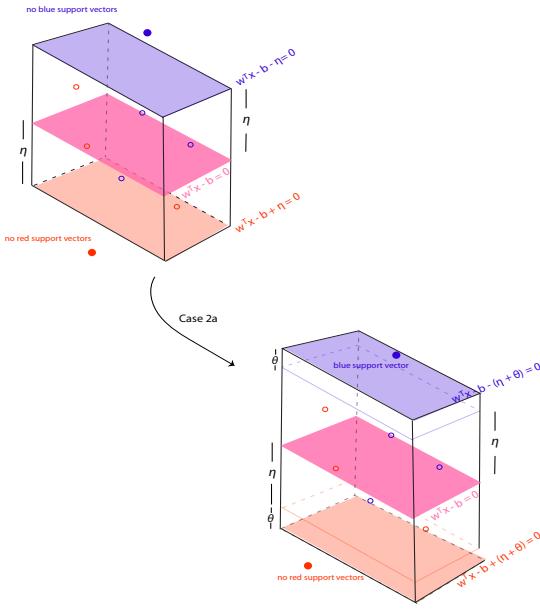

Figure 54.9: In this illustration points with errors are denoted by open circles. In the original, upper left configuration, there is no blue support vector and no red support vector. By increasing the margin, we end up with a blue support vector and reduce to Case 2a.

We have

$$\begin{aligned}
 w^T u_i - b &= \eta - \epsilon_i & \epsilon_i > 0 & i \in E_\lambda \\
 -w^T v_j + b &= \eta - \xi_j & \xi_j > 0 & j \in E_\mu \\
 w^T u_i - b &> \eta & & i \notin E_\lambda \\
 -w^T v_j + b &> \eta & & j \notin E_\mu.
 \end{aligned}$$

Let us pick θ such that

$$\theta = \min\{w^T u_i - b - \eta, -w^T v_j + b - \eta \mid i \notin E_\lambda, j \notin E_\mu\}.$$

Our hypotheses imply that $\theta > 0$. We can write

$$\begin{aligned}
 w^T u_i - b &= \eta + \theta - (\epsilon_i + \theta) & \epsilon_i > 0 & i \in E_\lambda \\
 -w^T v_j + b &= \eta + \theta - (\xi_j + \theta) & \xi_j > 0 & j \in E_\mu \\
 w^T u_i - b &\geq \eta + \theta & & i \notin E_\lambda \\
 -w^T v_j + b &\geq \eta + \theta & & j \notin E_\mu,
 \end{aligned}$$

and by the choice of θ , either

$$w^T u_i - b = \eta + \theta \quad \text{for some } i \notin E_\lambda$$

or

$$-w^\top v_j + b = \eta + \theta \quad \text{for some } j \notin E_\mu.$$

The new value of the objective function is

$$\begin{aligned} \omega(\theta) &= \frac{1}{2} w^\top w - \nu(\eta + \theta) + \frac{1}{p+q} \left(\sum_{i \in E_\lambda} (\epsilon_i + \theta) + \sum_{j \in E_\mu} (\xi_j + \theta) \right) \\ &= \frac{1}{2} w^\top w - \nu\eta + \frac{1}{p+q} \left(\sum_{i \in E_\lambda} \epsilon_i + \sum_{j \in E_\mu} \xi_j \right) - \left(\nu - \frac{p_{sf} + q_{sf}}{p+q} \right) \theta. \end{aligned}$$

Since $\max\{2p_f/(p+q), 2q_f/(p+q)\} \leq \nu$ implies that $(p_f + q_f)/(p+q) \leq \nu$ and $p_{sf} \leq p_f$, $q_{sf} \leq q_f$, we have

$$\nu - \frac{p_{sf} + q_{sf}}{p+q} \geq 0, \tag{*2}$$

and so $\omega(\theta) \leq \omega(0)$. If inequality (*2) is strict, then this contradicts the optimality of the original solution. Therefore, $\nu = (p_{sf} + q_{sf})/(p+q)$, $\omega(\theta) = \omega(0)$ and $(w, b, \eta + \theta, \epsilon + \theta, \xi + \theta)$ is an optimal solution such that either

$$w^\top u_i - b = \eta + \theta \quad \text{for some } i \notin E_\lambda$$

or

$$-w^\top v_j + b = \eta + \theta \quad \text{for some } j \notin E_\mu.$$

We are now reduced to *Case 1a* or *Case 2a*.

Case 2. We have

$$\begin{array}{ll} w^\top u_i - b \geq \eta & i \notin E_\lambda \\ -w^\top v_j + b > \eta & j \notin E_\mu. \end{array}$$

There are two subcases.

Case 2a. Assume that there is some $i \notin E_\lambda$ such that $w^\top u_i - b = \eta$. Our strategy is to increase η and decrease b by a small amount θ in such a way that some inequality becomes an equation for some $j \notin E_\mu$. Geometrically, this amounts to lowering the separating hyperplane $H_{w,b}$ and increasing the width of the slab, keeping the blue margin hyperplane unchanged. See Figure 54.10.

Let us pick θ such that

$$\theta = (1/2) \min\{-w^\top v_j + b - \eta \mid j \notin E_\mu\}.$$

Our hypotheses imply that $\theta > 0$. We can write

$$\begin{array}{lll} w^\top u_i - (b - \theta) = \eta + \theta - \epsilon_i & \epsilon_i > 0 & i \in E_\lambda \\ -w^\top v_j + b - \theta = \eta + \theta - (\xi_j + 2\theta) & \xi_j > 0 & j \in E_\mu \\ w^\top u_i - (b - \theta) \geq \eta + \theta & i \notin E_\lambda & \\ -w^\top v_j + b - \theta \geq \eta + \theta & j \notin E_\mu. & \end{array}$$

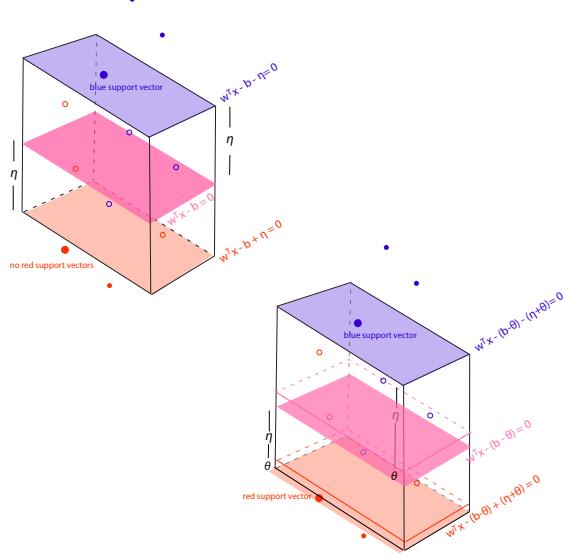

Figure 54.10: In this illustration points with errors are denoted by open circles. In the original, upper left configuration, there is no red support vector. By lowering the pink separating hyperplane and increasing the margin, we end up with a red support vector.

By hypothesis

$$w^\top u_i - (b - \theta) = \eta + \theta \quad \text{for some } i \notin E_\lambda,$$

and by the choice of θ ,

$$-w^\top v_j + b - \theta = \eta + \theta \quad \text{for some } j \notin E_\mu.$$

The new value of the objective function is

$$\begin{aligned} \omega(\theta) &= \frac{1}{2} w^\top w - \nu(\eta + \theta) + \frac{1}{p+q} \left(\sum_{i \in E_\lambda} \epsilon_i + \sum_{j \in E_\mu} (\xi_j + 2\theta) \right) \\ &= \frac{1}{2} w^\top w - \nu\eta + \frac{1}{p+q} \left(\sum_{i \in E_\lambda} \epsilon_i + \sum_{j \in E_\mu} \xi_j \right) - \left(\nu - \frac{2q_{sf}}{p+q} \right) \theta. \end{aligned}$$

The rest of the proof is similar to Case 1a with p_{sf} replaced by q_{sf} .

Case 2b. We have $w^\top u_i - b > \eta$ for all $i \notin E_\lambda$. Since by hypothesis $-w^\top v_j + b > \eta$ for all $j \notin E_\mu$, Case 2b is identical to Case 1b, and we are done. \square

A subtle point here is that Proposition 54.2 shows that if there is an optimal solution, then there is one with a blue and a red support vector, but it does not guarantee that these are support vectors of type 1. Since the dual program does not determine b and η unless

these support vectors are of type 1, from a practical point of view this proposition is not helpful.

The proof of Proposition 54.2 reveals that there are three critical values for ν :

$$\frac{2p_{sf}}{p+q}, \quad \frac{2q_{sf}}{p+q}, \quad \frac{p_{sf} + q_{sf}}{p+q}.$$

These values can be avoided by requiring the strict inequality

$$\max \left\{ \frac{2p_{sf}}{p+q}, \frac{2q_{sf}}{p+q} \right\} < \nu.$$

Then the following corollary holds.

Theorem 54.3. *For every optimal solution $(w, b, \eta, \epsilon, \xi)$ of Problem $(\text{SVM}_{s2'})$ with $w \neq 0$ and $\eta > 0$, if*

$$\max\{2p_f/(p+q), 2q_f/(p+q)\} < \nu < \min\{2p/(p+q), 2q/(p+q)\},$$

then some u_{i_0} and some v_{j_0} is a support vector.

Proof. We proceed by contradiction. Suppose that for every optimal solution with $w \neq 0$ and $\eta > 0$ no u_i is a blue support vector or no v_j is a red support vector. Since $\nu < \min\{2p/(p+q), 2q/(p+q)\}$, Proposition 54.2 holds, so there is another optimal solution. But since the critical values of ν are avoided, the proof of Proposition 54.2 shows that the value of the objective function for this new optimal solution is strictly smaller than the original optimal value, a contradiction. \square

We also have the following proposition that gives a sufficient condition implying that η and b can be found in terms of an optimal solution (λ, μ) of the dual.

Proposition 54.4. *If $(w, b, \eta, \epsilon, \xi)$ is an optimal solution of Problem $(\text{SVM}_{s2'})$ with $w \neq 0$ and $\eta > 0$, if*

$$\max\{2p_f/(p+q), 2q_f/(p+q)\} < \nu < \min\{2p/(p+q), 2q/(p+q)\},$$

then η and b can always be determined from an optimal solution (λ, μ) of the dual in terms of a single support vector.

Proof. By Theorem 54.3 some u_{i_0} and some v_{j_0} is a support vector. As we already explained, Problem $(\text{SVM}_{s2'})$ satisfies the conditions for having a zero duality gap. Therefore, for optimal solutions we have

$$L(w, \epsilon, \xi, b, \eta, \lambda, \mu, \alpha, \beta) = G(\lambda, \mu, \alpha, \beta),$$

which means that

$$\frac{1}{2}w^\top w - \nu\eta + \frac{1}{p+q} \left(\sum_{i=1}^p \epsilon_i + \sum_{j=1}^q \xi_j \right) = -\frac{1}{2} (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix},$$

and since

$$w = -X \begin{pmatrix} \lambda \\ \mu \end{pmatrix},$$

we get

$$\frac{1}{p+q} \left(\sum_{i=1}^p \epsilon_i + \sum_{j=1}^q \xi_j \right) = \nu\eta - (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix}. \quad (*)$$

Let $K_\lambda = \{i \in \{1, \dots, p\} \mid \lambda_i = K_s\}$ and $K_\mu = \{j \in \{1, \dots, q\} \mid \mu_j = K_s\}$. By definition, $p_f = |K_\lambda|$ and $q_f = |K_\mu|$ (here we assuming that $K_s = 1/(p+q)$). By complementary slackness the following equations are active:

$$\begin{aligned} w^\top u_i - b &= \eta - \epsilon_i & i \in K_\lambda \\ -w^\top v_j + b &= \eta - \xi_j & j \in K_\mu. \end{aligned}$$

But $(*)$ can be written as

$$\frac{1}{p+q} \left(\sum_{i \in K_\lambda} \epsilon_i + \sum_{j \in K_\mu} \xi_j \right) = \nu\eta - (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix}, \quad (**)$$

and since

$$\begin{aligned} \epsilon_i &= \eta - w^\top u_i + b & i \in K_\lambda \\ \xi_j &= \eta + w^\top v_j - b & j \in K_\mu, \end{aligned}$$

by substituting in the Equation $(**)$ we get

$$\left(\nu - \frac{p_f + q_f}{p+q} \right) \eta = \frac{p_f - q_f}{p+q} b + \frac{1}{p+q} w^\top \left(\sum_{i \in K_\mu} v_j - \sum_{i \in K_\lambda} u_i \right) + (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix}.$$

We also know that $w^\top u_{i_0} - b = \eta$ and $-w^\top v_{j_0} + b = \eta$ for some i_0 and some j_0 . In the first case $b = -\eta + w^\top u_{i_0}$, and by substituting b in the above equation we get the equation

$$\begin{aligned} \left(\nu - \frac{p_f + q_f}{p+q} \right) \eta &= -\frac{p_f - q_f}{p+q} \eta + \frac{p_f - q_f}{p+q} w^\top u_{i_0} + \frac{1}{p+q} w^\top \left(\sum_{i \in K_\mu} v_j - \sum_{i \in K_\lambda} u_i \right) \\ &\quad + (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix}, \end{aligned}$$

that is,

$$\begin{aligned} \left(\nu - \frac{2q_f}{p+q} \right) \eta &= \frac{p_f - q_f}{p+q} w^\top u_{i_0} + \frac{1}{p+q} w^\top \left(\sum_{i \in K_\mu} v_j - \sum_{i \in K_\lambda} u_i \right) \\ &\quad + (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix}. \end{aligned}$$

In the second case $b = \eta + w^\top v_{j_0}$, and we get the equation

$$\begin{aligned} \left(\nu - \frac{p_f + q_f}{p+q} \right) \eta &= \frac{p_f - q_f}{p+q} \eta + \frac{p_f - q_f}{p+q} w^\top v_{j_0} + \frac{1}{p+q} w^\top \left(\sum_{i \in K_\mu} v_j - \sum_{i \in K_\lambda} u_i \right) \\ &\quad + (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix}, \end{aligned}$$

that is,

$$\begin{aligned} \left(\nu - \frac{2p_f}{p+q} \right) \eta &= \frac{p_f - q_f}{p+q} w^\top v_{j_0} + \frac{1}{p+q} w^\top \left(\sum_{i \in K_\mu} v_j - \sum_{i \in K_\lambda} u_i \right) \\ &\quad + (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix}. \end{aligned}$$

We need to choose ν such that $2p_f/(p+q) - \nu \neq 0$ and $2q_f/(p+q) - \nu \neq 0$. Since by Proposition 54.1, we have $\max\{2p_f/(p+q), 2q_f/(p+q)\} \leq \nu$, it suffices to pick ν such that $\max\{2p_f/(p+q), 2q_f/(p+q)\} < \nu$. If this condition is satisfied we can solve for η , and then we find b from either $b = -\eta + w^\top u_{i_0}$ or $b = \eta + w^\top v_{j_0}$. \square

Remark: Of course the hypotheses of the proposition imply that $w^\top u_{i_0} - b = \eta$ and $-w^\top v_{j_0} + b = \eta$ for some i_0 and some j_0 . Thus we can also compute b and η using the formulae

$$\begin{aligned} b &= \frac{w^\top (u_{i_0} + v_{j_0})}{2} \\ \eta &= \frac{w^\top (u_{i_0} - v_{j_0})}{2}. \end{aligned}$$

The interest of Proposition 54.4 lies in the fact that it allows us to compute b and η knowing only a *single* support vector.

In practice we can only find support vectors of type 1 so Proposition 54.4 is useful if we can only find some blue support vector of type 1 *or* some red support vector of type 1.

As earlier, if we define I_λ and I_μ as

$$\begin{aligned} I_\lambda &= \{i \in \{1, \dots, p\} \mid 0 < \lambda_i < K_s\} \\ I_\mu &= \{j \in \{1, \dots, q\} \mid 0 < \mu_j < K_s\}, \end{aligned}$$

then we have the following cases to compute η and b .

(1) If $I_\lambda \neq \emptyset$ and $I_\mu \neq \emptyset$, then

$$b = w^\top \left(\left(\sum_{i \in I_\lambda} u_i \right) / |I_\lambda| + \left(\sum_{j \in I_\mu} v_j \right) / |I_\mu| \right) / 2$$

$$\eta = w^\top \left(\left(\sum_{i \in I_\lambda} u_i \right) / |I_\lambda| - \left(\sum_{j \in I_\mu} v_j \right) / |I_\mu| \right) / 2.$$

(2) If $I_\lambda \neq \emptyset$ and $I_\mu = \emptyset$, then

$$b = -\eta + w^\top \left(\sum_{i \in I_\lambda} u_i \right) / |I_\lambda|$$

$$((p+q)\nu - 2q_f)\eta = (p_f - q_f)w^\top \left(\sum_{i \in I_\lambda} u_i \right) / |I_\lambda| + w^\top \left(\sum_{i \in K_\mu} v_j - \sum_{i \in K_\lambda} u_i \right)$$

$$+ (p+q) (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix}.$$

(3) If $I_\lambda = \emptyset$ and $I_\mu \neq \emptyset$, then

$$b = \eta + w^\top \left(\sum_{j \in I_\mu} v_j \right) / |I_\mu|$$

$$((p+q)\nu - 2p_f)\eta = (p_f - q_f)w^\top \left(\sum_{j \in I_\mu} v_j \right) / |I_\mu| + w^\top \left(\sum_{i \in K_\mu} v_j - \sum_{i \in K_\lambda} u_i \right)$$

$$+ (p+q) (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix}.$$

The above formulae correspond to $K_s = 1/(p+q)$. In general we have to replace the rightmost $(p+q)$ by $1/K_s$.

We have examples where there is a single support vector of type 1 and $\nu = 2q_f/(p+q)$, so the above method fails. Curiously, perturbing ν slightly yields a solution with some blue support vector of type 1 and some red support vector of type 1, and so we have not yet found an example where the above method succeeds with a single support vector of type 1. This suggests to conduct some perturbation analysis but it appears to be nontrivial.

Among its advantages, the support vector machinery is conducive to finding interesting statistical bounds in terms of the *VC dimension*, a notion invented by Vapnik and Chervonenkis. We will not go into this here and instead refer the reader to Vapnik [182] (especially, Chapter 4 and Chapters 9-13).

54.8 Solving SVM ($\text{SVM}_{s2'}$) Using ADMM

In order to solve ($\text{SVM}_{s2'}$) using ADMM we need to write the matrix corresponding to the constraints in equational form,

$$\begin{aligned} \sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j &= 0 \\ \sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j - \gamma &= K_m \\ \lambda_i + \alpha_i &= K_s, \quad i = 1, \dots, p \\ \mu_j + \beta_j &= K_s, \quad j = 1, \dots, q, \end{aligned}$$

with $K_m = (p+q)K_s\nu$. This is the $(p+q+2) \times (2(p+q)+1)$ matrix A given by

$$A = \begin{pmatrix} \mathbf{1}_p^\top & -\mathbf{1}_q^\top & 0_p^\top & 0_q^\top & 0 \\ \mathbf{1}_p^\top & \mathbf{1}_q^\top & 0_p^\top & 0_q^\top & -1 \\ I_p & 0_{p,q} & I_p & 0_{p,q} & 0_p \\ 0_{q,p} & I_q & 0_{q,p} & I_q & 0_q \end{pmatrix}.$$

Observe the remarkable analogy with the matrix arising in ν -regression in Section 56.3, except that $p = q = m$ and that -1 is replaced by $+1$. We leave it as an exercise to prove that A has rank $p+q+2$. The right-hand side is

$$c = \begin{pmatrix} 0 \\ K_m \\ K_s \mathbf{1}_{p+q} \end{pmatrix}.$$

The symmetric positive semidefinite $(p+q) \times (p+q)$ matrix P defining the quadratic functional is

$$P = X^\top X, \quad \text{with} \quad X = \begin{pmatrix} -u_1 & \cdots & -u_p & v_1 & \cdots & v_q \end{pmatrix},$$

and

$$q = 0_{p+q}.$$

Since there are $2(p+q)+1$ Lagrange multipliers $(\lambda, \mu, \alpha, \beta, \gamma)$, the $(p+q) \times (p+q)$ matrix $X^\top X$ must be augmented with zero's to make it a $(2(p+q)+1) \times (2(p+q)+1)$ matrix P_a given by

$$P_a = \begin{pmatrix} X^\top X & 0_{p+q,p+q+1} \\ 0_{p+q+1,p+q} & 0_{p+q+1,p+q+1} \end{pmatrix},$$

and similarly q is augmented with zeros as the vector $q_a = 0_{2(p+q)+1}$.

As we mentioned in Section 54.5, since $\eta \geq 0$ for an optimal solution, we can drop the constraint $\eta \geq 0$ from the primal problem. In this case there are $2(p+q)$ Lagrange multipliers

$(\lambda, \mu, \alpha, \beta)$. It is easy to see that the objective function of the dual is unchanged and the set of constraints is

$$\begin{aligned} \sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j &= 0 \\ \sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j &= K_m \\ \lambda_i + \alpha_i &= K_s, \quad i = 1, \dots, p \\ \mu_j + \beta_j &= K_s, \quad j = 1, \dots, q, \end{aligned}$$

with $K_m = (p+q)K_s\nu$. The constraint matrix corresponding to this system of equations is the $(p+q+2) \times 2(p+q)$ matrix A_2 given by

$$A_2 = \begin{pmatrix} \mathbf{1}_p^\top & -\mathbf{1}_q^\top & 0_p^\top & 0_q^\top \\ \mathbf{1}_p^\top & \mathbf{1}_q^\top & 0_p^\top & 0_q^\top \\ I_p & 0_{p,q} & I_p & 0_{p,q} \\ 0_{q,p} & I_q & 0_{q,p} & I_q \end{pmatrix}.$$

We leave it as an exercise to prove that A_2 has rank $p+q+2$. The right-hand side is

$$c_2 = \begin{pmatrix} 0 \\ K_m \\ K_s \mathbf{1}_{p+q} \end{pmatrix}.$$

The symmetric positive semidefinite $(p+q) \times (p+q)$ matrix P defining the quadratic functional is

$$P = X^\top X, \quad \text{with} \quad X = (-u_1 \ \cdots \ -u_p \ v_1 \ \cdots \ v_q),$$

and

$$q = 0_{p+q}.$$

Since there are $2(p+q)$ Lagrange multipliers the $(p+q) \times (p+q)$ matrix $X^\top X$ must be augmented with zero's to make it a $2(p+q) \times 2(p+q)$ matrix P_{2a} given by

$$P_{2a} = \begin{pmatrix} X^\top X & 0_{p+q,p+q} \\ 0_{p+q,p+q} & 0_{p+q,p+q} \end{pmatrix},$$

and similarly q is augmented with zeros as the vector $q_{2a} = 0_{2(p+q)}$.

The **Matlab** programs implementing the above method are given in Appendix B, Section B.2. We ran our program on two sets of 30 points each generated at random using the following code which calls the function `runSVMs2pbv3`:

```

rho = 10;
u16 = 10.1*randn(2,30)+7 ;
v16 = -10.1*randn(2,30)-7;
[~,~,~,~,~,~,w3] = runSVMs2pbv3(0.37,rho,u16,v16,1/60)

```

We picked $K = 1/60$ and various values of ν starting with $\nu = 0.37$, which appears to be the smallest value for which the method converges; see Figure 54.11.

In this example, $p_f = 10, q_f = 11, p_m = 12, q_m = 12$. The quadratic solver converged after 8121 steps to reach primal and dual residuals smaller than 10^{-10} .

Reducing ν below $\nu = 0.37$ has the effect that p_f, q_f, p_m, q_m decrease but the following situation arises. Shrinking η a little bit has the effect that $p_f = 9, q_f = 10, p_m = 10, q_m = 11$. Then $\max\{p_f, q_f\} = \min\{p_m, q_m\} = 10$, so the only possible value for ν is $\nu = 20/60 = 1/3 = 0.3333333\dots$. When we run our program with $\nu = 1/3$, it returns a value of η less than 10^{-13} and a value of w whose components are also less than 10^{-13} . This is probably due to numerical precision. Values of ν less than $1/3$ cause the same problem. It appears that the geometry of the problem constrains the values of p_f, q_f, p_m, q_m in such a way that it has no solution other than $w = 0$ and $\eta = 0$.

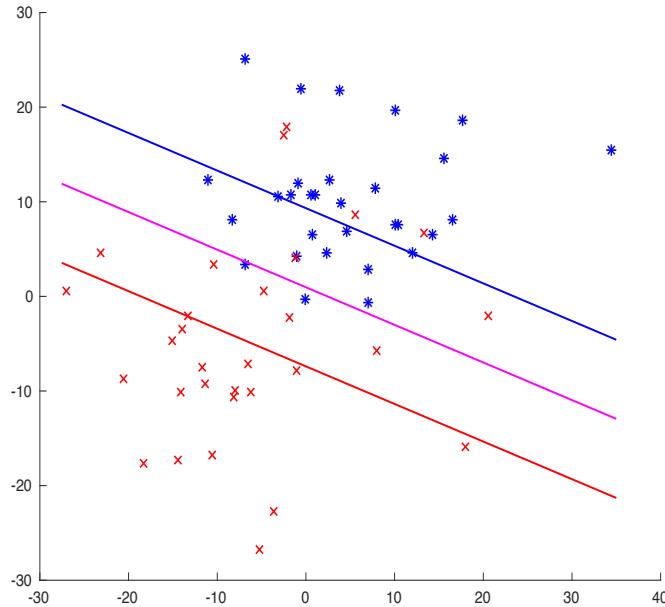

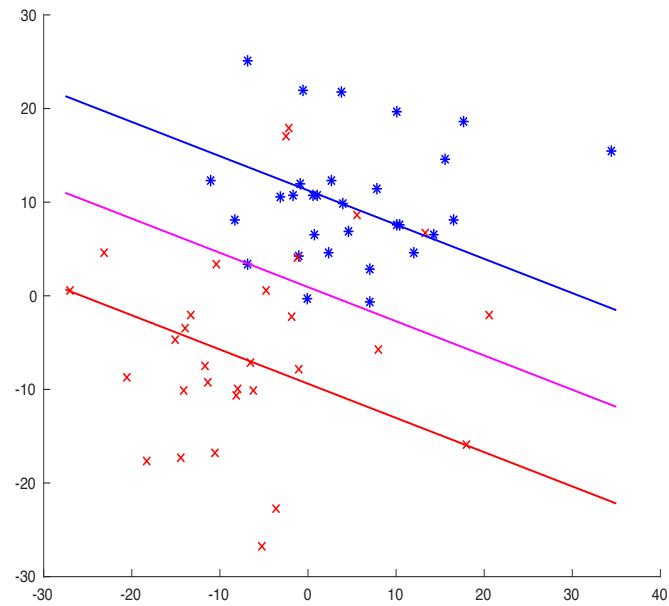

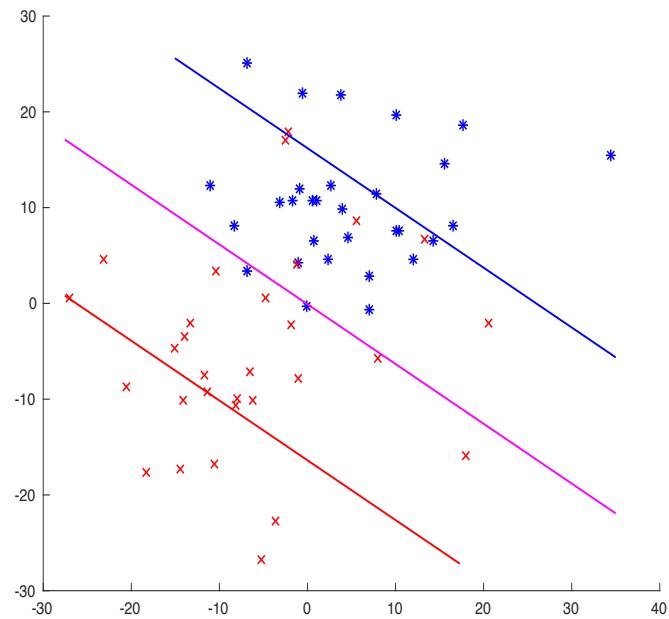

Figure 54.11: Running $(\text{SVM}_{s2'})$ on two sets of 30 points; $\nu = 0.37$.

Figure 54.12 shows the result of running the program with $\nu = 0.51$. We have $p_f = 15, q_f = 16, p_m = 16, q_m = 16$. Interestingly, for $\nu = 0.5$, we run into the singular situation where there is only one support vector and $\nu = 2p_f/(p + q)$.

Figure 54.12: Running ($\text{SVM}_{s2'}$) on two sets of 30 points; $\nu = 0.51$.Figure 54.13: Running ($\text{SVM}_{s2'}$) on two sets of 30 points; $\nu = 0.71$.

Next Figure 54.13 shows the result of running the program with $\nu = 0.71$. We have

$p_f = 21, q_f = 21, p_m = 22, q_m = 23$. Interestingly, for $\nu = 0.7$, we run into the singular situation where there are no support vectors.

For our next to the last run, Figure 54.14 shows the result of running the program with $\nu = 0.95$. We have $p_f = 28, q_f = 28, p_m = 29, q_m = 29$.

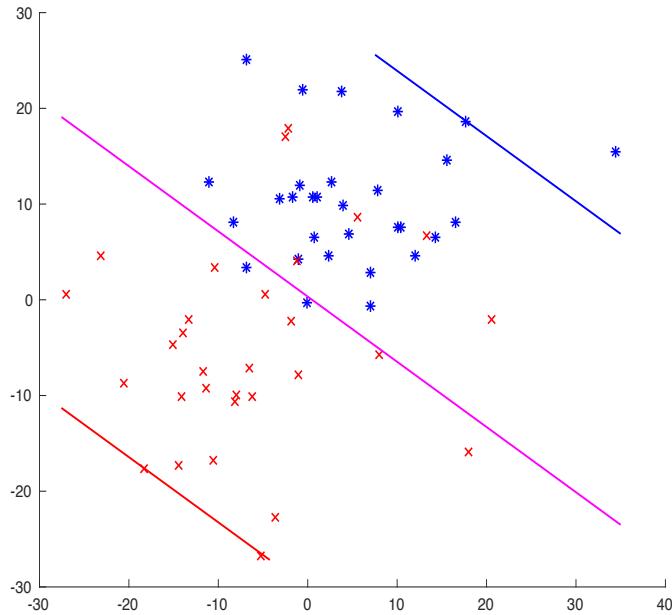

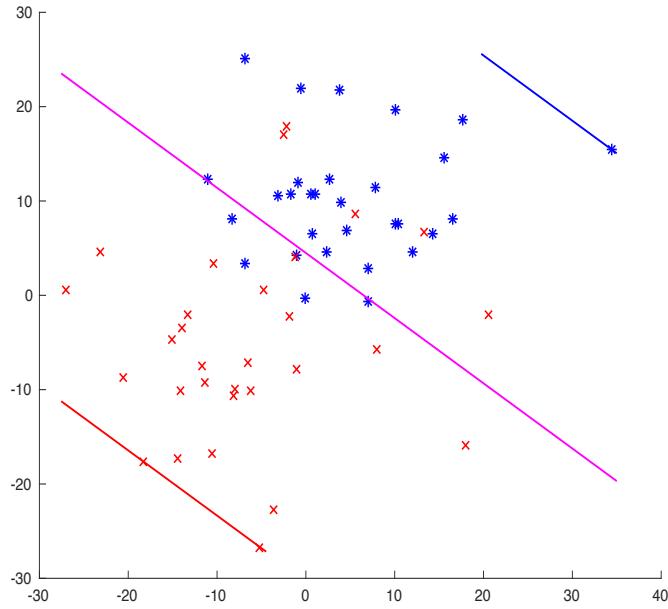

Figure 54.14: Running $(\text{SVM}_{s2'})$ on two sets of 30 points; $\nu = 0.95$.

Figure 54.15 shows the result of running the program with $\nu = 0.97$. We have $p_f = 29, q_f = 29, p_m = 30, q_m = 30$, which shows that the largest margin has been achieved. However, after 80000 iterations the dual residual is less than 10^{-12} but the primal residual is approximately 10^{-4} (our tolerance for convergence is 10^{-10} , which is quite high). Nevertheless the result is visually very good.

54.9 Soft Margin Support Vector Machines; (SVM_{s3})

In this section we consider a variation of Problem $(\text{SVM}_{s2'})$ by adding the term $(1/2)b^2$ to the objective function. The result is that in minimizing the Lagrangian to find the dual function G , not just w but also b is determined and η is determined under a mild condition on ν . We also suppress the constraint $\eta \geq 0$ which turns out to be redundant.

Figure 54.15: Running ($\text{SVM}_{s2'}$) on two sets of 30 points; $\nu = 0.97$.

Soft margin SVM (SVM_{s3}):

$$\text{minimize} \quad \frac{1}{2} w^\top w + \frac{1}{2} b^2 + (p+q)K_s \left(-\nu\eta + \frac{1}{p+q} (\epsilon^\top \xi^\top) \mathbf{1}_{p+q} \right)$$

subject to

$$\begin{aligned} w^\top u_i - b &\geq \eta - \epsilon_i, \quad \epsilon_i \geq 0 \quad i = 1, \dots, p \\ -w^\top v_j + b &\geq \eta - \xi_j, \quad \xi_j \geq 0 \quad j = 1, \dots, q. \end{aligned}$$

To simplify the presentation we assume that $K_s = 1/(p+q)$. When writing a computer program it is more convenient to assume that K_s is arbitrary. In this case, ν needs to be replaced by $(p+q)K_s\nu$ in all the formulae.

The Lagrangian $L(w, \epsilon, \xi, b, \eta, \lambda, \mu, \alpha, \beta)$ with $\lambda, \alpha \in \mathbb{R}_+^p$, $\mu, \beta \in \mathbb{R}_+^q$ is given by

$$\begin{aligned} L(w, \epsilon, \xi, b, \eta, \lambda, \mu, \alpha, \beta) &= \frac{1}{2} w^\top w + w^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + \frac{b^2}{2} - \nu\eta + K_s(\epsilon^\top \mathbf{1}_p + \xi^\top \mathbf{1}_q) - \epsilon^\top (\lambda + \alpha) \\ &\quad - \xi^\top (\mu + \beta) + b(\mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu) + \eta(\mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu) \\ &= \frac{1}{2} w^\top w + w^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + \frac{b^2}{2} + b(\mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu) + \eta(\mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu - \nu) \\ &\quad + \epsilon^\top (K_s \mathbf{1}_p - (\lambda + \alpha)) + \xi^\top (K_s \mathbf{1}_q - (\mu + \beta)). \end{aligned}$$

To find the dual function $G(\lambda, \mu, \alpha, \beta)$, we minimize $L(w, \epsilon, \xi, b, \eta, \lambda, \mu, \alpha, \beta)$ with respect to w, ϵ, ξ, b , and η . Since the Lagrangian is convex and $(w, \epsilon, \xi, b, \eta) \in \mathbb{R}^n \times \mathbb{R}^p \times \mathbb{R}^q \times \mathbb{R} \times \mathbb{R}$, a convex open set, by Theorem 40.13, the Lagrangian has a minimum in $(w, \epsilon, \xi, b, \eta)$ iff $\nabla L_{w,\epsilon,\xi,b,\eta} = 0$, so we compute its gradient with respect to $w, \epsilon, \xi, b, \eta$, and we get

$$\nabla L_{w,\epsilon,\xi,b,\eta} = \begin{pmatrix} X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + w \\ K_s \mathbf{1}_p - (\lambda + \alpha) \\ K_s \mathbf{1}_q - (\mu + \beta) \\ b + \mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu \\ \mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu - \nu \end{pmatrix}.$$

By setting $\nabla L_{w,\epsilon,\xi,b,\eta} = 0$ we get the equations

$$w = -X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \quad (*_w)$$

$$\begin{aligned} \lambda + \alpha &= K_s \mathbf{1}_p \\ \mu + \beta &= K_s \mathbf{1}_q \\ \mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu &= \nu, \end{aligned}$$

and

$$b = -(\mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu). \quad (*_b)$$

The second and third equations are equivalent to the box constraints

$$0 \leq \lambda_i, \mu_j \leq K_s, \quad i = 1, \dots, p, j = 1, \dots, q.$$

Since we assumed that the primal problem has an optimal solution with $w \neq 0$, we have

$$X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \neq 0.$$

Plugging back w from $(*_w)$ and b from $(*_b)$ into the Lagrangian, we get

$$\begin{aligned} G(\lambda, \mu, \alpha, \beta) &= \frac{1}{2} (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + \frac{1}{2} b^2 - b^2 \\ &= -\frac{1}{2} (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - \frac{1}{2} b^2 \\ &= -\frac{1}{2} (\lambda^\top \mu^\top) \left(X^\top X + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}, \end{aligned}$$

so the dual function is independent of α, β and is given by

$$G(\lambda, \mu) = -\frac{1}{2} (\lambda^\top \quad \mu^\top) \left(X^\top X + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}.$$

The dual program is given by

$$\text{maximize} \quad -\frac{1}{2} (\lambda^\top \quad \mu^\top) \left(X^\top X + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}$$

subject to

$$\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j = \nu$$

$$0 \leq \lambda_i \leq K_s, \quad i = 1, \dots, p$$

$$0 \leq \mu_j \leq K_s, \quad j = 1, \dots, q.$$

Finally, the dual program is equivalent to the following minimization program:

Dual of the Soft margin SVM (SVM_{s3}):

$$\text{minimize} \quad \frac{1}{2} (\lambda^\top \quad \mu^\top) \left(X^\top X + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}$$

subject to

$$\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j = \nu$$

$$0 \leq \lambda_i \leq K_s, \quad i = 1, \dots, p$$

$$0 \leq \mu_j \leq K_s, \quad j = 1, \dots, q.$$

The classification of the points u_i and v_j in terms of the values of λ and μ and Definition 54.2 and Definition 54.3 are unchanged.

It is shown in Section 54.12 how the dual program is solved using ADMM from Section 52.6. If the primal problem is solvable, this yields solutions for λ and μ . Once a solution for λ and μ is obtained, we have

$$w = -X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = \sum_{i=1}^p \lambda_i u_i - \sum_{j=1}^q \mu_j v_j$$

$$b = -(\mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu) = -\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j.$$

We can compute η using duality. As we said earlier, the hypotheses of Theorem 50.17(2) hold, so if the primal problem (SVM_{s3}) has an optimal solution with $w \neq 0$, then the dual

problem has a solution too, and the duality gap is zero. Therefore, for optimal solutions we have

$$L(w, \epsilon, \xi, b, \eta, \lambda, \mu, \alpha, \beta) = G(\lambda, \mu, \alpha, \beta),$$

which means that

$$\begin{aligned} \frac{1}{2}w^\top w + \frac{b^2}{2} - (p+q)K_s\nu\eta + K_s\left(\sum_{i=1}^p \epsilon_i + \sum_{j=1}^q \xi_j\right) \\ = -\frac{1}{2}(\lambda^\top \mu^\top) \left(X^\top X + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix}\right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}. \end{aligned}$$

We can use the above equation to determine η .

Since

$$\frac{1}{2}w^\top w + \frac{b^2}{2} = \frac{1}{2}(\lambda^\top \mu^\top) \left(X^\top X + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix}\right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix},$$

we get

$$(p+q)K_s\nu\eta = K_s\left(\sum_{i=1}^p \epsilon_i + \sum_{j=1}^q \xi_j\right) + (\lambda^\top \mu^\top) \left(X^\top X + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix}\right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}. \quad (*)$$

Since

$$X^\top X + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix}$$

is positive semidefinite, we confirm that $\eta \geq 0$.

Since nonzero ϵ_i and ξ_j may only occur for vectors u_i and v_j that fail the margin, namely $\lambda_i = K_s$, $\mu_j = K_s$, the corresponding constraints are active and we can solve for ϵ_i and ξ_j in terms of b and η . Let K_λ and K_μ be the sets of indices corresponding to points failing the margin,

$$\begin{aligned} K_\lambda &= \{i \in \{1, \dots, p\} \mid \lambda_i = K_s\} \\ K_\mu &= \{j \in \{1, \dots, q\} \mid \mu_j = K_s\}. \end{aligned}$$

By definition $p_f = |K_\lambda|$, $q_f = |K_\mu|$. Then for every $i \in K_\lambda$ we have

$$\epsilon_i = \eta + b - w^\top u_i$$

and for every $j \in K_\mu$ we have

$$\xi_j = \eta - b + w^\top v_j.$$

Using the above formulae we obtain

$$\begin{aligned} \sum_{i=1}^p \epsilon_i + \sum_{j=1}^q \xi_j &= \sum_{i \in K_\lambda} \epsilon_i + \sum_{j \in K_\mu} \xi_j \\ &= \sum_{i \in K_\lambda} (\eta + b - w^\top u_i) + \sum_{j \in K_\mu} (\eta - b + w^\top v_j) \\ &= (p_f + q_f)\eta + (p_f - q_f)b + w^\top \left(\sum_{j \in K_\mu} v_j - \sum_{i \in K_\lambda} u_i \right) \end{aligned}$$

Substituting this expression in (*) we obtain

$$\begin{aligned} (p+q)K_s\nu\eta &= K_s \left(\sum_{i=1}^p \epsilon_i + \sum_{j=1}^q \xi_j \right) + (\lambda^\top \mu^\top) \left(X^\top X + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ &= K_s \left((p_f + q_f)\eta + (p_f - q_f)b + w^\top \left(\sum_{j \in K_\mu} v_j - \sum_{i \in K_\lambda} u_i \right) \right) \\ &\quad + (\lambda^\top \mu^\top) \left(X^\top X + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}, \end{aligned}$$

which yields

$$\begin{aligned} ((p+q)\nu - p_f - q_f)\eta &= (p_f - q_f)b + w^\top \left(\sum_{j \in K_\mu} v_j - \sum_{i \in K_\lambda} u_i \right) \\ &\quad + \frac{1}{K_s} (\lambda^\top \mu^\top) \left(X^\top X + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}. \end{aligned}$$

We show in Proposition 54.5 that $p_f + q_f \leq (p+q)\nu$, so if $\nu > (p_f + q_f)/(p+q)$, we can solve for η in terms of b , w , and λ, μ . But b and w are expressed in terms of λ, μ as

$$\begin{aligned} w &= -X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ b &= -\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j = -\mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu \end{aligned}$$

so η is also expressed in terms of λ, μ .

The condition $\nu > (p_f + q_f)/(p+q)$ cannot be satisfied if $p_f + q_f = p+q$, but in this case all points fail the margin, which indicates that δ is too big, so we reduce ν and try again.

Remark: The equation

$$\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j = \nu$$

implies that either there is some i_0 such that $\lambda_{i_0} > 0$ or there is some j_0 such that $\mu_{j_0} > 0$, which implies that $p_m + q_m \geq 1$.

Another way to compute η is to assume the Standard Margin Hypothesis for (SVM_{s3}). Under the **Standard Margin Hypothesis** for (SVM_{s3}), either there is some i_0 such that $0 < \lambda_{i_0} < K_s$ or there is some j_0 such that $0 < \mu_{j_0} < K_s$, in other words, there is some support vector of type 1. By the complementary slackness conditions $\epsilon_{i_0} = 0$ or $\xi_{j_0} = 0$, so we have

$$w^\top u_{i_0} - b = \eta, \quad \text{or} \quad -w^\top v_{j_0} + b = \eta,$$

and we can solve for η .

Due to numerical instability, when writing a computer program it is preferable to compute the lists of indices I_λ and I_μ given by

$$\begin{aligned} I_\lambda &= \{i \in \{1, \dots, p\} \mid 0 < \lambda_i < K_s\} \\ I_\mu &= \{j \in \{1, \dots, q\} \mid 0 < \mu_j < K_s\}. \end{aligned}$$

Then it is easy to see that we can compute η using the following averaging formulae: If $I_\lambda \neq \emptyset$, then

$$\eta = w^\top \left(\sum_{i \in I_\lambda} u_i \right) / |I_\lambda| - b,$$

and if $I_\mu \neq \emptyset$, then

$$\eta = b - w^\top \left(\sum_{j \in I_\mu} v_j \right) / |I_\mu|.$$

Theoretically the condition $\nu > (p_f + q_f)/(p + q)$ is less restrictive than the **Standard Margin Hypothesis** but in practice we have never observed an example for which $\nu > (p_f + q_f)/(p + q)$ and yet the **Standard Margin Hypothesis** fails.

The “kernelized” version of Problem (SVM_{s3}) is the following:

Soft margin kernel SVM (SVM_{s3}):

$$\begin{aligned} \text{minimize} \quad & \frac{1}{2} \langle w, w \rangle + \frac{1}{2} b^2 - \nu \eta + K_s (\epsilon^\top \quad \xi^\top) \mathbf{1}_{p+q} \\ \text{subject to} \quad & \begin{aligned} \langle w, \varphi(u_i) \rangle - b \geq \eta - \epsilon_i, \quad \epsilon_i \geq 0 & \quad i = 1, \dots, p \\ -\langle w, \varphi(v_j) \rangle + b \geq \eta - \xi_j, \quad \xi_j \geq 0 & \quad j = 1, \dots, q, \end{aligned} \end{aligned}$$

with $K_s = 1/(p + q)$.

Tracing through the derivation of the dual program, we obtain

Dual of the Soft margin kernel SVM (SVM_{s3}):

$$\text{minimize} \quad \frac{1}{2} (\lambda^\top - \mu^\top) \left(\mathbf{K} + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}$$

subject to

$$\begin{aligned} \sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j &= \nu \\ 0 \leq \lambda_i \leq K_s, \quad i &= 1, \dots, p \\ 0 \leq \mu_j \leq K_s, \quad j &= 1, \dots, q, \end{aligned}$$

where \mathbf{K} is the kernel matrix of Section 54.1.

We obtain

$$\begin{aligned} w &= \sum_{i=1}^p \lambda_i \varphi(u_i) - \sum_{j=1}^q \mu_j \varphi(v_j) \\ b &= -\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j. \end{aligned}$$

The classification function

$$f(x) = \text{sgn}(\langle w, \varphi(x) \rangle - b)$$

is given by

$$f(x) = \text{sgn}\left(\sum_{i=1}^p \lambda_i (\kappa(u_i, x) + 1) - \sum_{j=1}^q \mu_j (\kappa(v_j, x) + 1)\right).$$

54.10 Classification of the Data Points in Terms of ν (SVM_{s3})

The equations (\dagger) and the box inequalities

$$0 \leq \lambda_i \leq K_s, \quad 0 \leq \mu_j \leq K_s$$

also imply the following facts (recall that $\delta = \eta / \|w\|$):

Proposition 54.5. *If Problem (SVM_{s3}) has an optimal solution with $w \neq 0$ and $\eta > 0$ then the following facts hold:*

- (1) *Let p_f be the number of points u_i such that $\lambda_i = K_s$, and let q_f the number of points v_j such that $\mu_j = K_s$. Then $p_f + q_f \leq (p + q)\nu$.*

(2) Let p_m be the number of points u_i such that $\lambda_i > 0$, and let q_m the number of points v_j such that $\mu_j > 0$. Then $p_m + q_m \geq (p + q)\nu$. We have $p_m + q_m \geq 1$.

(3) If $p_f \geq 1$ or $q_f \geq 1$, then $\nu \geq 1/(p + q)$.

Proof. (1) Recall that for an optimal solution with $w \neq 0$ and $\eta > 0$ we have the equation

$$\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j = \nu.$$

Since there are p_f points u_i such that $\lambda_i = K_s = 1/(p + q)$ and q_f points v_j such that $\mu_j = K_s = 1/(p + q)$, we have

$$\nu = \sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j \geq \frac{p_f + q_f}{p + q},$$

so

$$p_f + q_f \leq \nu(p + q).$$

(2) If

$$I_{\lambda>0} = \{i \in \{1, \dots, p\} \mid \lambda_i > 0\} \quad \text{and} \quad p_m = |I_{\lambda>0}|$$

and

$$I_{\mu>0} = \{j \in \{1, \dots, q\} \mid \mu_j > 0\} \quad \text{and} \quad q_m = |I_{\mu>0}|,$$

then

$$\nu = \sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j = \sum_{i \in I_{\lambda>0}} \lambda_i + \sum_{j \in I_{\mu>0}} \mu_j,$$

and since $\lambda_i, \mu_j \leq K_s = 1/(p + q)$, we have

$$\nu = \sum_{i \in I_{\lambda>0}} \lambda_i + \sum_{j \in I_{\mu>0}} \mu_j \leq \frac{p_m + q_m}{p + q},$$

which yields

$$p_m + q_m \geq \nu(p + q).$$

We already noted earlier that $p_m + q_m \geq 1$.

(3) This follows immediately from (1). □

Note that if ν is chosen so that $\nu < 1/(p + q)$, then $p_f = q_f = 0$, which means that none of the data points are misclassified; in other words, the u_i s and v_j s are linearly separable. Thus we see that if the u_i s and v_j s are not linearly separable we must pick ν such that $1/(p + q) \leq \nu \leq 1$ for the method to succeed. In fact, by Proposition 54.5, we must choose ν so that

$$\frac{p_f + q_f}{p + q} \leq \nu \leq \frac{p_m + q_m}{p + q}.$$

Furthermore, in order to be able to determine b , we must have the strict inequality

$$\frac{p_f + q_f}{p + q} < \nu.$$

54.11 Existence of Support Vectors for (SVM_{s3})

The following proposition is the version of Proposition 54.2 for Problem (SVM_{s3}).

Proposition 54.6. *For every optimal solution $(w, b, \eta, \epsilon, \xi)$ of Problem (SVM_{s3}) with $w \neq 0$ and $\eta > 0$, if $\nu < 1$ and if no u_i is a support vector and no v_j is a support vector, then there is another optimal solution such that some u_{i_0} or some v_{j_0} is a support vector.*

Proof. We may assume that $K_s = 1/(p + q)$ and we proceed by contradiction. Thus we assume that for all $i \in \{1, \dots, p\}$, if $\epsilon_i = 0$, then the constraint $w^\top u_i - b \geq \eta$ is not active, namely $w^\top u_i - b > \eta$, and for all $j \in \{1, \dots, q\}$, if $\xi_j = 0$, then the constraint $-w^\top v_j + b \geq \eta$ is not active, namely $-w^\top v_j + b > \eta$.

Let $E_\lambda = \{i \in \{1, \dots, p\} \mid \epsilon_i > 0\}$ and let $E_\mu = \{j \in \{1, \dots, q\} \mid \xi_j > 0\}$. By definition, $p_{sf} = |E_\lambda|$, $q_{sf} = |E_\mu|$, $p_{sf} \leq p_f$ and $q_{sf} \leq q_f$, so by Proposition 54.1,

$$\frac{p_{sf} + q_{sf}}{p + q} \leq \frac{p_f + q_f}{p + q} \leq \nu.$$

Therefore, if $\nu < 1$, then $p_{sf} + q_{sf} < p + q$, which implies that either there is some $i \notin E_\lambda$ such that $\epsilon_i = 0$ or there is some $j \notin E_\mu$ such that $\xi_j = 0$.

By complementary slackness all the constraints for which $i \in E_\lambda$ and $j \in E_\mu$ are active, so our hypotheses are

$$\begin{array}{lll} w^\top u_i - b = \eta - \epsilon_i & \epsilon_i > 0 & i \in E_\lambda \\ -w^\top v_j + b = \eta - \xi_j & \xi_j > 0 & j \in E_\mu \\ w^\top u_i - b > \eta & & i \notin E_\lambda \\ -w^\top v_j + b > \eta & & j \notin E_\mu, \end{array}$$

and either there is some $i \notin E_\lambda$ or there is some $j \notin E_\mu$. Our strategy, as illustrated in Figures 54.8 and 54.9, is to increase the width η of the slab keeping the separating hyperplane unchanged. Let us pick θ such that

$$\theta = \min\{w^\top u_i - b - \eta, -w^\top v_j + b - \eta \mid i \notin E_\lambda, j \notin E_\mu\}.$$

Our hypotheses imply that $\theta > 0$. We can write

$$\begin{array}{lll} w^\top u_i - b = \eta + \theta - (\epsilon_i + \theta) & \epsilon_i + \theta > 0 & i \in E_\lambda \\ -w^\top v_j + b = \eta + \theta - (\xi_j + \theta) & \xi_j + \theta > 0 & j \in E_\mu \\ w^\top u_i - b \geq \eta + \theta & & i \notin E_\lambda \\ -w^\top v_j + b \geq \eta + \theta & & j \notin E_\mu, \end{array}$$

and by the choice of θ , either

$$w^\top u_i - b = \eta + \theta \quad \text{for some } i \notin E_\lambda$$

or

$$-w^\top v_j + b = \eta + \theta \quad \text{for some } j \notin E_\mu.$$

The original value of the objective function is

$$\omega(0) = \frac{1}{2}w^\top w + \frac{1}{2}b^2 - \nu\eta + \frac{1}{p+q} \left(\sum_{i \in E_\lambda} \epsilon_i + \sum_{j \in E_\mu} \xi_j \right),$$

and the new value is

$$\begin{aligned} \omega(\theta) &= \frac{1}{2}w^\top w + \frac{1}{2}b^2 - \nu(\eta + \theta) + \frac{1}{p+q} \left(\sum_{i \in E_\lambda} (\epsilon_i + \theta) + \sum_{j \in E_\mu} (\xi_j + \theta) \right) \\ &= \frac{1}{2}w^\top w + \frac{1}{2}b^2 - \nu\eta + \frac{1}{p+q} \left(\sum_{i \in E_\lambda} \epsilon_i + \sum_{j \in E_\mu} \xi_j \right) - \left(\nu - \frac{p_{sf} + q_{sf}}{p+q} \right) \theta. \end{aligned}$$

By Proposition 54.1,

$$\frac{p_{sf} + q_{sf}}{p+q} \leq \frac{p_f + q_f}{p+q} \leq \nu,$$

so

$$\nu - \frac{p_{sf} + q_{sf}}{p+q} \geq 0,$$

and so $\omega(\theta) \leq \omega(0)$. If the inequality is strict, then this contradicts the optimality of the original solution. Therefore, $\omega(\theta) = \omega(0)$ and $(w, b, \eta + \theta, \epsilon + \theta, \xi + \theta)$ is an optimal solution such that either

$$w^\top u_i - b = \eta + \theta \quad \text{for some } i \notin E_\lambda$$

or

$$-w^\top v_j + b = \eta + \theta \quad \text{for some } j \notin E_\mu,$$

as desired. \square

Proposition 54.6 cannot be strengthened to claim that there is some support vector u_{i_0} and some support vector v_{j_0} . We found examples for which the above condition fails for ν large enough.

The proof of Proposition 54.6 reveals that $(p_{sf} + q_{sf})/(p+q)$ is a critical value for ν . if this value is avoided we have the following corollary.

Theorem 54.7. *For every optimal solution $(w, b, \eta, \epsilon, \xi)$ of Problem (SVM_{s3}) with $w \neq 0$ and $\eta > 0$, if*

$$(p_{sf} + q_{sf})/(p+q) < \nu < 1,$$

then some u_{i_0} or some v_{j_0} is a support vector.

The proof proceeds by contradiction using Proposition 54.6 (for a very similar proof, see the proof of Theorem 54.3).

54.12 Solving SVM (SVM_{s3}) Using ADMM

In order to solve (SVM_{s3}) using ADMM we need to write the matrix corresponding to the constraints in equational form,

$$\begin{aligned} \sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j &= K_m \\ \lambda_i + \alpha_i &= K_s, \quad i = 1, \dots, p \\ \mu_j + \beta_j &= K_s, \quad j = 1, \dots, q \end{aligned}$$

with $K_m = (p+q)K_s\nu$. This is the $(p+q+1) \times 2(p+q)$ matrix A given by

$$A = \begin{pmatrix} \mathbf{1}_p^\top & \mathbf{1}_q^\top & 0_p^\top & 0_q^\top \\ I_p & 0_{p,q} & I_p & 0_{p,q} \\ 0_{q,p} & I_q & 0_{q,p} & I_q \end{pmatrix}.$$

We leave it as an exercise to prove that A has rank $p+q+1$. The right-hand side is

$$c = \begin{pmatrix} K_m \\ K_s \mathbf{1}_{p+q} \end{pmatrix}.$$

The symmetric positive semidefinite $(p+q) \times (p+q)$ matrix P defining the quadratic functional is

$$P = X^\top X + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix}, \quad \text{with } X = (-u_1 \ \cdots \ -u_p \ v_1 \ \cdots \ v_q),$$

and

$$q = 0_{p+q}.$$

Since there are $2(p+q)$ Lagrange multipliers $(\lambda, \mu, \alpha, \beta)$, the $(p+q) \times (p+q)$ matrix P must be augmented with zero's to make it a $2(p+q) \times 2(p+q)$ matrix P_a given by

$$P_a = \begin{pmatrix} P & 0_{p+q,p+q} \\ 0_{p+q,p+q} & 0_{p+q,p+q} \end{pmatrix},$$

and similarly q is augmented with zeros as the vector

$$q_a = 0_{2(p+q)}.$$

The **Matlab** programs implementing the above method are given in Appendix B, Section B.3. We ran our program on the same input data points used in Section 54.8, namely

```
u16 = 10.1*randn(2,30)+7 ;
v16 = -10.1*randn(2,30)-7;
[~,~,~,~,~,~,w3] = runSVMs3b(0.365,rho,u16,v16,1/60)
```

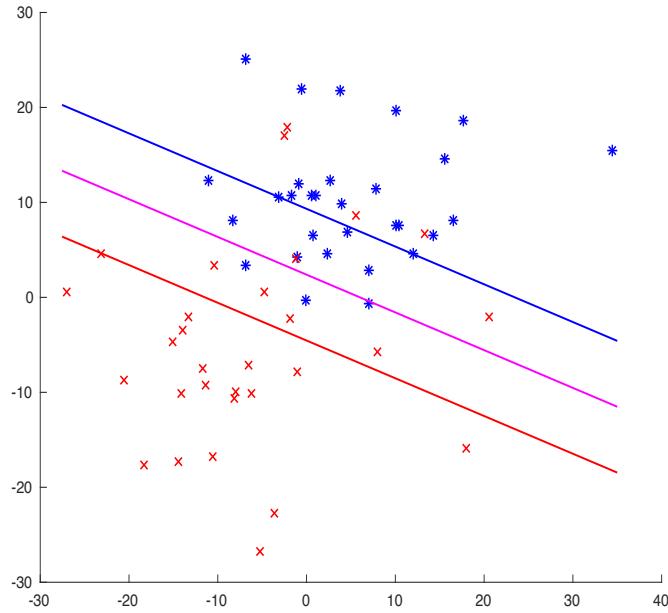

Figure 54.16: Running (SVM_{s3}) on two sets of 30 points; $\nu = 0.365$.

We picked $K = 1/60$ and various values of ν starting with $\nu = 0.365$, which appears to be the smallest value for which the method converges; see Figure 54.16.

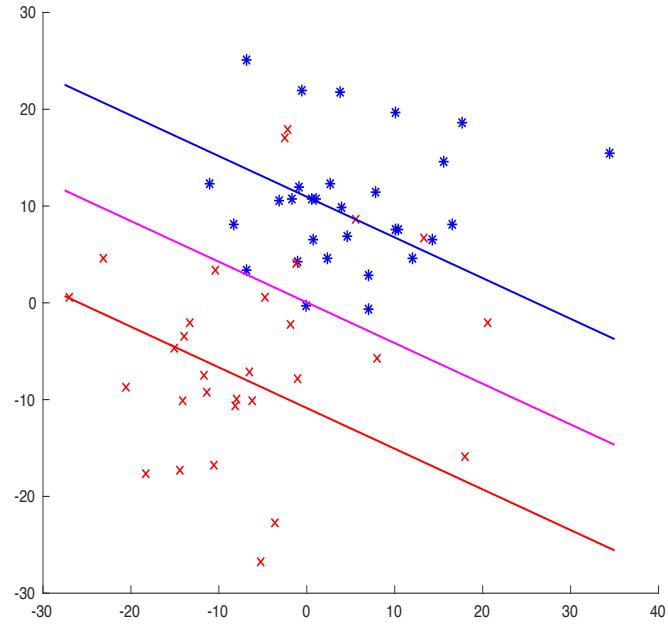

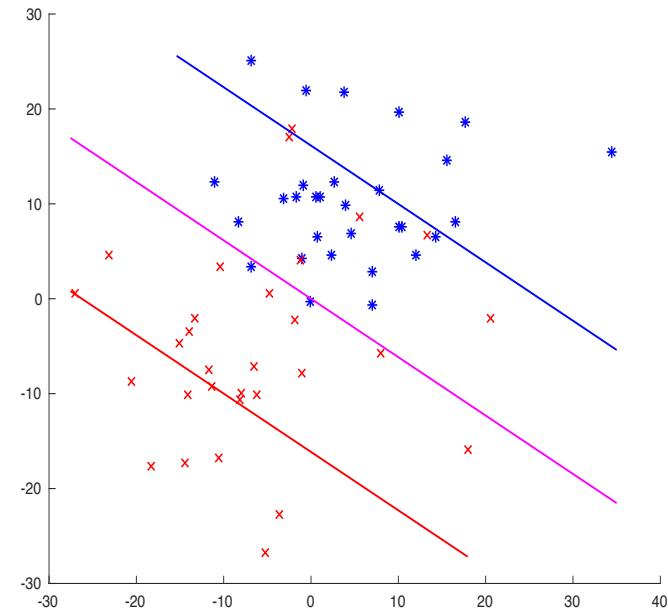

We have $p_f = 10, q_f = 10, p_m = 12$ and $q_m = 11$, as opposed to $p_f = 10, q_f = 11, p_m = 12, q_m = 12$, which was obtained by running $(\text{SVM}_{s2'})$; see Figure 54.11. A slightly narrower margin is achieved.

Next we ran our program with $\nu = 0.5$, see Figure 54.17. We have $p_f = 13, q_f = 16, p_m = 14$ and $q_m = 17$.

We also ran our program with $\nu = 0.71$, see Figure 54.18. We have $p_f = 21, q_f = 21, p_m = 22$ and $q_m = 22$. The value $\nu = 0.7$ is a singular value for which there are no support vectors and $\nu = (p_f + q_f)/(p + q)$.

Finally we ran our program with $\nu = 0.98$, see Figure 54.19. We have $p_f = 28, q_f = 30, p_m = 29$ and $q_m = 30$.

Because the term $(1/2)b^2$ is added to the objective function to be minimized, it turns out that (SVM_{s3}) yields values of b and η that are smaller than the values returned by $(\text{SVM}_{s2'})$. This is the reason why a smaller margin width could be obtained for $\nu = 0.365$. On the other hand, (SVM_{s3}) is unable to achieve as big a margin as $(\text{SVM}_{s2'})$ for values of $\nu \geq 0.97$, because the separating line produced by (SVM_{s3}) is lower than the separating line produced by $(\text{SVM}_{s2'})$.

Figure 54.17: Running (SVM_{s3}) on two sets of 30 points; $\nu = 0.5$.Figure 54.18: Running (SVM_{s3}) on two sets of 30 points; $\nu = 0.71$.

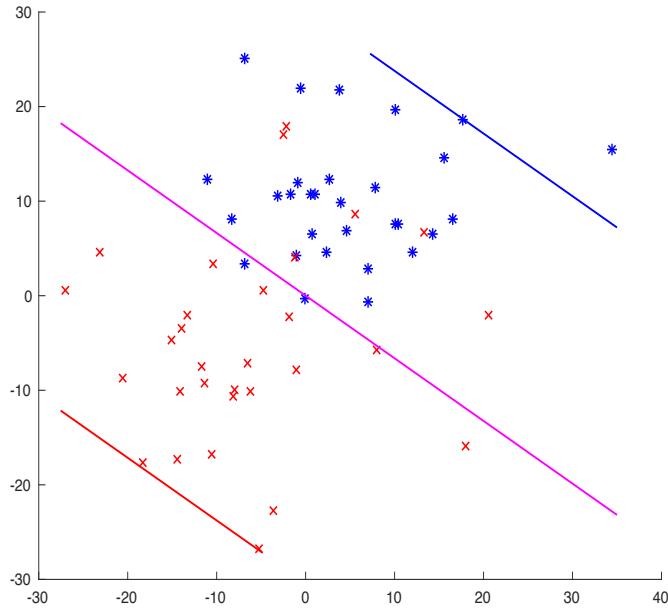

Figure 54.19: Running (SVM_{s3}) on two sets of 30 points; $\nu = 0.98$.

54.13 Soft Margin SVM; (SVM_{s4})

In this section we consider the version of Problem $(\text{SVM}_{s2'})$ in which instead of using the function $K\left(\sum_{i=1}^p \epsilon_i + \sum_{j=1}^q \xi_j\right)$ as a regularizing function we use the quadratic function $K(\|\epsilon\|_2^2 + \|\xi\|_2^2)$.

Soft margin SVM (SVM_{s4}):

$$\text{minimize } \frac{1}{2} w^\top w + (p+q)K_s \left(-\nu\eta + \frac{1}{p+q} (\epsilon^\top \epsilon + \xi^\top \xi) \right)$$

subject to

$$\begin{aligned} w^\top u_i - b &\geq \eta - \epsilon_i, & i = 1, \dots, p \\ -w^\top v_j + b &\geq \eta - \xi_j, & j = 1, \dots, q \\ \eta &\geq 0, \end{aligned}$$

where ν and K_s are two given positive constants. As we saw earlier, theoretically, it is convenient to pick $K_s = 1/(p+q)$. When writing a computer program, it is preferable to assume that K_s is arbitrary. In this case ν needs to be replaced by $(p+q)K_s\nu$ in all the formulae obtained with $K_s = 1/(p+q)$.

The new twist with this formulation of the problem is that if $\epsilon_i < 0$, then the corresponding inequality $w^\top u_i - b \geq \eta - \epsilon_i$ implies the inequality $w^\top u_i - b \geq \eta$ obtained by setting

ϵ_i to zero while reducing the value of $\|\epsilon\|^2$, and similarly if $\xi_j < 0$, then the corresponding inequality $-w^\top v_j + b \geq \eta - \xi_j$ implies the inequality $-w^\top v_j + b \geq \eta$ obtained by setting ξ_j to zero while reducing the value of $\|\xi\|^2$. Therefore, if (w, b, ϵ, ξ) is an optimal solution of Problem (SVM_{s4}), it is not necessary to restrict the slack variables ϵ_i and ξ_j to the nonnegative, which simplifies matters a bit. In fact, we will see that for an optimal solution, $\epsilon = \lambda/(2K_s)$ and $\xi = \mu/(2K_s)$. The variable η can also be determined by expressing that the duality gap is zero.

One of the advantages of this methods is that ϵ is determined by λ , ξ is determined by μ , and η and b are determined by λ and μ . This method *does not* require support vectors to compute b . We can omit the constraint $\eta \geq 0$, because for an optimal solution it can be shown using duality that $\eta \geq 0$; see Section 54.14.

A drawback of Program (SVM_{s4}) is that for fixed K_s , the quantity $\delta = \eta/\|w\|$ and the hyperplanes $H_{w,b}$, $H_{w,b+\eta}$ and $H_{w,b-\eta}$ are independent of ν . This will be shown in Theorem 54.8. Thus this method is less flexible than ($\text{SVM}_{s2'}$) and (SVM_{s3}).

The Lagrangian is given by

$$\begin{aligned} L(w, \epsilon, \xi, b, \eta, \lambda, \mu, \gamma) &= \frac{1}{2} w^\top w - \nu \eta + K_s(\epsilon^\top \epsilon + \xi^\top \xi) + w^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ &\quad - \epsilon^\top \lambda - \xi^\top \mu + b(\mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu) + \eta(\mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu) - \gamma \eta \\ &= \frac{1}{2} w^\top w + w^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + \eta(\mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu - \nu - \gamma) \\ &\quad + K_s(\epsilon^\top \epsilon + \xi^\top \xi) - \epsilon^\top \lambda - \xi^\top \mu + b(\mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu). \end{aligned}$$

To find the dual function $G(\lambda, \mu, \gamma)$ we minimize $L(w, \epsilon, \xi, b, \eta, \lambda, \mu, \gamma)$ with respect to w, ϵ, ξ, b , and η . Since the Lagrangian is convex and $(w, \epsilon, \xi, b, \eta) \in \mathbb{R}^n \times \mathbb{R}^p \times \mathbb{R}^q \times \mathbb{R} \times \mathbb{R}$, a convex open set, by Theorem 40.13, the Lagrangian has a minimum in $(w, \epsilon, \xi, b, \eta)$ iff $\nabla L_{w,\epsilon,\xi,b,\eta} = 0$, so we compute $\nabla L_{w,\epsilon,\xi,b,\eta}$. The gradient $\nabla L_{w,\epsilon,\xi,b,\eta}$ is given by

$$\nabla L_{w,\epsilon,\xi,b,\eta} = \begin{pmatrix} w + X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ 2K_s \epsilon - \lambda \\ 2K_s \xi - \mu \\ \mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu \\ \mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu - \nu - \gamma \end{pmatrix}.$$

By setting $\nabla L_{w,\epsilon,\xi,b,\eta} = 0$ we get the equations

$$\begin{aligned} w &= -X \begin{pmatrix} \lambda \\ \mu \end{pmatrix}, & (*_w) \\ 2K_s\epsilon &= \lambda \\ 2K_s\xi &= \mu \\ \mathbf{1}_p^\top \lambda &= \mathbf{1}_q^\top \mu \\ \mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu &= \nu + \gamma. \end{aligned}$$

The last two equations are identical to the last two equations obtained in Problem (SVM_{s2'}). We can use the other equations to obtain the following expression for the dual function $G(\lambda, \mu, \gamma)$,

$$\begin{aligned} G(\lambda, \mu, \gamma) &= -\frac{1}{4K_s}(\lambda^\top \lambda + \mu^\top \mu) - \frac{1}{2}(\lambda^\top \mu) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ &= -\frac{1}{2}(\lambda^\top \mu) \left(X^\top X + \frac{1}{2K_s}I_{p+q} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}. \end{aligned}$$

Consequently the dual program is equivalent to the minimization program

Dual of the Soft margin SVM (SVM_{s4}):

$$\text{minimize } \frac{1}{2}(\lambda^\top \mu) \left(X^\top X + \frac{1}{2K_s}I_{p+q} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}$$

subject to

$$\sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j = 0$$

$$\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j \geq \nu$$

$$\lambda_i \geq 0, \quad i = 1, \dots, p$$

$$\mu_j \geq 0, \quad j = 1, \dots, q.$$

The above program is similar to the program that was obtained for Problem (SVM_{s2'}) but the matrix $X^\top X$ is replaced by the matrix $X^\top X + (1/2K_s)I_{p+q}$, which is positive definite since $K_s > 0$, and also the inequalities $\lambda_i \leq K_s$ and $\mu_j \leq K_s$ no longer hold.

It is shown in Section 54.14 how the dual program is solved using ADMM from Section 52.6. If the primal problem is solvable, this yields solutions for λ and μ . We obtain w from λ and μ , as in Problem (SVM_{s2'}); namely,

$$w = -X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = \sum_{i=1}^p \lambda_i u_i - \sum_{j=1}^q \mu_j v_j.$$

Since the variables ϵ_i and ξ_j are not restricted to be nonnegative we no longer have complementary slackness conditions involving them, but we know that

$$\epsilon = \frac{\lambda}{2K_s}, \quad \xi = \frac{\mu}{2K_s}.$$

Also since the constraints

$$\sum_{i=1}^p \lambda_i \geq \frac{\nu}{2} \quad \text{and} \quad \sum_{j=1}^q \mu_j \geq \frac{\nu}{2}$$

imply that there is some i_0 such that $\lambda_{i_0} > 0$ and some j_0 such that $\mu_{j_0} > 0$, we have $\epsilon_{i_0} > 0$ and $\xi_{j_0} > 0$, which means that **at least two points are misclassified**, so Problem (SVM_{s4}) should only be used when the sets $\{u_i\}$ and $\{v_j\}$ are *not* linearly separable.

Because $\epsilon_i = \lambda_i/(2K_s)$, $\xi_j = \mu_j/(2K_s)$, and there is no upper bound K_s on λ_i and μ_j , the classification of the points is simpler than in the previous cases.

- (1) If $\lambda_i = 0$, then $\epsilon_i = 0$ and the inequality $w^\top u_i - b - \eta \geq 0$ holds. If equality holds then u_i is a support vector on the blue margin (the hyperplane $H_{w,b+\eta}$). Otherwise u_i is in the blue open half-space bounded by the margin hyperplane $H_{w,b+\eta}$ (not containing the separating hyperplane $H_{w,b}$). See Figure 54.20.

Similarly, if $\mu_j = 0$, then $\xi_j = 0$ and the inequality $-w^\top v_j + b - \eta \geq 0$ holds. If equality holds then v_j is a support vector on the red margin (the hyperplane $H_{w,b-\eta}$). Otherwise v_j is in the red open half-space bounded by the margin hyperplane $H_{w,b-\eta}$ (not containing the separating hyperplane $H_{w,b}$). See Figure 54.20.

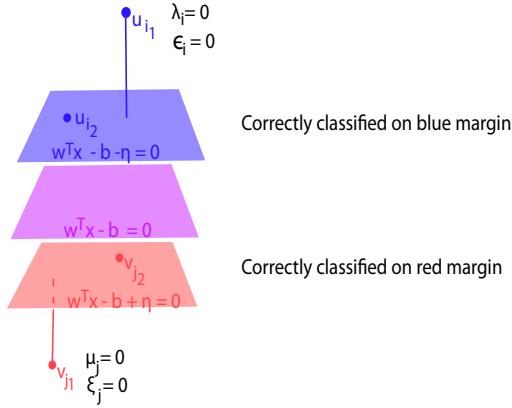

Figure 54.20: When $\lambda_i = 0$, u_i is correctly classified on or outside the blue margin. When $\mu_j = 0$, v_j is correctly classified on or outside outside the red margin.

(2) If $\lambda_i > 0$, then $\epsilon_i = \lambda_i/(2K_s) > 0$. The corresponding constraint is active, so we have

$$w^\top u_i - b = \eta - \epsilon_i.$$

If $\epsilon_i \leq \eta$, then the points u_i is inside the slab bounded by the blue margin hyperplane $H_{w,b+\eta}$ and the separating hyperplane $H_{w,b}$. If $\epsilon_i > \eta$, then the point u_i belongs to the open half-space bounded by the separating hyperplane and containing the red margin hyperplane (the red side); it is misclassified. See Figure 54.21.

Similarly, if $\mu_j > 0$, then $\xi_j = \mu_j/(2K_s) > 0$. The corresponding constraint is active, so we have

$$-w^\top v_j + b = \eta - \xi_j.$$

If $\xi_j \leq \eta$, then the points v_j is inside the slab bounded by the red margin hyperplane $H_{w,b-\eta}$ and the separating hyperplane $H_{w,b}$. If $\xi_j > \eta$, then the point v_j belongs to the open half-space bounded by the separating hyperplane and containing the blue margin hyperplane (the blue side); it is misclassified. See Figure 54.21.

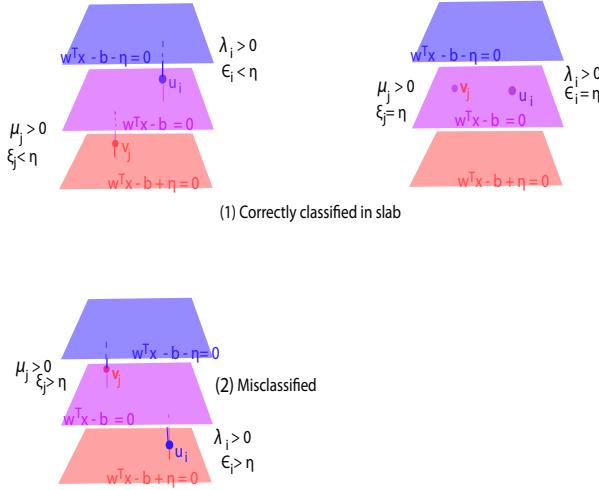

Figure 54.21: The classification of points for SVM_{s4} when the Lagrange multipliers are positive. The left illustration of Figure (1) is when u_i is inside the margin yet still on the correct side of the separating hyperplane $w^\top x - b = 0$. Similarly, v_j is inside the margin on the correct side of the separating hyperplane. The right illustration depicts u_i and v_j on the separating hyperplane. Figure (2) illustrates a misclassification of u_i and v_j .

We can use the fact that the duality gap is 0 to find η . We have

$$\frac{1}{2}w^\top w - \nu\eta + K_s(\epsilon^\top \epsilon + \xi^\top \xi) = -\frac{1}{2}(\lambda^\top \mu^\top) \left(X^\top X + \frac{1}{2K_s} I_{p+q} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix},$$

and since

$$w = -X \begin{pmatrix} \lambda \\ \mu \end{pmatrix}$$

we get

$$\begin{aligned} \nu\eta &= K_s(\epsilon^\top \epsilon + \xi^\top \xi) + (\lambda^\top \mu^\top) \left(X^\top X + \frac{1}{4K_s} I_{p+q} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ &= (\lambda^\top \mu^\top) \left(X^\top X + \frac{1}{2K_s} I_{p+q} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}. \end{aligned}$$

The above confirms that at optimality we have $\eta \geq 0$.

Remark: If we do not assume that $K_s = 1/(p+q)$, then the above formula must be replaced by

$$(p+q)K_s\nu\eta = (\lambda^\top \mu^\top) \left(X^\top X + \frac{1}{2K_s} I_{p+q} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}.$$

Since η is determined independently of the existence of support vectors, the margin hyperplane $H_{w,b+\eta}$ may not contain any point u_i and the margin hyperplane $H_{w,b-\eta}$ may not contain any point v_j .

We can solve for b using some active constraint corresponding to any i_0 such that $\lambda_{i_0} > 0$ and any j_0 such that $\mu_{j_0} > 0$ (by a previous remark, the constraints imply that such i_0 and j_0 must exist). To improve numerical stability we average over the following sets of indices. Let I_λ and I_μ be the set of indices given by

$$\begin{aligned} I_\lambda &= \{i \in \{1, \dots, p\} \mid \lambda_i > 0\} \\ I_\mu &= \{j \in \{1, \dots, q\} \mid \mu_j > 0\}, \end{aligned}$$

and let $p_m = |I_\lambda|$ and $q_m = |I_\mu|$. We obtain the formula

$$b = \left(w^\top \left(\left(\sum_{i \in I_\lambda} u_i \right) / p_m + \left(\sum_{j \in I_\mu} v_j \right) / q_m \right) + \left(\sum_{i \in I_\lambda} \epsilon_i \right) / p_m - \left(\sum_{j \in I_\mu} \xi_j \right) / q_m \right) / 2.$$

We now prove that for a fixed K_s , the solution to Problem (SVM_{s4}) is unique and independent of the value of ν .

Theorem 54.8. *For K_s and ν fixed, if Problem (SVM_{s4}) succeeds, then it has a unique solution. If Problem (SVM_{s4}) succeeds and returns $(\lambda, \mu, \eta, w, b)$ for the value ν and $(\lambda^\kappa, \mu^\kappa, \eta^\kappa, w^\kappa, b^\kappa)$ for the value $\kappa\nu$ with $\kappa > 0$, then*

$$\lambda^\kappa = \kappa\lambda, \quad \mu^\kappa = \kappa\mu, \quad \eta^\kappa = \kappa\eta, \quad w^\kappa = \kappa w, \quad b^\kappa = \kappa b.$$

As a consequence, $\delta = \eta / \|w\| = \eta^\kappa / \|w^\kappa\| = \delta^\kappa$, and the hyperplanes $H_{w,b}$, $H_{w,b+\eta}$ and $H_{w,b-\eta}$ are independent of ν .

Proof. We already observed that for an optimal solution with $\eta > 0$, we have $\gamma = 0$. This means that (λ, μ) is a solution of the problem

$$\text{minimize} \quad \frac{1}{2} (\lambda^\top \quad \mu^\top) \left(X^\top X + \frac{1}{2K_s} I_{p+q} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}$$

subject to

$$\sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j = 0$$

$$\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j = \nu$$

$$\lambda_i \geq 0, \quad i = 1, \dots, p$$

$$\mu_j \geq 0, \quad j = 1, \dots, q.$$

Since $K_s > 0$ and $X^\top X$ is symmetric positive semidefinite, the matrix

$P = X^\top X + \frac{1}{2K_s} I_{p+q}$ is symmetric positive definite. Let $\Omega = \mathbb{R}^{p+q}$ and let U be the convex set given by

$$U = \left\{ \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \in \mathbb{R}_+^{p+q} \mid \begin{pmatrix} \mathbf{1}_p^\top & -\mathbf{1}_q^\top \\ \mathbf{1}_p^\top & \mathbf{1}_q^\top \end{pmatrix} \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = \begin{pmatrix} 0 \\ (p+q)K_s\nu \end{pmatrix} \right\}.$$

Since the matrix P is symmetric positive definite, the functional

$$F(\lambda, \mu) = -G(\lambda, \mu) = \frac{1}{2} (\lambda^\top \quad \mu^\top) P \begin{pmatrix} \lambda \\ \mu \end{pmatrix}$$

is strictly convex and U is convex, so by Theorem 40.13(2,4), if it has a minimum, then it is unique. Consider the convex set

$$U^\kappa = \left\{ \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \in \mathbb{R}_+^{p+q} \mid \begin{pmatrix} \mathbf{1}_p^\top & -\mathbf{1}_q^\top \\ \mathbf{1}_p^\top & \mathbf{1}_q^\top \end{pmatrix} \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = \begin{pmatrix} 0 \\ (p+q)K_s\kappa\nu \end{pmatrix} \right\}.$$

Observe that

$$\kappa U = \left\{ \begin{pmatrix} \kappa\lambda \\ \kappa\mu \end{pmatrix} \in \mathbb{R}_+^{p+q} \mid \begin{pmatrix} \mathbf{1}_p^\top & -\mathbf{1}_q^\top \\ \mathbf{1}_p^\top & \mathbf{1}_q^\top \end{pmatrix} \begin{pmatrix} \kappa\lambda \\ \kappa\mu \end{pmatrix} = \begin{pmatrix} 0 \\ (p+q)K_s\kappa\nu \end{pmatrix} \right\} = U^\kappa.$$

By Theorem 40.13(3), $(\lambda, \mu) \in U$ is a minimum of F over U iff

$$dF_{\lambda, \mu} \begin{pmatrix} \lambda' - \lambda \\ \mu' - \mu \end{pmatrix} \geq 0 \quad \text{for all } \begin{pmatrix} \lambda' \\ \mu' \end{pmatrix} \in U.$$

Since

$$dF_{\lambda, \mu} \begin{pmatrix} \lambda' - \lambda \\ \mu' - \mu \end{pmatrix} = (\lambda^\top \quad \mu^\top) P \begin{pmatrix} \lambda' - \lambda \\ \mu' - \mu \end{pmatrix}$$

the above conditions are equivalent to

$$\begin{aligned} (\lambda^\top \quad \mu^\top) P \begin{pmatrix} \lambda' - \lambda \\ \mu' - \mu \end{pmatrix} &\geq 0 \\ \begin{pmatrix} \mathbf{1}_p^\top & -\mathbf{1}_q^\top \\ \mathbf{1}_p^\top & \mathbf{1}_q^\top \end{pmatrix} \begin{pmatrix} \lambda \\ \mu \end{pmatrix} &= \begin{pmatrix} 0 \\ (p+q)K_s\nu \end{pmatrix} \\ \lambda, \lambda' \in \mathbb{R}_+^p, \mu, \mu' \in \mathbb{R}_+^q. \end{aligned}$$

Since $\kappa > 0$, by multiplying the above inequality by κ^2 and the equations by κ , the following conditions hold:

$$\begin{aligned} (\kappa\lambda^\top \quad \kappa\mu^\top) P \begin{pmatrix} \kappa\lambda' - \kappa\lambda \\ \kappa\mu' - \kappa\mu \end{pmatrix} &\geq 0 \\ \begin{pmatrix} \mathbf{1}_p^\top & -\mathbf{1}_q^\top \\ \mathbf{1}_p^\top & \mathbf{1}_q^\top \end{pmatrix} \begin{pmatrix} \kappa\lambda \\ \kappa\mu \end{pmatrix} &= \begin{pmatrix} 0 \\ (p+q)K_s\kappa\nu \end{pmatrix} \\ \kappa\lambda, \kappa\lambda' \in \mathbb{R}_+^p, \kappa\mu, \kappa\mu' \in \mathbb{R}_+^q. \end{aligned}$$

By Theorem 40.13(3), $(\kappa\lambda, \kappa\mu) \in U^\kappa$ is a minimum of F over U^κ , and because F is strictly convex and U^κ is convex, if F has a minimum over U^κ , then $(\kappa\lambda, \kappa\mu) \in U^\kappa$ is the unique minimum. Therefore, $\lambda^\kappa = \kappa\lambda$, $\mu^\kappa = \kappa\mu$.

Since w is given by the equation

$$w = -X \begin{pmatrix} \lambda \\ \mu \end{pmatrix}$$

and since we just showed that $\lambda^\kappa = \kappa\lambda$, $\mu^\kappa = \kappa\mu$, we deduce that $w^\kappa = \kappa w$.

We showed earlier that η is given by the equation

$$(p+q)K_s\nu\eta = (\lambda^\top \quad \mu^\top) \left(X^\top X + \frac{1}{2K_s} I_{p+q} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}.$$

If we replace ν by $\kappa\nu$, since λ is replaced by $\kappa\lambda$ and μ by $\kappa\mu$, we see that $\eta^\kappa = \kappa\eta$. Finally, b is given by the equation

$$b = \frac{w^\top(u_{i_0} + v_{j_0}) + \epsilon_{i_0} - \xi_{j_0}}{2}$$

for and i_0 such that $\lambda_{i_0} > 0$ and any j_0 such that $\mu_{j_0} > 0$. If λ is replaced by $\kappa\lambda$ and μ by $\kappa\mu$, since $\epsilon = \lambda/(2K_s)$ and $\xi = \mu/(2K_s)$, we see that ϵ is replaced by $\kappa\epsilon$ and ξ by $\kappa\xi$, so $b^\kappa = \kappa b$.

Since $w^\kappa = \kappa w$ and $\eta^\kappa = \kappa\eta$ we obtain $\delta = \eta/\|w\| = \eta^\kappa/\|w^\kappa\| = \delta^\kappa$. Since $w^\kappa = \kappa w$, $\eta^\kappa = \kappa\eta$ and $b^\kappa = \kappa b$, the normalized equations of the hyperplanes $H_{w,b}$, $H_{w,b+\eta}$ and $H_{w,b-\eta}$ (obtained by dividing by $\|w\|$) are all identical, so the hyperplanes $H_{w,b}$, $H_{w,b+\eta}$ and $H_{w,b-\eta}$ are independent of ν . \square

The width of the slab is controlled by K . The larger K is the smaller is the width of the slab. Theoretically, since this method does not rely on support vectors to compute b , it cannot fail if a solution exists, but in practice the quadratic solver does not converge for values of K that are too large. However, the method handles very small values of K , which can yield slabs of excessive width.

The “kernelized” version of Problem (SVM_{s4}) is the following:

Soft margin kernel SVM (SVM_{s4}):

$$\begin{aligned} & \text{minimize} \quad \frac{1}{2} \langle w, w \rangle - \nu \eta + K_s (\epsilon^\top \epsilon + \xi^\top \xi) \\ & \text{subject to} \\ & \quad \langle w, \varphi(u_i) \rangle - b \geq \eta - \epsilon_i, \quad i = 1, \dots, p \\ & \quad -\langle w, \varphi(v_j) \rangle + b \geq \eta - \xi_j, \quad j = 1, \dots, q \\ & \quad \eta \geq 0, \end{aligned}$$

with $K_s = 1/(p+q)$.

By going over the derivation of the dual program, we obtain

Dual of the Soft margin kernel SVM (SVM_{s4}):

$$\begin{aligned} & \text{minimize} \quad \frac{1}{2} (\lambda^\top \mu^\top) \left(\mathbf{K} + \frac{1}{2K_s} I_{p+q} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ & \text{subject to} \\ & \quad \sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j = 0 \\ & \quad \sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j \geq \nu \\ & \quad \lambda_i \geq 0, \quad i = 1, \dots, p \\ & \quad \mu_j \geq 0, \quad j = 1, \dots, q, \end{aligned}$$

where \mathbf{K} is the kernel matrix of Section 54.1. Then w , b , and $f(x)$ are obtained exactly as in Section 54.5.

54.14 Solving SVM (SVM_{s4}) Using ADMM

In order to solve (SVM_{s4}) using ADMM we need to write the matrix corresponding to the constraints in equational form,

$$\begin{aligned} \sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j &= 0 \\ \sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j - \gamma &= K_m, \end{aligned}$$

with $K_m = (p+q)K_s\nu$. This is the $2 \times (p+q+1)$ matrix A given by

$$A = \begin{pmatrix} \mathbf{1}_p^\top & -\mathbf{1}_q^\top & 0 \\ \mathbf{1}_p^\top & \mathbf{1}_q^\top & -1 \end{pmatrix}.$$

We leave it as an exercise to prove that A has rank 2. The right-hand side is

$$c = \begin{pmatrix} 0 \\ K_m \end{pmatrix}.$$

The symmetric positive semidefinite $(p+q) \times (p+q)$ matrix P defining the quadratic functional is

$$P = X^\top X + \frac{1}{2K_s} I_{p+q}, \quad \text{with } X = \begin{pmatrix} -u_1 & \cdots & -u_p & v_1 & \cdots & v_q \end{pmatrix},$$

and

$$q = 0_{p+q}.$$

Since there are $p+q+1$ Lagrange multipliers (λ, μ, γ) , the $(p+q) \times (p+q)$ matrix P must be augmented with zero's to make it a $(p+q+1) \times (p+q+1)$ matrix P_a given by

$$P_a = \begin{pmatrix} X^\top X & 0_{p+q} \\ 0_{p+q}^\top & 0 \end{pmatrix},$$

and similarly q is augmented with zeros as the vector $q_a = 0_{p+q+1}$.

As in Section 54.8, since $\eta \geq 0$ for an optimal solution, we can drop the constraint $\eta \geq 0$ from the primal problem. In this case, there are $p+q$ Lagrange multipliers (λ, μ) . It is easy to see that the objective function of the dual is unchanged and the set of constraints is

$$\begin{aligned} \sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j &= 0 \\ \sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j &= K_m, \end{aligned}$$

with $K_m = (p+q)K_s\nu$. The matrix corresponding to the above equations is the $2 \times (p+q)$ matrix A_2 given by

$$A_2 = \begin{pmatrix} \mathbf{1}_p^\top & -\mathbf{1}_q^\top \\ \mathbf{1}_p^\top & \mathbf{1}_q^\top \end{pmatrix}.$$

We leave it as an exercise to prove that A_2 has rank 2. The right-hand side is

$$c_2 = \begin{pmatrix} 0 \\ K_m \end{pmatrix}.$$

The symmetric positive semidefinite $(p+q) \times (p+q)$ matrix P defining the quadratic functional is

$$P = X^\top X + \frac{1}{2K_s} I_{p+q}, \quad \text{with } X = \begin{pmatrix} -u_1 & \cdots & -u_p & v_1 & \cdots & v_q \end{pmatrix},$$

and

$$q = 0_{p+q}.$$

Since there are $p+q$ Lagrange multipliers (λ, μ) , the $(p+q) \times (p+q)$ matrix P need not be augmented with zero's, so $P_{2a} = P$ and similarly $q_{2a} = 0_{p+q}$.

We ran our **Matlab** implementation of the above version of (SVM_{s4}) on the data set of Section 54.12. Since the value of ν is irrelevant, we picked $\nu = 1$. First we ran our program with $K = 190$; see Figure 54.22. We have $p_m = 23$ and $q_m = 18$. The program does not converge for $K \geq 200$.

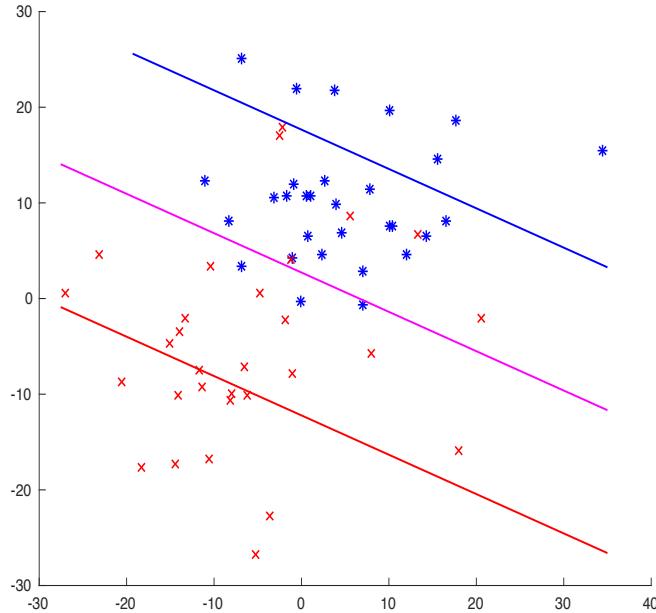

Figure 54.22: Running (SVM_{s4}) on two sets of 30 points; $K = 190$.

Our second run was made with $K = 1/12000$; see Figure 54.23. We have $p_m = 30$ and $q_m = 30$ and we see that the width of the slab is a bit excessive. This example demonstrates that the margin lines need not contain data points.

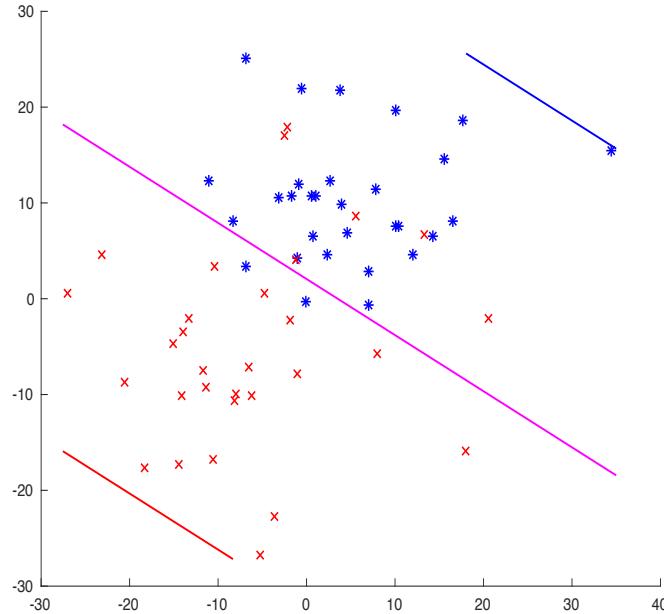

Figure 54.23: Running (SVM_{s4}) on two sets of 30 points; $K = 1/12000$.

54.15 Soft Margin SVM; (SVM_{s5})

In this section we consider the version of Problem (SVM_{s4}) in which we add the term $(1/2)b^2$ to the objective function. We also drop the constraint $\eta \geq 0$ which is redundant.

Soft margin SVM (SVM_{s5}):

$$\text{minimize} \quad \frac{1}{2}w^\top w + \frac{1}{2}b^2 + (p+q)K_s \left(-\nu\eta + \frac{1}{p+q}(\epsilon^\top \epsilon + \xi^\top \xi) \right)$$

subject to

$$\begin{aligned} w^\top u_i - b &\geq \eta - \epsilon_i, & i = 1, \dots, p \\ -w^\top v_j + b &\geq \eta - \xi_j, & j = 1, \dots, q, \end{aligned}$$

where ν and K_s are two given positive constants. As we saw earlier, it is convenient to pick $K_s = 1/(p+q)$. When writing a computer program, it is preferable to assume that K_s is arbitrary. In this case ν must be replaced by $(p+q)K_s\nu$ in all the formulae.

One of the advantages of this methods is that ϵ is determined by λ , ξ is determined by μ (as in (SVM_{s4})), and both η and b determined by λ and μ . As the previous method, this method *does not* require support vectors to compute b . We can omit the constraint $\eta \geq 0$, because for an optimal solution it can be shown using duality that $\eta \geq 0$.

A drawback of Program (SVM_{s5}) is that for fixed K_s , the quantity $\delta = \eta / \|w\|$ and the hyperplanes $H_{w,b}$, $H_{w,b+\eta}$ and $H_{w,b-\eta}$ are independent of ν . This will be shown in Theorem 54.9. Thus this method is less flexible than $(\text{SVM}_{s2'})$ and (SVM_{s3}) .

The Lagrangian is given by

$$\begin{aligned} L(w, \epsilon, \xi, b, \eta, \lambda, \mu) &= \frac{1}{2} w^\top w + \frac{1}{2} b^2 - \nu \eta + K_s(\epsilon^\top \epsilon + \xi^\top \xi) + w^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ &\quad - \epsilon^\top \lambda - \xi^\top \mu + b(\mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu) + \eta(\mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu) \\ &= \frac{1}{2} w^\top w + w^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + \eta(\mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu - \nu) \\ &\quad + K_s(\epsilon^\top \epsilon + \xi^\top \xi) - \epsilon^\top \lambda - \xi^\top \mu + b(\mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu) + \frac{1}{2} b^2. \end{aligned}$$

To find the dual function $G(\lambda, \mu)$ we minimize $L(w, \epsilon, \xi, b, \eta, \lambda, \mu)$ with respect to w, ϵ, ξ, b , and η . Since the Lagrangian is convex and $(w, \epsilon, \xi, b, \eta) \in \mathbb{R}^n \times \mathbb{R}^p \times \mathbb{R}^q \times \mathbb{R} \times \mathbb{R}$, a convex open set, by Theorem 40.13, the Lagrangian has a minimum in $(w, \epsilon, \xi, b, \eta)$ iff $\nabla L_{w,\epsilon,\xi,b,\eta} = 0$, so we compute $\nabla L_{w,\epsilon,\xi,b,\eta}$. The gradient $\nabla L_{w,\epsilon,\xi,b,\eta}$ is given by

$$\nabla L_{w,\epsilon,\xi,b,\eta} = \begin{pmatrix} w + X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ 2K_s \epsilon - \lambda \\ 2K_s \xi - \mu \\ b + \mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu \\ \mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu - \nu \end{pmatrix}.$$

By setting $\nabla L_{w,\epsilon,\xi,b,\eta} = 0$ we get the equations

$$\begin{aligned} w &= -X \begin{pmatrix} \lambda \\ \mu \end{pmatrix}, & (*_w) \\ 2K_s \epsilon &= \lambda \\ 2K_s \xi &= \mu \\ b &= -(\mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu) \\ \mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu &= \nu. \end{aligned}$$

As we said earlier, both w and b are determined by λ and μ . We can use the equations to

obtain the following expression for the dual function $G(\lambda, \mu, \gamma)$,

$$\begin{aligned} G(\lambda, \mu, \gamma) &= -\frac{1}{4K_s}(\lambda^\top \lambda + \mu^\top \mu) - \frac{1}{2} (\lambda^\top \mu) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - \frac{b^2}{2} \\ &= -\frac{1}{2} (\lambda^\top \mu) \left(X^\top X + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix} + \frac{1}{2K_s} I_{p+q} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}. \end{aligned}$$

Consequently the dual program is equivalent to the minimization program

Dual of the Soft margin SVM (SVM_{s5}):

$$\begin{aligned} \text{minimize } & \frac{1}{2} (\lambda^\top \mu) \left(X^\top X + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix} + \frac{1}{2K_s} I_{p+q} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ \text{subject to } & \end{aligned}$$

$$\begin{aligned} & \sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j = \nu \\ & \lambda_i \geq 0, \quad i = 1, \dots, p \\ & \mu_j \geq 0, \quad j = 1, \dots, q. \end{aligned}$$

It is shown in Section 54.16 how the dual program is solved using ADMM from Section 52.6. If the primal problem is solvable, this yields solutions for λ and μ .

The constraint

$$\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j = \nu$$

implies that either there is some i_0 such that $\lambda_{i_0} > 0$ or there is some j_0 such that $\mu_{j_0} > 0$, so we have $\epsilon_{i_0} > 0$ or $\xi_{j_0} > 0$, which means that **at least one point is misclassified**. Thus Problem (SVM_{s5}) should only be used when the sets $\{u_i\}$ and $\{v_j\}$ are *not* linearly separable.

We can use the fact that the duality gap is 0 to find η . We have

$$\begin{aligned} & \frac{1}{2} w^\top w + \frac{b^2}{2} - \nu \eta + K_s(\epsilon^\top \epsilon + \xi^\top \xi) \\ &= -\frac{1}{2} (\lambda^\top \mu) \left(X^\top X + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix} + \frac{1}{2K_s} I_{p+q} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}, \end{aligned}$$

so we get

$$\begin{aligned} \nu \eta &= K_s(\epsilon^\top \epsilon + \xi^\top \xi) + (\lambda^\top \mu) \left(X^\top X + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix} + \frac{1}{4K_s} I_{p+q} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ &= (\lambda^\top \mu) \left(X^\top X + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix} + \frac{1}{2K_s} I_{p+q} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}. \end{aligned}$$

The above confirms that at optimality we have $\eta \geq 0$.

Remark: If we do not assume that $K_s = 1/(p+q)$, then the above formula must be replaced by

$$(p+q)K_s\nu\eta = (\lambda^\top \ \mu^\top) \begin{pmatrix} X^\top X + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix} + \frac{1}{2K_s} I_{p+q} \end{pmatrix} \begin{pmatrix} \lambda \\ \mu \end{pmatrix}.$$

There is a version of Theorem 54.8 stating that for a fixed K_s , the solution to Problem (SVM_{s5}) is unique and independent of the value of ν .

Theorem 54.9. *For K_s and ν fixed, if Problem (SVM_{s5}) succeeds then it has a unique solution. If Problem (SVM_{s5}) succeeds and returns $(\lambda, \mu, \eta, w, b)$ for the value ν and $(\lambda^\kappa, \mu^\kappa, \eta^\kappa, w^\kappa, b^\kappa)$ for the value $\kappa\nu$ with $\kappa > 0$, then*

$$\lambda^\kappa = \kappa\lambda, \ \mu^\kappa = \kappa\mu, \ \eta^\kappa = \kappa\eta, \ w^\kappa = \kappa w, \ b^\kappa = \kappa b.$$

As a consequence, $\delta = \eta/\|w\| = \eta^\kappa/\|w^\kappa\| = \delta^\kappa$, and the hyperplanes $H_{w,b}$, $H_{w,b+\eta}$ and $H_{w,b-\eta}$ are independent of ν .

Proof. The proof is an easy adaptation of the proof of Theorem 54.8 so we only give a sketch. The two crucial points are that the matrix

$$P = X^\top X + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix} + \frac{1}{2K_s} I_{p+q}$$

is symmetric positive definite and that we have the single equational constraint

$$\mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu = (p+q)K_s\nu$$

defining the convex set

$$U = \left\{ \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \in \mathbb{R}_+^{p+q} \mid \mathbf{1}_p^\top \lambda + \mathbf{1}_q^\top \mu = (p+q)K_s\nu \right\}.$$

The proof is essentially the proof of 54.8 using the above SPD matrix and convex set. \square

The “kernelized” version of Problem (SVM_{s5}) is the following:

Soft margin kernel SVM (SVM_{s5}):

$$\text{minimize} \quad \frac{1}{2} \langle w, w \rangle + \frac{1}{2} b^2 - \nu\eta + K_s(\epsilon^\top \epsilon + \xi^\top \xi)$$

subject to

$$\begin{aligned} \langle w, \varphi(u_i) \rangle - b &\geq \eta - \epsilon_i, & i = 1, \dots, p \\ -\langle w, \varphi(v_j) \rangle + b &\geq \eta - \xi_j, & j = 1, \dots, q, \end{aligned}$$

with $K_s = 1/(p+q)$.

Tracing through the derivation of the dual program, we obtain

Dual of the Soft margin kernel SVM (SVM_{s5}):

$$\begin{aligned} \text{minimize} \quad & \frac{1}{2} (\lambda^\top - \mu^\top) \left(\mathbf{K} + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix} + \frac{1}{2K_s} I_{p+q} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ \text{subject to} \quad & \end{aligned}$$

$$\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j = \nu$$

$$\lambda_i \geq 0, \quad i = 1, \dots, p$$

$$\mu_j \geq 0, \quad j = 1, \dots, q,$$

where \mathbf{K} is the kernel matrix of Section 54.1. Then w , b , and $f(x)$ are obtained exactly as in Section 54.13.

54.16 Solving SVM (SVM_{s5}) Using ADMM

In order to solve (SVM_5) using ADMM we need to write the matrix corresponding to the constraints in equational form,

$$\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j = K_m,$$

with $K_m = (p+q)K_s\nu$. This is the $1 \times (p+q)$ matrix A given by

$$A = (\mathbf{1}_p^\top \quad \mathbf{1}_q^\top).$$

Obviously, A has rank 1. The right-hand side is

$$c = K_m.$$

The symmetric positive definite $(p+q) \times (p+q)$ matrix P defining the quadratic functional is

$$P = X^\top X + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix} + \frac{1}{2K_s} I_{p+q}, \quad \text{with } X = (-u_1 \quad \cdots \quad -u_p \quad v_1 \quad \cdots \quad v_q),$$

and

$$q = 0_{p+q}.$$

Since there are $p+q$ Lagrange multipliers (λ, μ) , the $(p+q) \times (p+q)$ matrix P does not have to be augmented with zero's.

We ran our Matlab implementation of the above version of (SVM_{s5}) on the data set of Section 54.14. Since the value of ν is irrelevant, we picked $\nu = 1$. First we ran our program

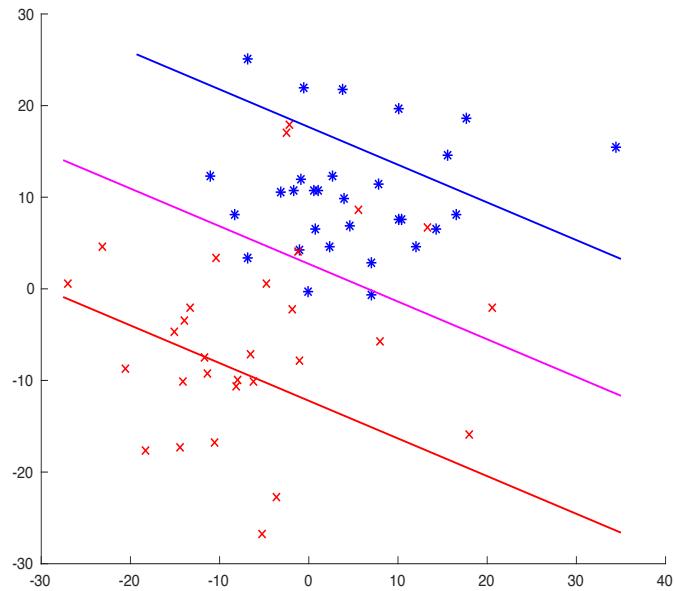

Figure 54.24: Running (SVM_{s5}) on two sets of 30 points; $K = 190$.

with $K = 190$; see Figure 54.24. We have $p_m = 23$ and $q_m = 18$. The program does not converge for $K \geq 200$.

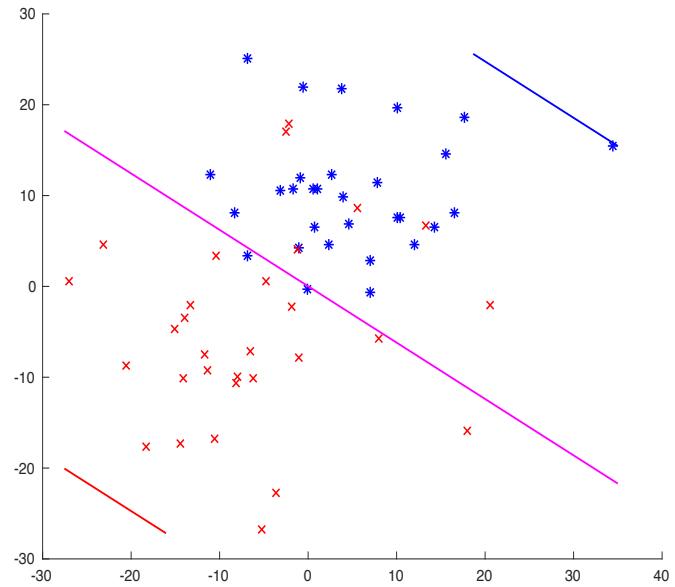

Figure 54.25: Running (SVM_{s5}) on two sets of 30 points; $K = 1/13000$.

Our second run was made with $K = 1/13000$; see Figure 54.25. We have $p_m = 30$ and $q_m = 30$ and we see that the width of the slab is a bit excessive. This example demonstrates that the margin lines need not contain data points.

Method (SVM_{s5}) always returns a value for b and η smaller than the value returned by (SVM_{s4}) (because of the term $(1/2)b^2$ added to the objective function) but in this example the difference is too small to be noticed.

54.17 Summary and Comparison of the SVM Methods

In this chapter we considered six variants for solving the soft margin binary classification problem for two sets of points $\{u_i\}_{i=1}^p$ and $\{v_j\}_{j=1}^q$ using support vector classification methods. The objective is to find a separating hyperplane $H_{w,b}$ of equation $w^\top x - b = 0$. We also try to find two “margin hyperplanes” $H_{w,b+\delta}$ of equation $w^\top x - b - \delta = 0$ (the blue margin hyperplane) and $H_{w,b-\delta}$ of equation $w^\top x - b + \delta = 0$ (the red margin hyperplane) such that δ is as big as possible and yet the number of misclassified points is minimized, which is achieved by allowing an error $\epsilon_i \geq 0$ for every point u_i , in the sense that the constraint

$$w^\top u_i - b \geq \delta - \epsilon_i$$

should hold, and an error $\xi_j \geq 0$ for every point v_j , in the sense that the constraint

$$-w^\top v_j + b \geq \delta - \xi_j$$

should hold.

The goal is to design an objective function that minimizes ϵ and ξ and maximizes δ . The optimization problem should also solve for w and b , and for this some constraint has to be placed on w . Another goal is to try to use the dual program to solve the optimization problem, because the solutions involve inner products, and thus the problem is amenable to a generalization using kernel functions.

The first attempt, which is to use the objective function

$$J(w, \epsilon, \xi, b, \delta) = -\delta + K(\epsilon^\top \xi^\top) \mathbf{1}_{p+q}$$

and the constraint $w^\top w \leq 1$, does not work very well because this constraint needs to be guarded by a Lagrange multiplier $\gamma \geq 0$, and as a result, minimizing the Lagrangian L to find the dual function G gives an equation for solving w of the form

$$2\gamma w = -X^\top \begin{pmatrix} \lambda \\ \mu \end{pmatrix},$$

but if the sets $\{u_i\}_{i=1}^p$ and $\{v_j\}_{j=1}^q$ are not linearly separable, then an optimal solution may occurs for $\gamma = 0$, in which case it is impossible to determine w . This is Problem (SVM_{s1}) considered in Section 54.1.

Soft margin SVM (SVM_{s1}):

$$\text{minimize} \quad -\delta + K \left(\sum_{i=1}^p \epsilon_i + \sum_{j=1}^q \xi_j \right)$$

subject to

$$\begin{aligned} w^\top u_i - b &\geq \delta - \epsilon_i, \quad \epsilon_i \geq 0 \quad i = 1, \dots, p \\ -w^\top v_j + b &\geq \delta - \xi_j, \quad \xi_j \geq 0 \quad j = 1, \dots, q \\ w^\top w &\leq 1. \end{aligned}$$

It is customary to write $\ell = p + q$.

It is shown in Section 54.1 that the dual program is equivalent to the following minimization program:

Dual of the Soft margin SVM (SVM_{s1}):

$$\text{minimize} \quad (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix}$$

subject to

$$\begin{aligned} \sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j &= 0 \\ \sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j &= 1 \\ 0 \leq \lambda_i &\leq K, \quad i = 1, \dots, p \\ 0 \leq \mu_j &\leq K, \quad j = 1, \dots, q. \end{aligned}$$

The points u_i and v_j are naturally classified in terms of the values of λ_i and μ_j . The numbers of points in each category have a direct influence on the choice of the parameter K . Let us summarize some of the keys items from Definition 54.1.

The vectors u_i on the blue margin $H_{w,b+\delta}$ and the vectors v_j on the red margin $H_{w,b-\delta}$ are called *support vectors*. Support vectors correspond to vectors u_i for which $w^\top u_i - b - \delta = 0$ (which implies $\epsilon_i = 0$), and vectors v_j for which $w^\top v_j - b + \delta = 0$ (which implies $\xi_j = 0$). Support vectors u_i such that $0 < \lambda_i < K$ and support vectors v_j such that $0 < \mu_j < K$ are *support vectors of type 1*. Support vectors of type 1 play a special role so we denote the sets of indices associated with them by

$$\begin{aligned} I_\lambda &= \{i \in \{1, \dots, p\} \mid 0 < \lambda_i < K\} \\ I_\mu &= \{j \in \{1, \dots, q\} \mid 0 < \mu_j < K\}. \end{aligned}$$

We denote their cardinalities by $\text{numsvl}_1 = |I_\lambda|$ and $\text{numsvm}_1 = |I_\mu|$.

The vectors u_i for which $\lambda_i = K$ and the vectors v_j for which $\mu_j = K$ are said to *fail the margin*. The sets of indices associated with the vectors failing the margin are denoted by

$$\begin{aligned} K_\lambda &= \{i \in \{1, \dots, p\} \mid \lambda_i = K\} \\ K_\mu &= \{j \in \{1, \dots, q\} \mid \mu_j = K\}. \end{aligned}$$

We denote their cardinalities by $p_f = |K_\lambda|$ and $q_f = |K_\mu|$.

Vectors u_i such that $\lambda_i > 0$ and vectors v_j such that $\mu_j > 0$ are said to *have margin at most δ* . The sets of indices associated with these vectors are denoted by

$$\begin{aligned} I_{\lambda>0} &= \{i \in \{1, \dots, p\} \mid \lambda_i > 0\} \\ I_{\mu>0} &= \{j \in \{1, \dots, q\} \mid \mu_j > 0\}. \end{aligned}$$

We denote their cardinalities by $p_m = |I_{\lambda>0}|$ and $q_m = |I_{\mu>0}|$.

Obviously, $p_f \leq p_m$ and $q_f \leq q_m$. There are $p - p_m$ points u_i classified correctly on the blue side and outside the δ -slab and there are $q - q_m$ points v_j classified correctly on the red side and outside the δ -slab. Intuitively a blue point that fails the margin is on the wrong side of the blue margin and a red point that fails the margin is on the wrong side of the red margin.

It can be shown that that K must be chosen so that

$$\max \left\{ \frac{1}{2p_m}, \frac{1}{2q_m} \right\} \leq K \leq \min \left\{ \frac{1}{2p_f}, \frac{1}{2q_f} \right\}.$$

If the optimal value is 0, then $\gamma = 0$ and $X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = 0$, so in this case it is not possible to determine w . However, if the optimal value is > 0 , then once a solution for λ and μ is obtained, we have

$$\begin{aligned} \gamma &= \frac{1}{2} \left((\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \right)^{1/2} \\ w &= \frac{1}{2\gamma} \left(\sum_{i=1}^p \lambda_i u_i - \sum_{j=1}^q \mu_j v_j \right), \end{aligned}$$

so we get

$$w = \frac{\sum_{i=1}^p \lambda_i u_i - \sum_{j=1}^q \mu_j v_j}{\left((\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \right)^{1/2}},$$

If the following mild hypothesis holds, then b and δ can be found.

Standard Margin Hypothesis for (SVM_{s1}) . There is some index i_0 such that $0 < \lambda_{i_0} < K$ and there is some index j_0 such that $0 < \mu_{j_0} < K$. This means that some u_{i_0} is a support vector of type 1 on the blue margin, and some v_{j_0} is a support vector of type 1 on the red margin.

If the **Standard Margin Hypothesis** for (SVM_{s1}) holds, then $\epsilon_{i_0} = 0$ and $\mu_{j_0} = 0$, and we have the active equations

$$w^\top u_{i_0} - b = \delta \quad \text{and} \quad -w^\top v_{j_0} + b = \delta,$$

and we obtain the value of b and δ as

$$\begin{aligned} b &= \frac{1}{2} w^\top (u_{i_0} + v_{j_0}) \\ \delta &= \frac{1}{2} w^\top (u_{i_0} - v_{j_0}). \end{aligned}$$

The second more successful approach is to add the term $(1/2)w^\top w$ to the objective function and to drop the constraint $w^\top w \leq 1$. There are several variants of this method, depending on the choice of the regularizing term involving ϵ and ξ (linear or quadratic), how the margin is dealt with (implicitly with the term 1 or explicitly with a term η), and whether the term $(1/2)b^2$ is added to the objective function or not.

These methods all share the property that if the primal problem has an optimal solution with $w \neq 0$, then the dual problem always determines w , and then under mild conditions which we call standard margin hypotheses, b and η can be determined. Then ϵ and ξ can be determined using the constraints that are active. When $(1/2)b^2$ is added to the objective function, b is determined by the equation

$$b = -(\mathbf{1}_p^\top \lambda - \mathbf{1}_q^\top \mu).$$

All these problems are convex and the constraints are qualified, so the duality gap is zero, and if the primal has an optimal solution with $w \neq 0$, then it follows that $\eta \geq 0$.

We now consider five variants in more details.

(1) Basic soft margin SVM: (SVM_{s2}) .

This is the optimization problem in which the regularization term $K(\epsilon^\top \xi)$ is linear and the margin δ is given by $\delta = 1/\|w\|$:

$$\begin{aligned} \text{minimize} \quad & \frac{1}{2} w^\top w + K(\epsilon^\top \xi) \mathbf{1}_{p+q} \\ \text{subject to} \quad & w^\top u_i - b \geq 1 - \epsilon_i, \quad \epsilon_i \geq 0 \quad i = 1, \dots, p \\ & -w^\top v_j + b \geq 1 - \xi_j, \quad \xi_j \geq 0 \quad j = 1, \dots, q. \end{aligned}$$

This problem is the classical one discussed in all books on machine learning or pattern analysis, for instance Vapnik [182], Bishop [23], and Shawe-Taylor and Christianini [159]. It is shown in Section 54.3 that the dual program is

Dual of the Basic soft margin SVM: (SVM_{s2}):

$$\text{minimize} \quad \frac{1}{2} (\lambda^\top - \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - (\lambda^\top - \mu^\top) \mathbf{1}_{p+q}$$

subject to

$$\sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j = 0$$

$$0 \leq \lambda_i \leq K, \quad i = 1, \dots, p$$

$$0 \leq \mu_j \leq K, \quad j = 1, \dots, q.$$

We can use the dual program to solve the primal. Once $\lambda \geq 0, \mu \geq 0$ have been found, w is given by

$$w = -X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = \sum_{i=1}^p \lambda_i u_i - \sum_{j=1}^q \mu_j v_j,$$

but b is not determined by the dual.

The complementary slackness conditions imply that if $\epsilon_i > 0$, then $\lambda_i = K$, and if $\xi_j > 0$, then $\mu_j = K$. Consequently, if $\lambda_i < K$, then $\epsilon_i = 0$ and u_i is correctly classified, and similarly if $\mu_j < K$, then $\xi_j = 0$ and v_j is correctly classified.

A priori nothing prevents the situation where $\lambda_i = K$ for all nonzero λ_i or $\mu_j = K$ for all nonzero μ_j . If this happens, we can rerun the optimization method with a larger value of K . If the following mild hypothesis holds then b can be found.

Standard Margin Hypothesis for (SVM_{s2}). There is some support vector u_{i_0} of type 1 on the blue margin, and some support vector v_{j_0} of type 1 on the red margin.

If the **Standard Margin Hypothesis** for (SVM_{s2}) holds then $\epsilon_{i_0} = 0$ and $\mu_{j_0} = 0$, and then we have the active equations

$$w^\top u_{i_0} - b = 1 \quad \text{and} \quad -w^\top v_{j_0} + b = 1,$$

and we obtain

$$b = \frac{1}{2} w^\top (u_{i_0} + v_{j_0}).$$

(2) Basic Soft margin ν -SVM Problem ($\text{SVM}_{s2'}$).

This is a generalization of Problem (SVM_{s2}) for a version of the soft margin SVM coming from Problem (SVM_{h2}), obtained by adding an extra degree of freedom, namely instead of the margin $\delta = 1/\|w\|$, we use the margin $\delta = \eta/\|w\|$ where η is some positive constant that we wish to maximize. To do so, we add a term $-K_m\eta$ to the objective function. We have the following optimization problem:

$$\begin{aligned} & \text{minimize} \quad \frac{1}{2} w^\top w - K_m\eta + K_s (\epsilon^\top \xi^\top) \mathbf{1}_{p+q} \\ & \text{subject to} \\ & \quad w^\top u_i - b \geq \eta - \epsilon_i, \quad \epsilon_i \geq 0 \quad i = 1, \dots, p \\ & \quad -w^\top v_j + b \geq \eta - \xi_j, \quad \xi_j \geq 0 \quad j = 1, \dots, q \\ & \quad \eta \geq 0, \end{aligned}$$

where $K_m > 0$ and $K_s > 0$ are fixed constants that can be adjusted to determine the influence of η and the regularizing term.

This version of the SVM problem was first discussed in Schölkopf, Smola, Williamson, and Bartlett [147] under the name of ν -SVC, and also used in Schölkopf, Platt, Shawe-Taylor, and Smola [146].

In order for the problem to have a solution we must pick K_m and K_s so that

$$K_m \leq \min\{2pK_s, 2qK_s\}.$$

It is shown in Section 54.5 that the dual program is

Dual of the Basic Soft margin ν -SVM Problem ($\text{SVM}_{s2'}$):

$$\begin{aligned} & \text{minimize} \quad \frac{1}{2} (\lambda^\top \mu^\top) X^\top X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ & \text{subject to} \\ & \quad \sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j = 0 \\ & \quad \sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j \geq K_m \\ & \quad 0 \leq \lambda_i \leq K_s, \quad i = 1, \dots, p \\ & \quad 0 \leq \mu_j \leq K_s, \quad j = 1, \dots, q. \end{aligned}$$

If the primal problem has an optimal solution with $w \neq 0$, then using the fact that the duality gap is zero we can show that $\eta \geq 0$. Thus constraint $\eta \geq 0$ could be omitted.

As in the previous case w is given by

$$w = -X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = \sum_{i=1}^p \lambda_i u_i - \sum_{j=1}^q \mu_j v_j,$$

but b and η are not determined by the dual.

If we drop the constraint $\eta \geq 0$, then the inequality

$$\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j \geq K_m$$

is replaced by the equation

$$\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j = K_m.$$

It convenient to define $\nu > 0$ such that

$$\nu = \frac{K_m}{(p+q)K_s},$$

so that the objective function $J(w, \epsilon, \xi, b, \eta)$ is given by

$$J(w, \epsilon, \xi, b, \eta) = \frac{1}{2} w^\top w + (p+q)K_s \left(-\nu \eta + \frac{1}{p+q} (\epsilon^\top \quad \xi^\top) \mathbf{1}_{p+q} \right).$$

Since we obtain an equivalent problem by rescaling by a common positive factor, theoretically it is convenient to normalize K_s as

$$K_s = \frac{1}{p+q},$$

in which case $K_m = \nu$. This method is called the ν -support vector machine.

Under the **Standard Margin Hypothesis** for $(\text{SVM}_{s2'})$, there is some support vector u_{i_0} of type 1 and some support vector v_{j_0} of type 1, and by the complementary slackness conditions $\epsilon_{i_0} = 0$ and $\xi_{j_0} = 0$, so we have the two active constraints

$$w^\top u_{i_0} - b = \eta, \quad -w^\top v_{j_0} + b = \eta,$$

and we can solve for b and η and we get

$$b = \frac{w^\top (u_{i_0} + v_{j_0})}{2}$$

$$\eta = \frac{w^\top (u_{i_0} - v_{j_0})}{2}.$$

Due to numerical instability, when writing a computer program it is preferable to compute the lists of indices I_λ and I_μ given by

$$I_\lambda = \{i \in \{1, \dots, p\} \mid 0 < \lambda_i < K_s\}, \quad I_\mu = \{j \in \{1, \dots, q\} \mid 0 < \mu_j < K_s\}.$$

Then b and η are given by the following averaging formulae:

$$\begin{aligned} b &= w^\top \left(\left(\sum_{i \in I_\lambda} u_i \right) / |I_\lambda| + \left(\sum_{j \in I_\mu} v_j \right) / |I_\mu| \right) / 2 \\ \eta &= w^\top \left(\left(\sum_{i \in I_\lambda} u_i \right) / |I_\lambda| - \left(\sum_{j \in I_\mu} v_j \right) / |I_\mu| \right) / 2. \end{aligned}$$

Proposition 54.1 yields bounds on ν for the method to converge, namely

$$\max \left\{ \frac{2p_f}{p+q}, \frac{2q_f}{p+q} \right\} \leq \nu \leq \min \left\{ \frac{2p_m}{p+q}, \frac{2q_m}{p+q} \right\}.$$

In Section 54.7 we investigate conditions on ν that ensure that some point u_{i_0} and some point v_{j_0} is a support vector. Theorem 54.3 shows that for every optimal solution $(w, b, \eta, \epsilon, \xi)$ of Problem (SVM_{s2'}) with $w \neq 0$ and $\eta > 0$, if

$$\max\{2p_f/(p+q), 2q_f/(p+q)\} < \nu < \min\{2p/(p+q), 2q/(p+q)\},$$

then some u_{i_0} and some v_{j_0} is a support vector. Under the same conditions on ν Proposition 54.4 shows that η and b can always be determined in terms of (λ, μ) using a single support vector.

- (3) **Soft margin ν -SVM Problem (SVM_{s3}).** This is the variation of Problem (SVM_{s2'}) obtained by adding the term $(1/2)b^2$ to the objective function. The result is that in minimizing the Lagrangian to find the dual function G , not just w but also b is determined. We also suppress the constraint $\eta \geq 0$ which turns out to be redundant. If $\nu > (p_f + q_f)/(p+q)$, then η is also determined. The fact that b and η are determined by the dual seems to be an advantage of Problem (SVM_{s3}).

The optimization problem is

$$\begin{aligned} \text{minimize} \quad & \frac{1}{2} w^\top w + \frac{1}{2} b^2 + (p+q)K_s \left(-\nu\eta + \frac{1}{p+q} (\epsilon^\top \quad \xi^\top) \mathbf{1}_{p+q} \right) \\ \text{subject to} \quad & w^\top u_i - b \geq \eta - \epsilon_i, \quad \epsilon_i \geq 0 \quad i = 1, \dots, p \\ & -w^\top v_j + b \geq \eta - \xi_j, \quad \xi_j \geq 0 \quad j = 1, \dots, q. \end{aligned}$$

Theoretically it is convenient to assume that $K_s = 1/(p+q)$. Otherwise, ν needs to be replaced by $(p+q)K_s\nu$ in all the formulae below.

It is shown in Section 54.13 that the dual is given by

Dual of the Soft margin ν -SVM Problem (SVM_{s3}):

$$\text{minimize} \quad \frac{1}{2} (\lambda^\top - \mu^\top) \left(X^\top X + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}$$

subject to

$$\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j = \nu$$

$$0 \leq \lambda_i \leq K_s, \quad i = 1, \dots, p$$

$$0 \leq \mu_j \leq K_s, \quad j = 1, \dots, q.$$

Once a solution for λ and μ is obtained, we have

$$w = -X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = \sum_{i=1}^p \lambda_i u_i - \sum_{j=1}^q \mu_j v_j$$

$$b = -\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j.$$

Note that the constraint

$$\sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j = 0$$

occurring in the dual of Program (SVM_{s2'}) has been traded for the equation

$$b = -\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j$$

determining b .

If $\nu > (p_f + q_f)/(p+q)$, then η is determined by expressing that the duality gap is zero. We obtain

$$((p+q)\nu - p_f - q_f)\eta = (p_f - q_f)b + w^\top \left(\sum_{j \in K_\mu} v_j - \sum_{i \in K_\lambda} u_i \right)$$

$$+ \frac{1}{K_s} (\lambda^\top - \mu^\top) \left(X^\top X + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}.$$

In practice another way to compute η is to assume the Standard Margin Hypothesis for (SVM_{s3}) . Under the **Standard Margin Hypothesis** for (SVM_{s3}) , either some u_{i_0} is a support vector of type 1 or some v_{j_0} is a support vector of type 1. By the complementary slackness conditions $\epsilon_{i_0} = 0$ or $\xi_{j_0} = 0$, so we have

$$w^\top u_{i_0} - b = \eta, \quad \text{or} \quad -w^\top v_{j_0} + b = \eta,$$

and we can solve for η . As in $(\text{SVM}_{s2'})$ we get more numerically stable formulae by averaging over the sets I_λ and I_μ .

Proposition 54.5 gives bounds ν , namely

$$\frac{p_f + q_f}{p + q} \leq \nu \leq \frac{p_m + q_m}{p + q}.$$

In Section 54.11 we investigate conditions on ν that ensure that either there is some blue support vector u_{i_0} or there is some red support vector v_{j_0} . Theorem 54.7 shows that for every optimal solution $(w, b, \eta, \epsilon, \xi)$ of Problem (SVM_{s3}) with $w \neq 0$ and $\eta > 0$, if

$$(p_{sf} + q_{sf})/(p + q) < \nu < 1,$$

then some u_{i_0} or some v_{j_0} is a support vector.

- (4) **Basic Quadratic Soft margin ν -SVM Problem (SVM_{s4})**. This is the version of Problem $(\text{SVM}_{s2'})$ in which instead of using the linear function $K_s(\epsilon^\top \xi^\top) \mathbf{1}_{p+q}$ as a regularizing function we use the quadratic function $K(\|\epsilon\|_2^2 + \|\xi\|_2^2)$. The optimization problem is

$$\begin{aligned} \text{minimize} \quad & \frac{1}{2} w^\top w + (p + q) K_s \left(-\nu \eta + \frac{1}{p + q} (\epsilon^\top \epsilon + \xi^\top \xi) \right) \\ \text{subject to} \quad & w^\top u_i - b \geq \eta - \epsilon_i, \quad i = 1, \dots, p \\ & -w^\top v_j + b \geq \eta - \xi_j, \quad j = 1, \dots, q \\ & \eta \geq 0, \end{aligned}$$

where ν and K_s are two given positive constants. As we saw earlier, theoretically, it is convenient to pick $K_s = 1/(p + q)$. When writing a computer program, it is preferable to assume that K_s is arbitrary. In this case ν needs to be replaced by $(p + q)K_s\nu$ in all the formulae obtained with $K_s = 1/(p + q)$.

In this method, it is no longer necessary to require $\epsilon \geq 0$ and $\xi \geq 0$, because an optimal solution satisfies these conditions.

One of the advantages of this methods is that ϵ is determined by λ , ξ is determined by μ , and η and b are determined by λ and μ . We can omit the constraint $\eta \geq 0$, because

for an optimal solution it can be shown using duality that $\eta \geq 0$; see Section 54.14. For K_s and ν fixed, if Program (SVM_{s4}) has an optimal solution, then it is unique; see Theorem 54.8.

A drawback of Program (SVM_{s4}) is that for fixed K_s , the quantity $\delta = \eta / \|w\|$ and the hyperplanes $H_{w,b}$, $H_{w,b+\eta}$ and $H_{w,b-\eta}$ are *independent* of ν . This is shown in Theorem 54.8. Thus this method is less flexible than $(\text{SVM}_{s2'})$ and (SVM_{s3}) .

It is shown in Section 54.9 that the dual is given by

Dual of the Basic Quadratic Soft margin ν -SVM Problem (SVM_{s4}) :

$$\text{minimize} \quad \frac{1}{2} (\lambda^\top - \mu^\top) \left(X^\top X + \frac{1}{2K} I_{p+q} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}$$

subject to

$$\sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j = 0$$

$$\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j \geq \nu$$

$$\lambda_i \geq 0, \quad i = 1, \dots, p$$

$$\mu_j \geq 0, \quad j = 1, \dots, q.$$

The above program is similar to the program that was obtained for Problem $(\text{SVM}_{s2'})$ but the matrix $X^\top X$ is replaced by the matrix $X^\top X + (1/2K)I_{p+q}$, which is positive definite since $K > 0$, and also the inequalities $\lambda_i \leq K$ and $\mu_j \leq K$ no longer hold. If the constraint $\eta \geq 0$ is dropped, then the inequality

$$\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j \geq \nu$$

is replaced by the equation

$$\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j = \nu.$$

We obtain w from λ and μ , and γ , as in Problem $(\text{SVM}_{s2'})$; namely,

$$w = -X \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = \sum_{i=1}^p \lambda_i u_i - \sum_{j=1}^q \mu_j v_j$$

and η is given by

$$(p+q)K_s\nu\eta = (\lambda^\top \mu^\top) \left(X^\top X + \frac{1}{2K_s} I_{p+q} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}.$$

The constraints imply that there is some i_0 such that $\lambda_{i_0} > 0$ and some j_0 such that $\mu_{j_0} > 0$, which means that at least two points are misclassified, so Problem (SVM_{s4}) should only be used when the sets $\{u_i\}$ and $\{v_j\}$ are *not* linearly separable. We can solve for b using the active constraints corresponding to any i_0 such that $\lambda_{i_0} > 0$ and any j_0 such that $\mu_{j_0} > 0$. To improve numerical stability we average over the sets of indices I_λ and I_μ .

- (5) **Quadratic Soft margin ν -SVM Problem (SVM_{s5})**. This is the variant of Problem (SVM_{s4}) in which we add the term $(1/2)b^2$ to the objective function. We also drop the constraint $\eta \geq 0$ which is redundant. We have the following optimization problem:

$$\begin{aligned} \text{minimize} \quad & \frac{1}{2}w^\top w + \frac{1}{2}b^2 + (p+q)K_s \left(-\nu\eta + \frac{1}{p+q}(\epsilon^\top \epsilon + \xi^\top \xi) \right) \\ \text{subject to} \quad & w^\top u_i - b \geq \eta - \epsilon_i, \quad i = 1, \dots, p \\ & -w^\top v_j + b \geq \eta - \xi_j, \quad j = 1, \dots, q, \end{aligned}$$

where ν and K_s are two given positive constants. As we saw earlier, it is convenient to pick $K_s = 1/(p+q)$. When writing a computer program, it is preferable to assume that K_s is arbitrary. In this case ν must be replaced by $(p+q)K_s\nu$ in all the formulae.

One of the advantages of this methods is that ϵ is determined by λ , ξ is determined by μ (as in (SVM_{s4})), and both η and b determined by λ and μ . We can omit the constraint $\eta \geq 0$, because for an optimal solution it can be shown using duality that $\eta \geq 0$. For K_s and ν fixed, if Program (SVM_{s5}) has an optimal solution, then it is unique; see Theorem 54.9.

A drawback of Program (SVM_{s5}) is that for fixed K_s , the quantity $\delta = \eta/\|w\|$ and the hyperplanes $H_{w,b}$, $H_{w,b+\eta}$ and $H_{w,b-\eta}$ are *independent* of ν . This is shown in Theorem 54.9. Thus this method is less flexible than (SVM_{s2'}) and (SVM_{s3}).

It is shown in Section 54.15 that the dual of Program (SVM_{s5}) is given by

Dual of the Quadratic Soft margin ν -SVM Problem (SVM_{s5}):

$$\text{minimize} \quad \frac{1}{2} (\lambda^\top - \mu^\top) \left(X^\top X + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix} + \frac{1}{2K} I_{p+q} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}$$

subject to

$$\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j = \nu$$

$$\lambda_i \geq 0, \quad i = 1, \dots, p$$

$$\mu_j \geq 0, \quad j = 1, \dots, q.$$

This time we obtain w , b , η , ϵ and ξ from λ and μ :

$$w = \sum_{i=1}^p \lambda_i u_i - \sum_{j=1}^q \mu_j v_j$$

$$b = - \sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j$$

$$\epsilon = \frac{\lambda}{2K}$$

$$\xi = \frac{\mu}{2K},$$

and

$$(p+q)K_s\nu\eta = (\lambda^\top - \mu^\top) \left(X^\top X + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix} + \frac{1}{2K_s} I_{p+q} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}.$$

The constraint

$$\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j = \nu$$

implies that either there is some i_0 such that $\lambda_{i_0} > 0$ or there is some j_0 such that $\mu_{j_0} > 0$, we have $\epsilon_{i_0} > 0$ or $\xi_{j_0} > 0$, which means that **at least one point is misclassified**, so Problem (SVM_{s5}) should only be used when the sets $\{u_i\}$ and $\{v_j\}$ are *not* linearly separable.

These methods all have a kernelized version.

We implemented all these methods in **Matlab**, solving the dual using ADMM.

From a theoretical point of view, Problems (SVM_{s4}) and (SVM_{s5}) seem to have more advantages than the others since they determine w , b , η and b without requiring any condition about support vectors of type 1. However, from a practical point of view, Problems (SVM_{s4}) and (SVM_{s5}) are less flexible than (SVM_{s2'}) and (SVM_{s3}), and we have observed that (SVM_{s4}) and (SVM_{s5}) are unable to produce as small a margin δ as (SVM_{s2'}) and (SVM_{s3}).

54.18 Problems

Problem 54.1. Prove the following inequality

$$\max \left\{ \frac{1}{2p_m}, \frac{1}{2q_m} \right\} \leq K \leq \min \left\{ \frac{1}{2p_f}, \frac{1}{2q_f} \right\}$$

stated just after Definition 54.1.

Problem 54.2. Prove the averaging formulae

$$b = w^\top \left(\left(\sum_{i \in I_\lambda} u_i \right) / |I_\lambda| + \left(\sum_{j \in I_\mu} v_j \right) / |I_\mu| \right) / 2$$

$$\delta = w^\top \left(\left(\sum_{i \in I_\lambda} u_i \right) / |I_\lambda| - \left(\sum_{j \in I_\mu} v_j \right) / |I_\mu| \right) / 2$$

stated at the end of Section 54.1.

Problem 54.3. Prove that the matrix

$$A = \begin{pmatrix} \mathbf{1}_p^\top & -\mathbf{1}_q^\top & 0_p^\top & 0_q^\top \\ \mathbf{1}_p^\top & \mathbf{1}_q^\top & 0_p^\top & 0_q^\top \\ I_p & 0_{p,q} & I_p & 0_{p,q} \\ 0_{q,p} & I_q & 0_{q,p} & I_q \end{pmatrix}$$

has rank $p + q + 2$.

Problem 54.4. Prove that the dual program of the kernel version of (SVM_{s1}) is given by:

Dual of Soft margin kernel SVM (SVM_{s1}):

$$\text{minimize} \quad (\lambda^\top \quad \mu^\top) \mathbf{K} \begin{pmatrix} \lambda \\ \mu \end{pmatrix}$$

subject to

$$\sum_{i=1}^p \lambda_i = \sum_{j=1}^q \mu_j = \frac{1}{2}$$

$$0 \leq \lambda_i \leq K, \quad i = 1, \dots, p$$

$$0 \leq \mu_j \leq K, \quad j = 1, \dots, q,$$

where \mathbf{K} is the $\ell \times \ell$ kernel symmetric matrix (with $\ell = p + q$) given by

$$\mathbf{K}_{ij} = \begin{cases} \kappa(u_i, u_j) & 1 \leq i \leq p, 1 \leq j \leq q \\ -\kappa(u_i, v_{j-p}) & 1 \leq i \leq p, p+1 \leq j \leq p+q \\ -\kappa(v_{i-p}, u_j) & p+1 \leq i \leq p+q, 1 \leq j \leq p \\ \kappa(v_{i-p}, v_{j-q}) & p+1 \leq i \leq p+q, p+1 \leq j \leq p+q. \end{cases}$$

Problem 54.5. Prove the averaging formula

$$b = w^\top \left(\left(\sum_{i \in I_\lambda} u_i \right) / |I_\lambda| + \left(\sum_{j \in I_\mu} v_j \right) / |I_\mu| \right) / 2$$

stated in Section 54.3.

Problem 54.6. Prove that the kernel version of Program (SVM_{s2}) is given by:

Dual of Soft margin kernel SVM (SVM_{s2}):

$$\text{minimize } \frac{1}{2} (\lambda^\top \mu^\top) \mathbf{K} \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - (\lambda^\top \mu^\top) \mathbf{1}_{p+q}$$

subject to

$$\sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j = 0$$

$$0 \leq \lambda_i \leq K, \quad i = 1, \dots, p$$

$$0 \leq \mu_j \leq K, \quad j = 1, \dots, q,$$

where \mathbf{K} is the $\ell \times \ell$ kernel symmetric matrix (with $\ell = p + q$) given at the end of Section 54.1.

Problem 54.7. Prove that the matrix

$$A = \begin{pmatrix} \mathbf{1}_p^\top & -\mathbf{1}_q^\top & 0_p^\top & 0_q^\top \\ I_p & 0_{p,q} & I_p & 0_{p,q} \\ 0_{q,p} & I_q & 0_{q,p} & I_q \end{pmatrix}$$

has rank $p + q + 1$.

Problem 54.8. Prove that the matrices

$$A = \begin{pmatrix} \mathbf{1}_p^\top & -\mathbf{1}_q^\top & 0_p^\top & 0_q^\top & 0 \\ \mathbf{1}_p^\top & \mathbf{1}_q^\top & 0_p^\top & 0_q^\top & -1 \\ I_p & 0_{p,q} & I_p & 0_{p,q} & 0_p \\ 0_{q,p} & I_q & 0_{q,p} & I_q & 0_q \end{pmatrix} \quad \text{and} \quad A_2 = \begin{pmatrix} \mathbf{1}_p^\top & -\mathbf{1}_q^\top & 0_p^\top & 0_q^\top \\ \mathbf{1}_p^\top & \mathbf{1}_q^\top & 0_p^\top & 0_q^\top \\ I_p & 0_{p,q} & I_p & 0_{p,q} \\ 0_{q,p} & I_q & 0_{q,p} & I_q \end{pmatrix}$$

have rank $p + q + 2$.

Problem 54.9. Prove that the kernel version of Program (SVM_{s2'}) is given by:

Dual of the Soft margin kernel SVM (SVM_{s2'}):

$$\text{minimize} \quad \frac{1}{2} (\lambda^\top \mu^\top) \mathbf{K} \begin{pmatrix} \lambda \\ \mu \end{pmatrix}$$

subject to

$$\sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j = 0$$

$$\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j \geq K_m$$

$$0 \leq \lambda_i \leq K_s, \quad i = 1, \dots, p$$

$$0 \leq \mu_j \leq K_s, \quad j = 1, \dots, q,$$

where \mathbf{K} is the kernel matrix of Section 54.1.

Problem 54.10. Prove the formulae determining b in terms of η stated just before Theorem 54.8.

Problem 54.11. Prove that the matrix

$$A = \begin{pmatrix} \mathbf{1}_p^\top & \mathbf{1}_q^\top & 0_p^\top & 0_q^\top \\ I_p & 0_{p,q} & I_p & 0_{p,q} \\ 0_{q,p} & I_q & 0_{q,p} & I_q \end{pmatrix}$$

has rank $p + q + 1$.

Problem 54.12. Prove that the kernel version of Program (SVM_{s3}) is given by:

Dual of the Soft margin kernel SVM (SVM_{s3}):

$$\text{minimize} \quad \frac{1}{2} (\lambda^\top \mu^\top) \left(\mathbf{K} + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}$$

subject to

$$\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j = \nu$$

$$0 \leq \lambda_i \leq K_s, \quad i = 1, \dots, p$$

$$0 \leq \mu_j \leq K_s, \quad j = 1, \dots, q,$$

where \mathbf{K} is the kernel matrix of Section 54.1.

Problem 54.13. Prove that the matrices

$$A = \begin{pmatrix} \mathbf{1}_p^\top & -\mathbf{1}_q^\top & 0 \\ \mathbf{1}_p^\top & \mathbf{1}_q^\top & -1 \end{pmatrix} \quad \text{and} \quad A_2 = \begin{pmatrix} \mathbf{1}_p^\top & -\mathbf{1}_q^\top \\ \mathbf{1}_p^\top & \mathbf{1}_q^\top \end{pmatrix}$$

have rank 2.

Problem 54.14. Implement Program (SVM_{s4}) in Matlab. You may adapt the programs given in Section B.2 and Section B.3.

Problem 54.15. Prove that the kernel version of Program (SVM_{s4}) is given by:

Dual of the Soft margin kernel SVM (SVM_{s4}):

$$\text{minimize} \quad \frac{1}{2} (\lambda^\top \mu^\top) \left(\mathbf{K} + \frac{p+q}{2} I_{p+q} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}$$

subject to

$$\sum_{i=1}^p \lambda_i - \sum_{j=1}^q \mu_j = 0$$

$$\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j \geq \nu$$

$$\lambda_i \geq 0, \quad i = 1, \dots, p$$

$$\mu_j \geq 0, \quad j = 1, \dots, q,$$

where \mathbf{K} is the kernel matrix of Section 54.1.

Problem 54.16. Implement Program (SVM_{s5}) in Matlab. You may adapt the programs given in Section B.2 and Section B.3.

Problem 54.17. Prove that the kernel version of Program (SVM_{s5}) is given by:

Dual of the Soft margin kernel SVM (SVM_{s5}):

$$\text{minimize} \quad \frac{1}{2} (\lambda^\top \mu^\top) \left(\mathbf{K} + \begin{pmatrix} \mathbf{1}_p \mathbf{1}_p^\top & -\mathbf{1}_p \mathbf{1}_q^\top \\ -\mathbf{1}_q \mathbf{1}_p^\top & \mathbf{1}_q \mathbf{1}_q^\top \end{pmatrix} + \frac{p+q}{2} I_{p+q} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}$$

subject to

$$\sum_{i=1}^p \lambda_i + \sum_{j=1}^q \mu_j = \nu$$

$$\lambda_i \geq 0, \quad i = 1, \dots, p$$

$$\mu_j \geq 0, \quad j = 1, \dots, q,$$

where \mathbf{K} is the kernel matrix of Section 54.1.

Chapter 55

Ridge Regression, Lasso, Elastic Net

In this chapter we discuss linear regression. This problem can be cast as a learning problem. We observe a sequence of (distinct) pairs $((x_1, y_1), \dots, (x_m, y_m))$ called a *set of training data* (or *predictors*), where $x_i \in \mathbb{R}^n$ and $y_i \in \mathbb{R}$, viewed as input-output pairs of some unknown function f that we are trying to infer. The simplest kind of function is a linear function $f(x) = x^\top w$, where $w \in \mathbb{R}^n$ is a vector of coefficients usually called a *weight vector*. Since the problem is overdetermined and since our observations may be subject to errors, we can't solve for w exactly as the solution of the system $Xw = y$, where X is the $m \times n$ matrix

$$X = \begin{pmatrix} x_1^\top \\ \vdots \\ x_m^\top \end{pmatrix},$$

where the row vectors x_i^\top are the rows of X , and thus the $x_i \in \mathbb{R}^n$ are column vectors. So instead we solve the least-squares problem of minimizing $\|Xw - y\|_2^2$. In general there are still infinitely many solutions so we add a regularizing term. If we add the term $K \|w\|_2^2$ to the objective function $J(w) = \|Xw - y\|_2^2$, then we have *ridge regression*. This problem is discussed in Section 55.1 where we derive the dual program. The dual has a unique solution which yields a solution of the primal. However, the solution of the dual is given in terms of the matrix XX^\top (whereas the solution of the primal is given in terms of $X^\top X$), and since our data points x_i are represented by the rows of the matrix X , we see that this solution only involves inner products of the x_i . This observation is the core of the idea of kernel functions, which were discussed in Chapter 53. We also explain how to solve the problem of learning an affine function $f(x) = x^\top w + b$.

In general the vectors w produced by ridge regression have few zero entries. In practice it is highly desirable to obtain sparse solutions, that is vectors w with many components equal to zero. This can be achieved by replacing the regularizing term $K \|w\|_2^2$ by the regularizing term $K \|w\|_1$; that is, to use the ℓ^1 -norm instead of the ℓ^2 -norm; see Section 55.4. This method has the exotic name of *lasso regression*. This time there is no closed-form solution, but this is a convex optimization problem and there are efficient iterative methods to solve

it. One of the best methods relies on ADMM (see Section 52.8) and is discussed in Section 55.4. The lasso method has some limitations, in particular when the number m of data is smaller than the dimension n of the data. This happens in some applications in genetics and medicine. Fortunately there is a way to combine the best features of ridge regression and lasso, which is to use *two* regularizing terms:

1. An ℓ^2 -term $(1/2)K \|w\|_2^2$ as in ridge regression (with $K > 0$).
2. An ℓ^1 -term $\tau \|w\|_1$ as in lasso.

This method is known as *elastic net regression* and is discussed in Section 55.6. It retains most of the desirable features of ridge regression and lasso, and eliminates some of their weaknesses. Furthermore, it is effectively solved by ADMM.

55.1 Ridge Regression

The problem of solving an overdetermined or underdetermined linear system $Aw = y$, where A is an $m \times n$ matrix, arises as a “learning problem” in which we observe a sequence of data $((a_1, y_1), \dots, (a_m, y_m))$, viewed as input-output pairs of some unknown function f that we are trying to infer, where the a_i are the *rows* of the matrix A and $y_i \in \mathbb{R}$. The values y_i are sometimes called *labels* or *responses*. The simplest kind of function is a linear function $f(x) = x^\top w$, where $w \in \mathbb{R}^n$ is a vector of coefficients usually called a *weight vector*, or sometimes an *estimator*. In the statistical literature w is often denoted by β . Since the problem is overdetermined and since our observations may be subject to errors, we can’t solve for w exactly as the solution of the system $Aw = y$, so instead we solve the least-square problem of minimizing $\|Aw - y\|_2^2$.

In Section 23.1 we showed that this problem can be solved using the pseudo-inverse. We know that the minimizers w are solutions of the normal equations $A^\top Aw = A^\top y$, but when $A^\top A$ is not invertible, such a solution is not unique so some criterion has to be used to choose among these solutions.

One solution is to pick the unique vector w^+ of smallest Euclidean norm $\|w^+\|_2$ that minimizes $\|Aw - y\|_2^2$. The solution w^+ is given by $w^+ = A^+y$, where A^+ is the pseudo-inverse of A . The matrix A^+ is obtained from an SVD of A , say $A = V\Sigma U^\top$. Namely, $A^+ = U\Sigma^+V^\top$, where Σ^+ is the matrix obtained from Σ by replacing every nonzero singular value σ_i in Σ by σ_i^{-1} , leaving all zeros in place, and then transposing. The difficulty with this approach is that it requires knowing whether a singular value is zero or very small but nonzero. A very small nonzero singular value σ in Σ yields a very large value σ^{-1} in Σ^+ , but $\sigma = 0$ remains 0 in Σ^+ .

This discontinuity phenomenon is not desirable and another way is to control the size of w by adding a regularization term to $\|Aw - y\|^2$, and a natural candidate is $\|w\|^2$.

It is customary to rename each column vector a_i^\top as x_i (where $x_i \in \mathbb{R}^n$) and to rename the input data matrix A as X , so that the row vector x_i^\top are the *rows* of the $m \times n$ matrix X

$$X = \begin{pmatrix} x_1^\top \\ \vdots \\ x_m^\top \end{pmatrix}.$$

Our optimization problem, called *ridge regression*, is

Program (RR1):

$$\text{minimize } \|y - Xw\|^2 + K \|w\|^2,$$

which by introducing the new variable $\xi = y - Xw$ can be rewritten as

Program (RR2):

$$\begin{aligned} & \text{minimize } \xi^\top \xi + Kw^\top w \\ & \text{subject to} \\ & \quad y - Xw = \xi, \end{aligned}$$

where $K > 0$ is some constant determining the influence of the regularizing term $w^\top w$, and we minimize over ξ and w .

The objective function of the first version of our minimization problem can be expressed as

$$\begin{aligned} J(w) &= \|y - Xw\|^2 + K \|w\|^2 \\ &= (y - Xw)^\top (y - Xw) + Kw^\top w \\ &= y^\top y - 2w^\top X^\top y + w^\top X^\top Xw + Kw^\top w \\ &= w^\top (X^\top X + KI_n)w - 2w^\top X^\top y + y^\top y. \end{aligned}$$

The matrix $X^\top X$ is symmetric positive semidefinite and $K > 0$, so the matrix $X^\top X + KI_n$ is positive definite. It follows that

$$J(w) = w^\top (X^\top X + KI_n)w - 2w^\top X^\top y + y^\top y$$

is strictly convex, so by Theorem 40.13(2)-(4), it has a unique minimum iff $\nabla J_w = 0$. Since

$$\nabla J_w = 2(X^\top X + KI_n)w - 2X^\top y,$$

we deduce that

$$w = (X^\top X + KI_n)^{-1} X^\top y. \quad (*_{wp})$$

There is an interesting connection between the matrix $(X^\top X + KI_n)^{-1} X^\top$ and the pseudo-inverse X^+ of X .

Proposition 55.1. *The limit of the matrix $(X^\top X + KI_n)^{-1}X^\top$ when $K > 0$ goes to zero is the pseudo-inverse X^+ of X .*

Proof. To show this let $X = V\Sigma U^\top$ be a SVD of X . Then

$$(X^\top X + KI_n) = U\Sigma^\top V^\top V\Sigma U^\top + KI_n = U(\Sigma^\top \Sigma + KI_n)U^\top,$$

so

$$(X^\top X + KI_n)^{-1}X^\top = U(\Sigma^\top \Sigma + KI_n)^{-1}U^\top U\Sigma^\top V^\top = U(\Sigma^\top \Sigma + KI_n)^{-1}\Sigma^\top V^\top.$$

The diagonal entries in the matrix $(\Sigma^\top \Sigma + KI_n)^{-1}\Sigma^\top$ are

$$\frac{\sigma_i}{\sigma_i^2 + K}, \quad \text{if } \sigma_i > 0,$$

and zero if $\sigma_i = 0$. All nondiagonal entries are zero. When $\sigma_i > 0$ and $K > 0$ goes to 0,

$$\lim_{K \rightarrow 0} \frac{\sigma_i}{\sigma_i^2 + K} = \sigma_i^{-1},$$

so

$$\lim_{K \rightarrow 0} (\Sigma^\top \Sigma + KI_n)^{-1}\Sigma^\top = \Sigma^+,$$

which implies that

$$\lim_{K \rightarrow 0} (X^\top X + KI_n)^{-1}X^\top = X^+. \quad \square$$

The dual function of the first formulation of our problem is a constant function (with value the minimum of J) so it is not useful, but the second formulation of our problem yields an interesting dual problem. The Lagrangian is

$$\begin{aligned} L(\xi, w, \lambda) &= \xi^\top \xi + Kw^\top w + (y - Xw - \xi)^\top \lambda \\ &= \xi^\top \xi + Kw^\top w - w^\top X^\top \lambda - \xi^\top \lambda + \lambda^\top y, \end{aligned}$$

with $\lambda, \xi, y \in \mathbb{R}^m$. The Lagrangian $L(\xi, w, \lambda)$, as a function of ξ and w with λ held fixed, is obviously convex, in fact strictly convex.

To derive the dual function $G(\lambda)$ we minimize $L(\xi, w, \lambda)$ with respect to ξ and w . Since $L(\xi, w, \lambda)$ is (strictly) convex as a function of ξ and w , by Theorem 40.13(4), it has a minimum iff its gradient $\nabla L_{\xi, w}$ is zero (in fact, by Theorem 40.13(2), a unique minimum since the function is strictly convex). Since

$$\nabla L_{\xi, w} = \begin{pmatrix} 2\xi - \lambda \\ 2Kw - X^\top \lambda \end{pmatrix},$$

we get

$$\begin{aligned} \lambda &= 2\xi \\ w &= \frac{1}{2K}X^\top \lambda = X^\top \frac{\xi}{K}. \end{aligned}$$

The above suggests defining the variable α so that $\xi = K\alpha$, so we have $\lambda = 2K\alpha$ and $w = X^\top \alpha$. Then we obtain the dual function as a function of α by substituting the above values of ξ , λ and w back in the Lagrangian and we get

$$\begin{aligned} G(\alpha) &= K^2 \alpha^\top \alpha + K \alpha^\top X X^\top \alpha - 2K \alpha^\top X X^\top \alpha - 2K^2 \alpha^\top \alpha + 2K \alpha^\top y \\ &= -K \alpha^\top (X X^\top + K I_m) \alpha + 2K \alpha^\top y. \end{aligned}$$

This is a strictly concave function so by Theorem 40.13(4), its maximum is achieved iff $\nabla G_\alpha = 0$, that is,

$$2K(X X^\top + K I_m) \alpha = 2K y,$$

which yields

$$\alpha = (X X^\top + K I_m)^{-1} y.$$

Putting everything together we obtain

$$\begin{aligned} \alpha &= (X X^\top + K I_m)^{-1} y \\ w &= X^\top \alpha \\ \xi &= K \alpha, \end{aligned}$$

which yields

$$w = X^\top (X X^\top + K I_m)^{-1} y. \quad (*_{wd})$$

Earlier in $(*_{wp})$ we found that

$$w = (X^\top X + K I_n)^{-1} X^\top y,$$

and it is easy to check that

$$(X^\top X + K I_n)^{-1} X^\top = X^\top (X X^\top + K I_m)^{-1}.$$

If $n < m$ it is cheaper to use the formula on the left-hand side, but if $m < n$ it is cheaper to use the formula on the right-hand side.

55.2 Ridge Regression; Learning an Affine Function

It is easy to adapt the above method to learn an affine function $f(x) = x^\top w + b$ instead of a linear function $f(x) = x^\top w$, where $b \in \mathbb{R}$. We have the following optimization program

Program (RR3):

$$\begin{aligned} &\text{minimize} \quad \xi^\top \xi + K w^\top w \\ &\text{subject to} \\ &\quad y - X w - b \mathbf{1} = \xi, \end{aligned}$$

with $y, \xi, \mathbf{1} \in \mathbb{R}^m$ and $w \in \mathbb{R}^n$. Note that in Program **(RR3)** minimization is performed over ξ, w and b , but b is not penalized in the objective function. As in Section 55.1, the objective function is strictly convex.

The Lagrangian associated with this program is

$$L(\xi, w, b, \lambda) = \xi^\top \xi + Kw^\top w - w^\top X^\top \lambda - \xi^\top \lambda - b\mathbf{1}^\top \lambda + \lambda^\top y.$$

Since L is (strictly) convex as a function of ξ, b, w , by Theorem 40.13(4), it has a minimum iff $\nabla L_{\xi, b, w} = 0$. We get

$$\begin{aligned}\lambda &= 2\xi \\ \mathbf{1}^\top \lambda &= 0 \\ w &= \frac{1}{2K}X^\top \lambda = X^\top \frac{\xi}{K}.\end{aligned}$$

As before, if we set $\xi = K\alpha$ we obtain $\lambda = 2K\alpha$, $w = X^\top \alpha$, and

$$G(\alpha) = -K\alpha^\top (XX^\top + KI_m)\alpha + 2K\alpha^\top y.$$

Since $K > 0$ and $\lambda = 2K\alpha$, the dual to ridge regression is the following program

Program (DRR3):

$$\begin{aligned}&\text{minimize } \alpha^\top (XX^\top + KI_m)\alpha - 2\alpha^\top y \\ &\text{subject to} \\ &\quad \mathbf{1}^\top \alpha = 0,\end{aligned}$$

where the minimization is over α .

Observe that up to the factor 1/2, this problem satisfies the conditions of Proposition 42.3 with

$$\begin{aligned}A &= (XX^\top + KI_m)^{-1} \\ b &= y \\ B &= \mathbf{1}_m \\ f &= 0,\end{aligned}$$

and x renamed as α . Therefore, it has a unique solution (α, μ) (beware that $\lambda = 2K\alpha$ is **not** the λ used in Proposition 42.3, which we rename as μ), which is the unique solution of the KKT-equations

$$\begin{pmatrix} XX^\top + KI_m & \mathbf{1}_m \\ \mathbf{1}_m^\top & 0 \end{pmatrix} \begin{pmatrix} \alpha \\ \mu \end{pmatrix} = \begin{pmatrix} y \\ 0 \end{pmatrix}.$$

Since the solution given by Proposition 42.3 is

$$\mu = (B^\top AB)^{-1}(B^\top Ab - f), \quad \alpha = A(b - B\mu),$$

we get

$$\mu = (\mathbf{1}^\top (XX^\top + KI_m)^{-1} \mathbf{1})^{-1} \mathbf{1}^\top (XX^\top + KI_m)^{-1} y, \quad \alpha = (XX^\top + KI_m)^{-1} (y - \mu \mathbf{1}).$$

Note that the matrix $B^\top AB$ is the scalar $\mathbf{1}^\top (XX^\top + KI_m)^{-1} \mathbf{1}$, which is the negative of the Schur complement of $XX^\top + KI_m$.

Interestingly $b = \mu$, which is not obvious a priori.

Proposition 55.2. *We have $b = \mu$.*

Proof. To prove this result we need to express α differently. Since μ is a scalar, $\mu \mathbf{1} = \mathbf{1}\mu$, so

$$\mu \mathbf{1} = \mathbf{1}\mu = (\mathbf{1}^\top (XX^\top + KI_m)^{-1} \mathbf{1})^{-1} \mathbf{1} \mathbf{1}^\top (XX^\top + KI_m)^{-1} y,$$

and we obtain

$$\alpha = (XX^\top + KI_m)^{-1} (I_m - (\mathbf{1}^\top (XX^\top + KI_m)^{-1} \mathbf{1})^{-1} \mathbf{1} \mathbf{1}^\top (XX^\top + KI_m)^{-1}) y. \quad (*_{\alpha_3})$$

Since $w = X^\top \alpha$, we have

$$w = X^\top (XX^\top + KI_m)^{-1} (I_m - (\mathbf{1}^\top (XX^\top + KI_m)^{-1} \mathbf{1})^{-1} \mathbf{1} \mathbf{1}^\top (XX^\top + KI_m)^{-1}) y. \quad (*_{w_3})$$

From $\xi = K\alpha$, we deduce that b is given by the equation

$$b \mathbf{1} = y - Xw - K\alpha.$$

Since $w = X^\top \alpha$, using $(*_{\alpha_3})$ we obtain

$$\begin{aligned} b \mathbf{1} &= y - Xw - K\alpha \\ &= y - (XX^\top + KI_m)\alpha \\ &= y - (I_m - (\mathbf{1}^\top (XX^\top + KI_m)^{-1} \mathbf{1})^{-1} \mathbf{1} \mathbf{1}^\top (XX^\top + KI_m)^{-1}) y \\ &= (\mathbf{1}^\top (XX^\top + KI_m)^{-1} \mathbf{1})^{-1} \mathbf{1} \mathbf{1}^\top (XX^\top + KI_m)^{-1} y \\ &= \mu \mathbf{1}, \end{aligned}$$

and thus

$$b = \mu = (\mathbf{1}^\top (XX^\top + KI_m)^{-1} \mathbf{1})^{-1} \mathbf{1}^\top (XX^\top + KI_m)^{-1} y, \quad (*_{b_3})$$

as claimed. \square

In summary the KKT-equations determine both α and μ , and so $w = X^\top \alpha$ and b as well.

There is also a useful expression of b as an average.

Since $\mathbf{1}^\top \mathbf{1} = m$ and $\mathbf{1}^\top \alpha = 0$, we get

$$b = \frac{1}{m} \mathbf{1}^\top y - \frac{1}{m} \mathbf{1}^\top Xw - \frac{1}{m} K \mathbf{1}^\top \alpha = \bar{y} - \sum_{j=1}^n \overline{X^j} w_j,$$

where \bar{y} is the mean of y and $\overline{X^j}$ is the mean of the j th column of X . Therefore,

$$b = \bar{y} - \sum_{j=1}^n \overline{X^j} w_j = \bar{y} - (\overline{X^1} \cdots \overline{X^n}) w,$$

where $(\overline{X^1} \cdots \overline{X^n})$ is the $1 \times n$ row vector whose j th entry is $\overline{X^j}$.

We will now show that solving the dual **(DRR3)** for α and obtaining $w = X^\top \alpha$ is equivalent to solving our previous ridge regression Problem **(RR2)** applied to the centered data $\hat{y} = y - \bar{y}\mathbf{1}_m$ and $\hat{X} = X - \bar{X}$, where \bar{X} is the $m \times n$ matrix whose j th column is $\overline{X^j}\mathbf{1}_m$, the vector whose coordinates are all equal to the mean $\overline{X^j}$ of the j th column X^j of X .

The expression

$$b = \bar{y} - (\overline{X^1} \cdots \overline{X^n}) w$$

suggests looking for an intercept term b (also called bias) of the above form, namely

Program (RR4):

$$\begin{aligned} & \text{minimize } \xi^\top \xi + Kw^\top w \\ & \text{subject to} \\ & \quad y - Xw - b\mathbf{1} = \xi \\ & \quad b = \hat{b} + \bar{y} - (\overline{X^1} \cdots \overline{X^n}) w, \end{aligned}$$

with $\hat{b} \in \mathbb{R}$. Again, in Program **(RR4)**, minimization is performed over ξ , w , b and \hat{b} , but b and \hat{b} are not penalized.

Since

$$b\mathbf{1} = \hat{b}\mathbf{1} + \bar{y}\mathbf{1} - (\overline{X^1}\mathbf{1} \cdots \overline{X^n}\mathbf{1}) w,$$

if $\bar{X} = (\overline{X^1}\mathbf{1} \cdots \overline{X^n}\mathbf{1})$ is the $m \times n$ matrix whose j th column is the vector $\overline{X^j}\mathbf{1}$, then the above program is equivalent to the program

Program (RR5):

$$\begin{aligned} & \text{minimize } \xi^\top \xi + Kw^\top w \\ & \text{subject to} \\ & \quad y - Xw - \bar{y}\mathbf{1} + \bar{X}w - \hat{b}\mathbf{1} = \xi, \end{aligned}$$

where minimization is performed over ξ , w and \hat{b} . If we write $\hat{y} = y - \bar{y}\mathbf{1}$ and $\hat{X} = X - \bar{X}$, then the above program becomes

Program (RR6):

$$\begin{aligned} & \text{minimize } \xi^\top \xi + Kw^\top w \\ & \text{subject to} \\ & \quad \hat{y} - \hat{X}w - \hat{b}\mathbf{1} = \xi, \end{aligned}$$

minimizing over ξ, w and \hat{b} . If the solution to this program is \hat{w} , then \hat{b} is given by

$$\hat{b} = \bar{\hat{y}} - (\bar{\hat{X}}^1 \dots \bar{\hat{X}}^n) \hat{w} = 0,$$

since the data \hat{y} and \hat{X} are centered. Therefore **(RR6)** is equivalent to ridge regression without an intercept term applied to the centered data $\hat{y} = y - \bar{y}\mathbf{1}$ and $\hat{X} = X - \bar{X}$,

Program (RR6'):

$$\begin{aligned} & \text{minimize } \xi^\top \xi + K w^\top w \\ & \text{subject to} \\ & \quad \hat{y} - \hat{X} w = \xi, \end{aligned}$$

minimizing over ξ and w .

If \hat{w} is the optimal solution of this program given by

$$\hat{w} = \hat{X}^\top (\hat{X} \hat{X}^\top + K I_m)^{-1} \hat{y}, \quad (*_{w_6})$$

then b is given by

$$b = \bar{y} - (\bar{X}^1 \dots \bar{X}^n) \hat{w}.$$

Remark: Although this is not obvious a priori, the optimal solution w^* of the Program **(RR3)** given by $(*_{w_3})$ is equal to the optimal solution \hat{w} of Program **(RR6')** given by $(*_{w_6})$. We believe that it should be possible to prove the equivalence of these formulae but a proof eludes us at this time. We leave this as an open problem. In practice the Program **(RR6')** involving the centered data appears to be the preferred one.

Example 55.1. Consider the data set (X, y_1) with

$$X = \begin{pmatrix} -10 & 11 \\ -6 & 5 \\ -2 & 4 \\ 0 & 0 \\ 1 & 2 \\ 2 & -5 \\ 6 & -4 \\ 10 & -6 \end{pmatrix}, \quad y_1 = \begin{pmatrix} 0 \\ -2.5 \\ 0.5 \\ -2 \\ 2.5 \\ -4.2 \\ 1 \\ 4 \end{pmatrix}$$

as illustrated in Figure 55.1. We find that $\bar{y} = -0.0875$ and $(\bar{X}^1, \bar{X}^2) = (0.125, 0.875)$. For the value $K = 5$, we obtain

$$w = \begin{pmatrix} 0.9207 \\ 0.8677 \end{pmatrix}, \quad b = -0.9618,$$

for $K = 0.1$, we obtain

$$w = \begin{pmatrix} 1.1651 \\ 1.1341 \end{pmatrix}, \quad b = -1.2255,$$

and for $K = 0.01$,

$$w = \begin{pmatrix} 1.1709 \\ 1.1405 \end{pmatrix}, \quad b = -1.2318.$$

See Figure 55.2.

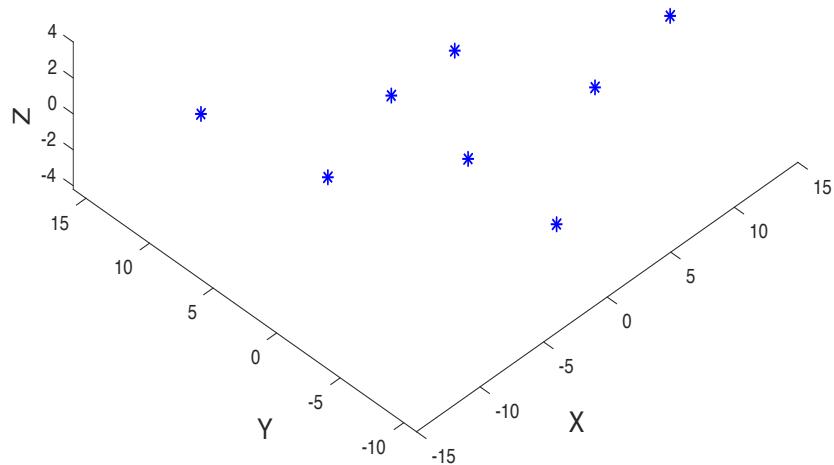

Figure 55.1: The data set (X, y_1) of Example 55.1.

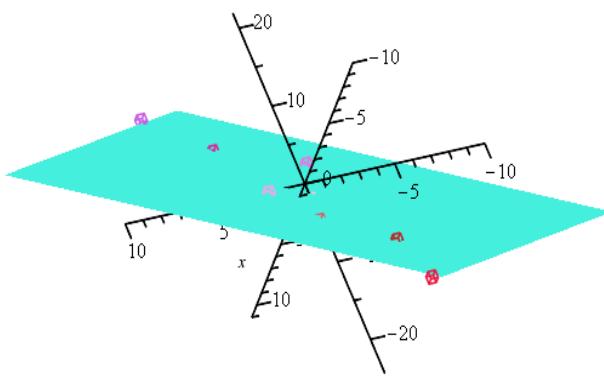

Figure 55.2: The graph of the plane $f(x, y) = 1.1709x + 1.1405y - 1.2318$ as an approximate fit to the data (X, y_1) of Example 55.1.

We conclude that the points (X_i, y_i) (where X_i is the i th row of X) almost lie on the plane of equation

$$x + y - z - 1 = 0,$$

and that f is almost the function given by $f(x, y) = 1.1x + 1.1y - 1.2$. See Figures 55.3 and 55.4.

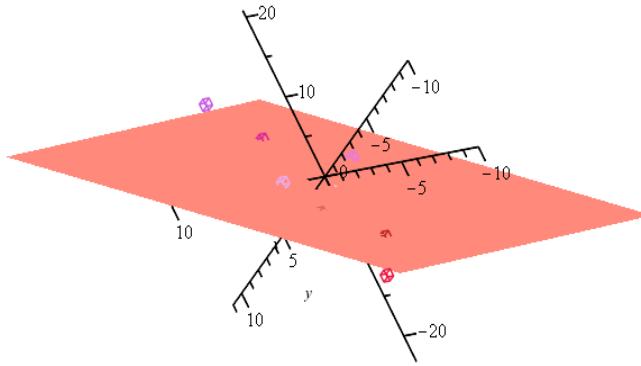

Figure 55.3: The graph of the plane $f(x, y) = 1.1x + 1.1y - 1.2$ as an approximate fit to the data (X, y_1) of Example 55.1.

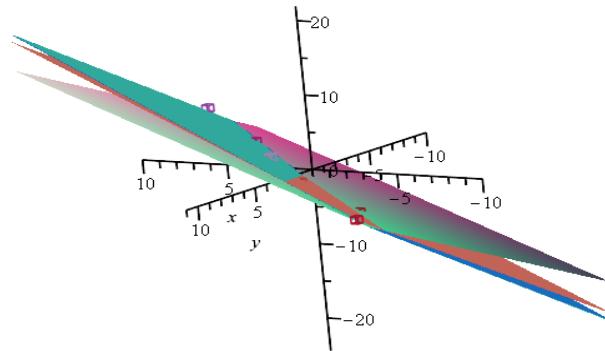

Figure 55.4: A comparison of how the graphs of the planes corresponding to $K = 1, 0.1, 0.01$ and the salmon plane of equation $f(x, y) = 1.1x + 1.1y - 1.2$ approximate the data (X, y_1) of Example 55.1.

If we change y_1 to

$$y_2 = (0 \ -2 \ 1 \ -1 \ 2 \ -4 \ 1 \ 3)^T,$$

as evidenced by Figure 55.5, the exact solution is

$$w = \begin{pmatrix} 1 \\ 1 \end{pmatrix}, \quad b = -1,$$

and for $K = 0.01$, we find that

$$w = \begin{pmatrix} 0.9999 \\ 0.9999 \end{pmatrix}, \quad b = -0.9999.$$

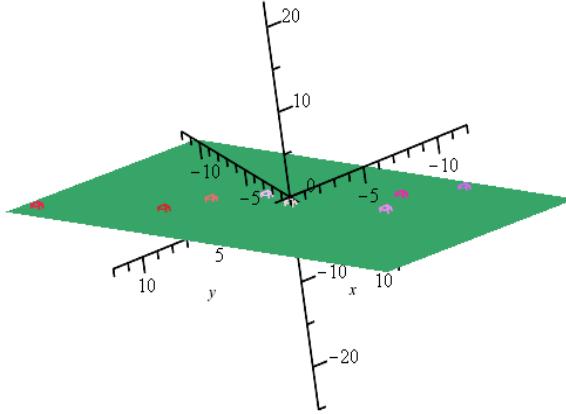

Figure 55.5: The data (X, y_2) of Example 55.1 is contained within the graph of the plane $f(x, y) = x + y - 1$.

We can see how the choice of K affects the quality of the solution (w, b) by computing the norm $\|\xi\|_2$ of the error vector $\xi = \hat{y} - \hat{X}w$. We notice that the smaller K is, the smaller is this norm.

It is natural to wonder what happens *if we also penalize b* in program (RR3). Let us add the term Kb^2 to the objective function. Then we obtain the program

$$\begin{aligned} & \text{minimize} \quad \xi^\top \xi + Kw^\top w + Kb^2 \\ & \text{subject to} \\ & \quad y - Xw - b\mathbf{1} = \xi, \end{aligned}$$

minimizing over ξ, w and b .

This suggests treating b as an extra component of the weight vector w and by forming the $m \times (n+1)$ matrix $[X \ \mathbf{1}]$ obtained by adding a column of 1's (of dimension m) to the matrix X , we obtain

Program (RR3b):

$$\begin{aligned} & \text{minimize} \quad \xi^\top \xi + Kw^\top w + Kb^2 \\ & \text{subject to} \end{aligned}$$

$$y - [X \ 1] \begin{pmatrix} w \\ b \end{pmatrix} = \xi,$$

minimizing over ξ, w and b .

This program is solved just as Program (RR2). In terms of the dual variable α , we get

$$\begin{aligned} \alpha &= ([X \ 1][X \ 1]^\top + KI_m)^{-1}y \\ \begin{pmatrix} w \\ b \end{pmatrix} &= [X \ 1]^\top \alpha \\ \xi &= K\alpha. \end{aligned}$$

Thus $b = \mathbf{1}^\top \alpha$. Observe that $[X \ 1][X \ 1]^\top = XX^\top + \mathbf{1}\mathbf{1}^\top$.

If $n < m$, it is preferable to use the formula

$$\begin{pmatrix} w \\ b \end{pmatrix} = ([X \ 1]^\top [X \ 1] + KI_{n+1})^{-1}[X \ 1]^\top y.$$

Since we also have the equation

$$y - Xw - b\mathbf{1} = \xi,$$

we obtain

$$\frac{1}{m}\mathbf{1}^\top y - \frac{1}{m}\mathbf{1}^\top Xw - \frac{1}{m}b\mathbf{1}^\top \mathbf{1} = \frac{1}{m}\mathbf{1}^\top K\alpha,$$

so

$$\bar{y} - (\bar{X}^1 \cdots \bar{X}^n)w - b = \frac{1}{m}Kb,$$

which yields

$$b = \frac{m}{m+K}(\bar{y} - (\bar{X}^1 \cdots \bar{X}^n)w).$$

Remark: As a least squares problem, the solution is given in terms of the pseudo-inverse $[X \ 1]^+$ of $[X \ 1]$ by

$$\begin{pmatrix} w \\ b \end{pmatrix} = [X \ 1]^+ y.$$

Example 55.2. Applying Program (RR3b) to the data set of Example 55.1 with $K = 0.01$ yields

$$w = \begin{pmatrix} 1.1706 \\ 1.1401 \end{pmatrix}, \quad b = -1.2298.$$

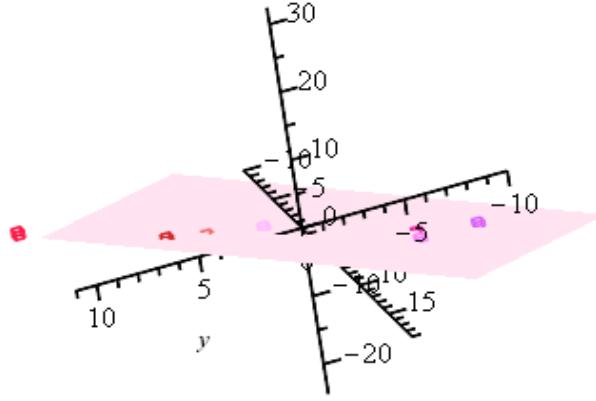

Figure 55.6: The graph of the plane $f(x, y) = 1.1706x + 1.1401y - 1.2298$ as an approximate fit to the data (X, y_1) of Example 55.1.

See Figure 55.6. We can see how the choice of K affects the quality of the solution (w, b) by computing the norm $\|\xi\|_2$ of the error vector $\xi = y - Xw - b\mathbf{1}_m$. As in Example 55.1 we notice that the smaller K is, the smaller is this norm. We also observe that for a given value of K , Program **(RR6')** gives a slightly smaller value of $\|\xi\|_2$ than **(RR3b)** does.

As pointed out by Hastie, Tibshirani, and Friedman [88] (Section 3.4), a defect of the approach where b is also penalized is that the solution for b is not invariant under adding a constant c to each value y_i . This is not the case for the approach using Program **(RR6')**.

55.3 Kernel Ridge Regression

One interesting aspect of the dual (of either **(RR2)** or **(RR3)**) is that it shows that the solution w being of the form $X^\top \alpha$, is a linear combination

$$w = \sum_{i=1}^m \alpha_i x_i$$

of the data points x_i , with the coefficients α_i corresponding to the dual variable $\lambda = 2K\alpha$ of the dual function, and with

$$\alpha = (XX^\top + KI_m)^{-1}y.$$

If m is smaller than n , then it is more advantageous to solve for α . But what really makes the dual interesting is that with our definition of X as

$$X = \begin{pmatrix} x_1^\top \\ \vdots \\ x_m^\top \end{pmatrix},$$

the matrix XX^\top consists of the inner products $x_i^\top x_j$, and similarly the function learned $f(x) = x^\top w$ can be expressed as

$$f(x) = \sum_{i=1}^m \alpha_i x_i^\top x,$$

namely that both w and $f(x)$ are given *in terms of the inner products* $x_i^\top x_j$ and $x_i^\top x$.

This fact is the key to a generalization to ridge regression in which the input space \mathbb{R}^n is embedded in a larger (possibly infinite dimensional) Euclidean space F (with an inner product $\langle -, - \rangle$) usually called a *feature space*, using a function

$$\varphi: \mathbb{R}^n \rightarrow F.$$

The problem becomes (*kernel ridge regression*)

Program (KRR2):

$$\begin{aligned} & \text{minimize} \quad \xi^\top \xi + K \langle w, w \rangle \\ & \text{subject to} \\ & \quad y_i - \langle w, \varphi(x_i) \rangle = \xi_i, \quad i = 1, \dots, m, \end{aligned}$$

minimizing over ξ and w . Note that $w \in F$. This problem is discussed in Shawe-Taylor and Christianini [159] (Section 7.3).

We will show below that the solution is exactly the same:

$$\begin{aligned} \alpha &= (\mathbf{G} + K I_m)^{-1} y \\ w &= \sum_{i=1}^m \alpha_i \varphi(x_i) \\ \xi &= K \alpha, \end{aligned}$$

where \mathbf{G} is the Gram matrix given by $\mathbf{G}_{ij} = \langle \varphi(x_i), \varphi(x_j) \rangle$. This matrix is also called the *kernel matrix* and is often denoted by \mathbf{K} instead of \mathbf{G} .

In this framework we have to be a little careful in using gradients since the inner product $\langle -, - \rangle$ on F is involved and F could be infinite dimensional, but this causes no problem because we can use derivatives, and by Proposition 39.5 we have

$$d\langle -, - \rangle_{(u,v)}(x, y) = \langle x, v \rangle + \langle u, y \rangle.$$

This implies that the derivative of the map $u \mapsto \langle u, u \rangle$ is

$$d\langle -, - \rangle_u(x) = 2\langle x, u \rangle. \tag{d_1}$$

Since the map $u \mapsto \langle u, v \rangle$ (with v fixed) is linear, its derivative is

$$d\langle -, v \rangle_u(x) = \langle x, v \rangle. \quad (d_2)$$

The derivative of the Lagrangian

$$L(\xi, w, \lambda) = \xi^\top \xi + K\langle w, w \rangle - \sum_{i=1}^m \lambda_i \langle \varphi(x_i), w \rangle - \xi^\top \lambda + \lambda^\top y$$

with respect to ξ and w is

$$dL_{\xi,w}(\tilde{\xi}, \tilde{w}) = 2(\tilde{\xi})^\top \xi - (\tilde{\xi})^\top \lambda + \left\langle 2Kw - \sum_{i=1}^m \lambda_i \varphi(x_i), \tilde{w} \right\rangle,$$

where we used (d_1) to calculate the derivative of $\xi^\top \xi + K\langle w, w \rangle$ and (d_2) to calculate the derivative of $-\sum_{i=1}^m \lambda_i \langle \varphi(x_i), w \rangle - \xi^\top \lambda$. We have $dL_{\xi,w}(\tilde{\xi}, \tilde{w}) = 0$ for all ξ and \tilde{w} iff

$$\begin{aligned} 2Kw &= \sum_{i=1}^m \lambda_i \varphi(x_i) \\ \lambda &= 2\xi. \end{aligned}$$

Again we define $\xi = K\alpha$, so we have $\lambda = 2K\alpha$, and

$$w = \sum_{i=1}^m \alpha_i \varphi(x_i).$$

Plugging back into the Lagrangian we get

$$\begin{aligned} G(\alpha) &= K^2 \alpha^\top \alpha + K \sum_{i,j=1}^m \alpha_i \alpha_j \langle \varphi(x_i), \varphi(x_j) \rangle - 2K \sum_{i,j=1}^m \alpha_i \alpha_j \langle \varphi(x_i), \varphi(x_j) \rangle \\ &\quad - 2K^2 \alpha^\top \alpha + 2K \alpha^\top y \\ &= -K^2 \alpha^\top \alpha - K \sum_{i,j=1}^m \alpha_i \alpha_j \langle \varphi(x_i), \varphi(x_j) \rangle + 2K \alpha^\top y. \end{aligned}$$

If \mathbf{G} is the matrix given by $\mathbf{G}_{ij} = \langle \varphi(x_i), \varphi(x_j) \rangle$, then we have

$$G(\alpha) = -K \alpha^\top (\mathbf{G} + K I_m) \alpha + 2K \alpha^\top y.$$

The function G is strictly concave, so by Theorem 40.13(4) it has a maximum for

$$\alpha = (\mathbf{G} + K I_m)^{-1} y,$$

as claimed earlier.

As in the standard case of ridge regression, if $F = \mathbb{R}^n$ (but the inner product $\langle -, - \rangle$ is arbitrary), we can adapt the above method to learn an affine function $f(w) = x^\top w + b$ instead of a linear function $f(w) = x^\top w$, where $b \in \mathbb{R}$. This time we assume that b is of the form

$$b = \bar{y} - \langle w, (\overline{X^1} \cdots \overline{X^n}) \rangle,$$

where X^j is the j column of the $m \times n$ matrix X whose i th row is the transpose of the column vector $\varphi(x_i)$, and where $(\overline{X^1} \cdots \overline{X^n})$ is viewed as a column vector. We have the minimization problem

Program (KRR6'):

$$\begin{aligned} & \text{minimize } \xi^\top \xi + K \langle w, w \rangle \\ & \text{subject to} \\ & \widehat{y}_i - \langle w, \widehat{\varphi(x_i)} \rangle = \xi_i, \quad i = 1, \dots, m, \end{aligned}$$

minimizing over ξ and w , where $\widehat{\varphi(x_i)}$ is the n -dimensional vector $\varphi(x_i) - (\overline{X^1} \cdots \overline{X^n})$.

The solution is given in terms of the matrix $\widehat{\mathbf{G}}$ defined by

$$\widehat{\mathbf{G}}_{ij} = \langle \widehat{\varphi(x_i)}, \widehat{\varphi(x_j)} \rangle,$$

as before. We get

$$\alpha = (\widehat{\mathbf{G}} + K I_m)^{-1} \widehat{y},$$

and according to a previous computation, b is given by

$$b = \bar{y} - \frac{1}{m} \mathbf{1}^\top \widehat{\mathbf{G}} \alpha.$$

We explained in Section 53.4 how to compute the matrix $\widehat{\mathbf{G}}$ from the matrix \mathbf{G} .

Since the dimension of the feature space F may be very large, one might worry that computing the inner products $\langle \varphi(x_i), \varphi(x_j) \rangle$ might be very expensive. This is where kernel functions come to the rescue. A *kernel function* κ for an embedding $\varphi: \mathbb{R}^n \rightarrow F$ is a map $\kappa: \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}$ with the property that

$$\kappa(u, v) = \langle \varphi(u), \varphi(v) \rangle \quad \text{for all } u, v \in \mathbb{R}^n.$$

If $\kappa(u, v)$ can be computed in a reasonably cheap way, and if $\varphi(u)$ can be computed cheaply, then the inner products $\langle \varphi(x_i), \varphi(x_j) \rangle$ (and $\langle \varphi(x_i), \varphi(x) \rangle$) can be computed cheaply; see Chapter 53. Fortunately there are good kernel functions. Two very good sources on kernel methods are Schölkopf and Smola [145] and Shawe-Taylor and Christianini [159].

55.4 Lasso Regression (ℓ^1 -Regularized Regression)

The main weakness of ridge regression is that the estimated weight vector w usually has many nonzero coefficients. As a consequence, ridge regression does not scale up well. In practice we need methods capable of handling millions of parameters, or more. A way to encourage sparsity of the vector w , which means that many coordinates of w are zero, is to replace the quadratic penalty function $\tau w^\top w = \tau \|w\|_2^2$ by the penalty function $\tau \|w\|_1$, with the ℓ^2 -norm replaced by the ℓ^1 -norm.

This method was first proposed by Tibshirani around 1996, under the name *lasso*, which stands for “least absolute selection and shrinkage operator.” This method is also known as ℓ^1 -regularized regression, but this is not as cute as “lasso,” which is used predominantly.

Given a set of training data $\{(x_1, y_1), \dots, (x_m, y_m)\}$, with $x_i \in \mathbb{R}^n$ and $y_i \in \mathbb{R}$, if X is the $m \times n$ matrix

$$X = \begin{pmatrix} x_1^\top \\ \vdots \\ x_m^\top \end{pmatrix},$$

in which the row vectors x_i^\top are the rows of X , then *lasso regression* is the following optimization problem

Program (lasso1):

$$\begin{aligned} & \text{minimize} \quad \frac{1}{2} \xi^\top \xi + \tau \|w\|_1 \\ & \text{subject to} \\ & \quad y - Xw = \xi, \end{aligned}$$

minimizing over ξ and w , where $\tau > 0$ is some constant determining the influence of the regularizing term $\|w\|_1$.

The difficulty with the regularizing term $\|w\|_1 = |w_1| + \dots + |w_n|$ is that the map $w \mapsto \|w\|_1$ is not differentiable for all w . This difficulty can be overcome by using subgradients, but the dual of the above program can also be obtained in an elementary fashion by using a trick that we already used, which is that if $x \in \mathbb{R}$, then

$$|x| = \max\{x, -x\}.$$

Using this trick, by introducing a vector $\epsilon \in \mathbb{R}^n$ of nonnegative variables, we can rewrite lasso minimization as follows:

Program lasso regularization (lasso2):

$$\text{minimize} \quad \frac{1}{2} \xi^\top \xi + \tau \mathbf{1}_n^\top \epsilon$$

subject to

$$y - Xw = \xi$$

$$w \leq \epsilon$$

$$-w \leq \epsilon.$$

minimizing over ξ, w and ϵ , with $y, \xi \in \mathbb{R}^m$, and $w, \epsilon, \mathbf{1}_n \in \mathbb{R}^n$.

The constraints $w \leq \epsilon$ and $-w \leq \epsilon$ are equivalent to $|w_i| \leq \epsilon_i$ for $i = 1, \dots, n$, so for an optimal solution we must have $\epsilon \geq 0$ and $|w_i| = \epsilon_i$, that is, $\|w\|_1 = \epsilon_1 + \dots + \epsilon_n$.

The Lagrangian $L(\xi, w, \epsilon, \lambda, \alpha_+, \alpha_-)$ is given by

$$\begin{aligned} L(\xi, w, \epsilon, \lambda, \alpha_+, \alpha_-) &= \frac{1}{2} \xi^\top \xi + \tau \mathbf{1}_n^\top \epsilon + \lambda^\top (y - Xw - \xi) \\ &\quad + \alpha_+^\top (w - \epsilon) + \alpha_-^\top (-w - \epsilon) \\ &= \frac{1}{2} \xi^\top \xi - \xi^\top \lambda + \lambda^\top y \\ &\quad + \epsilon^\top (\tau \mathbf{1}_n - \alpha_+ - \alpha_-) + w^\top (\alpha_+ - \alpha_- - X^\top \lambda), \end{aligned}$$

with $\lambda \in \mathbb{R}^m$ and $\alpha_+, \alpha_- \in \mathbb{R}_+^n$. Since the objective function is convex and the constraints are affine (and thus qualified), the Lagrangian L has a minimum with respect to the primal variables, ξ, w, ϵ iff $\nabla L_{\xi, w, \epsilon} = 0$. Since the gradient $\nabla L_{\xi, w, \epsilon}$ is given by

$$\nabla L_{\xi, w, \epsilon} = \begin{pmatrix} \xi - \lambda \\ \alpha_+ - \alpha_- - X^\top \lambda \\ \tau \mathbf{1}_n - \alpha_+ - \alpha_- \end{pmatrix},$$

we obtain the equations

$$\begin{aligned} \xi &= \lambda \\ \alpha_+ - \alpha_- &= X^\top \lambda \\ \alpha_+ + \alpha_- &= \tau \mathbf{1}_n. \end{aligned}$$

Using these equations, the dual function $G(\lambda, \alpha_+, \alpha_-) = \min_{\xi, w, \epsilon} L$ is given by

$$\begin{aligned} G(\lambda, \alpha_+, \alpha_-) &= \frac{1}{2} \xi^\top \xi - \xi^\top \lambda + \lambda^\top y = \frac{1}{2} \lambda^\top \lambda - \lambda^\top \lambda + \lambda^\top y \\ &= -\frac{1}{2} \lambda^\top \lambda + \lambda^\top y = -\frac{1}{2} (\|y - \lambda\|_2^2 - \|y\|_2^2), \end{aligned}$$

so

$$G(\lambda, \alpha_+, \alpha_-) = -\frac{1}{2} (\|y - \lambda\|_2^2 - \|y\|_2^2).$$

Since $\alpha_+, \alpha_- \geq 0$, for any $i \in \{1, \dots, n\}$ the minimum of $(\alpha_+)_i - (\alpha_-)_i$ is $-\tau$, and the maximum is τ . If we recall that for any $z \in \mathbb{R}^n$,

$$\|z\|_\infty = \max_{1 \leq i \leq n} |z_i|,$$

it follows that the constraints

$$\begin{aligned}\alpha_+ + \alpha_- &= \tau \mathbf{1}_n \\ X^\top \lambda &= \alpha_+ - \alpha_-\end{aligned}$$

are equivalent to

$$\|X^\top \lambda\|_\infty \leq \tau.$$

The above is equivalent to the $2n$ constraints

$$-\tau \leq (X^\top \lambda)_i \leq \tau, \quad 1 \leq i \leq n.$$

Therefore, the dual lasso program is given by

$$\begin{aligned}\text{maximize} \quad & -\frac{1}{2} (\|y - \lambda\|_2^2 - \|y\|_2^2) \\ \text{subject to} \quad & \|X^\top \lambda\|_\infty \leq \tau,\end{aligned}$$

which (since $\|y\|_2^2$ is a constant term) is equivalent to

Program (Dlasso2):

$$\begin{aligned}\text{minimize} \quad & \frac{1}{2} \|y - \lambda\|_2^2 \\ \text{subject to} \quad & \|X^\top \lambda\|_\infty \leq \tau,\end{aligned}$$

minimizing over $\lambda \in \mathbb{R}^m$.

One way to solve lasso regression is to use the dual program to find $\lambda = \xi$, and then to use linear programming to find w by solving the linear program arising from the lasso primal by holding ξ constant. The best way is to use ADMM as explained in Section 52.8(4). There are also a number of variations of gradient descent; see Hastie, Tibshirani, and Wainwright [89].

In theory, if we know the support of w and the signs of its components, then w is determined as we now explain.

In view of the constraint $y - Xw = \xi$ and the fact that for an optimal solution we must have $\xi = \lambda$, the following condition must hold:

$$\|X^\top(Xw - y)\|_\infty \leq \tau. \tag{*}$$

Also observe that for an optimal solution, we have

$$\begin{aligned} \frac{1}{2} \|y - Xw\|_2^2 + w^\top X^\top (y - Xw) &= \frac{1}{2} \|y\|^2 - w^\top X^\top y + \frac{1}{2} w^\top X^\top Xw + w^\top X^\top y - w^\top X^\top Xw \\ &= \frac{1}{2} (\|y\|_2^2 - \|Xw\|_2^2) \\ &= \frac{1}{2} (\|y\|_2^2 - \|y - \lambda\|_2^2) = G(\lambda). \end{aligned}$$

Since the objective function is convex and the constraints are qualified, by Theorem 50.19(2) the duality gap is zero, so for optimal solutions of the primal and the dual, $G(\lambda) = L(\xi, w, \epsilon)$, that is

$$\frac{1}{2} \|y - Xw\|_2^2 + w^\top X^\top (y - Xw) = \frac{1}{2} \|\xi\|_2^2 + \tau \|w\|_1 = \frac{1}{2} \|y - Xw\|_2^2 + \tau \|w\|_1,$$

which yields the equation

$$w^\top X^\top (y - Xw) = \tau \|w\|_1. \quad (**_1)$$

The above is the inner product of w and $X^\top (y - Xw)$, so whenever $w_i \neq 0$, since $\|w\|_1 = |w_1| + \dots + |w_n|$, in view of (*), we must have $(X^\top (y - Xw))_i = \tau \text{sgn}(w_i)$. If

$$S = \{i \in \{1, \dots, n\} \mid w_i \neq 0\}, \quad (\dagger)$$

if X_S denotes the matrix consisting of the columns of X indexed by S , and if w_S denotes the vector consisting of the nonzero components of w , then we have

$$X_S^\top (y - X_S w_S) = \tau \text{sgn}(w_S). \quad (**_2)$$

We also have

$$\|X_{\bar{S}}^\top (y - X_S w_S)\|_\infty \leq \tau, \quad (**_3)$$

where \bar{S} is the complement of S .

Equation $(**_2)$ yields

$$X_S^\top X_S w_S = X_S^\top y - \tau \text{sgn}(w_S),$$

so if $X_S^\top X_S$ is invertible (which will be the case if the columns of X are linearly independent), we get

$$w_S = (X_S^\top X_S)^{-1} (X_S^\top y - \tau \text{sgn}(w_S)). \quad (**_4)$$

In theory, if we know the support of w and the signs of its components, then w_S is determined, but in practice this is useless since the problem is to find the support and the sign of the solution.

55.5 Lasso Regression; Learning an Affine Function

In the preceding section we made the simplifying assumption that we were trying to learn a linear function $f(x) = x^\top w$. To learn an affine function $f(x) = x^\top w + b$, we solve the following optimization problem

Program (lasso3):

$$\begin{aligned} \text{minimize } & \frac{1}{2} \xi^\top \xi + \tau \mathbf{1}_n^\top \epsilon \\ \text{subject to } & y - Xw - b\mathbf{1}_m = \xi \\ & w \leq \epsilon \\ & -w \leq \epsilon. \end{aligned}$$

Observe that as in the case of ridge regression, minimization is performed over ξ , w , ϵ and b , but b is not penalized in the objective function.

The Lagrangian associated with this optimization problem is

$$\begin{aligned} L(\xi, w, \epsilon, b, \lambda, \alpha_+, \alpha_-) = & \frac{1}{2} \xi^\top \xi - \xi^\top \lambda + \lambda^\top y - b\mathbf{1}_m^\top \lambda \\ & + \epsilon^\top (\tau \mathbf{1}_n - \alpha_+ - \alpha_-) + w^\top (\alpha_+ - \alpha_- - X^\top \lambda), \end{aligned}$$

so by setting the gradient $\nabla L_{\xi, w, \epsilon, b}$ to zero we obtain the equations

$$\begin{aligned} \xi &= \lambda \\ \alpha_+ - \alpha_- &= X^\top \lambda \\ \alpha_+ + \alpha_- &= \tau \mathbf{1}_n \\ \mathbf{1}_m^\top \lambda &= 0. \end{aligned}$$

Using these equations, we find that the dual function is also given by

$$G(\lambda, \alpha_+, \alpha_-) = -\frac{1}{2} (\|y - \lambda\|_2^2 - \|y\|_2^2),$$

and the dual lasso program is given by

$$\begin{aligned} \text{maximize } & -\frac{1}{2} (\|y - \lambda\|_2^2 - \|y\|_2^2) \\ \text{subject to } & \|X^\top \lambda\|_\infty \leq \tau \\ & \mathbf{1}_m^\top \lambda = 0, \end{aligned}$$

which is equivalent to

Program (Dlasso3):

$$\begin{aligned} & \text{minimize} \quad \frac{1}{2} \|y - \lambda\|_2^2 \\ & \text{subject to} \\ & \quad \|X^\top \lambda\|_\infty \leq \tau \\ & \quad \mathbf{1}_m^\top \lambda = 0, \end{aligned}$$

minimizing over $\lambda \in \mathbb{R}^m$.

Once $\lambda = \xi$ and w are determined, we obtain b using the equation

$$b\mathbf{1}_m = y - Xw - \xi,$$

and since $\mathbf{1}_m^\top \mathbf{1}_m = m$ and $\mathbf{1}_m^\top \xi = \mathbf{1}_m^\top \lambda = 0$, the above yields

$$b = \frac{1}{m} \mathbf{1}_m^\top y - \frac{1}{m} \mathbf{1}_m^\top Xw - \frac{1}{m} \mathbf{1}_m^\top \xi = \bar{y} - \sum_{j=1}^n \bar{X}^j w_j,$$

where \bar{y} is the mean of y and \bar{X}^j is the mean of the j th column of X .

The equation

$$b = \hat{b} + \bar{y} - \sum_{j=1}^n \bar{X}^j w_j = \hat{b} + \bar{y} - (\bar{X}^1 \cdots \bar{X}^n)w,$$

can be used as in ridge regression, (see Section 55.2), to show that the Program (**lasso3**) is equivalent to applying lasso regression (**lasso2**) without an intercept term to the centered data, by replacing y by $\hat{y} = y - \bar{y}\mathbf{1}$ and X by $\hat{X} = X - \bar{X}$. Then b is given by

$$b = \bar{y} - (\bar{X}^1 \cdots \bar{X}^n)\hat{w},$$

where \hat{w} is the solution given by (**lasso2**). This is the method described by Hastie, Tibshirani, and Wainwright [89] (Section 2.2).

Example 55.3. We can create a data set (X, y) where X a 100×5 matrix and y is a 100×1 vector using the following Matlab program in which the command `randn` creates an array of normally distributed numbers.

```
X = randn(100,5);
ww = [0; 2; 0; -3; 0];
y = X*ww + randn(100,1)*0.1;
```

The purpose of the third line is to add some small noise to the “output” $X * ww$. The first five rows of X are

$$\begin{pmatrix} -1.1658 & -0.0679 & -1.6118 & 0.3199 & 0.4400 \\ -1.1480 & -0.1952 & -0.0245 & -0.5583 & -0.6169 \\ 0.1049 & -0.2176 & -1.9488 & -0.3114 & 0.2748 \\ 0.7223 & -0.3031 & 1.0205 & -0.5700 & 0.6011 \\ 2.5855 & 0.0230 & 0.8617 & -1.0257 & 0.0923 \end{pmatrix},$$

and the first five rows of y are

$$y = \begin{pmatrix} -1.0965 \\ 1.2155 \\ 0.4324 \\ 1.1902 \\ 3.1346 \end{pmatrix}.$$

We ran the program for lasso using ADMM (see Problem 52.7) with various values of ρ and τ , including $\rho = 1$ and $\rho = 10$. We observed that the program converges a lot faster for $\rho = 10$ than for $\rho = 1$. We plotted the values of the five components of $w(\tau)$ for values of τ from $\tau = 0$ to $\tau = 0.5$ by increment of 0.02, and observed that the first, third, and fifth coordinate drop basically linearly to zero (a value less than 10^{-4}) around $\tau = 0.2$. See Figures 55.7, 55.8, and 55.9. This behavior is also observed in Hastie, Tibshirani, and Wainwright [89] (Section 2.2).

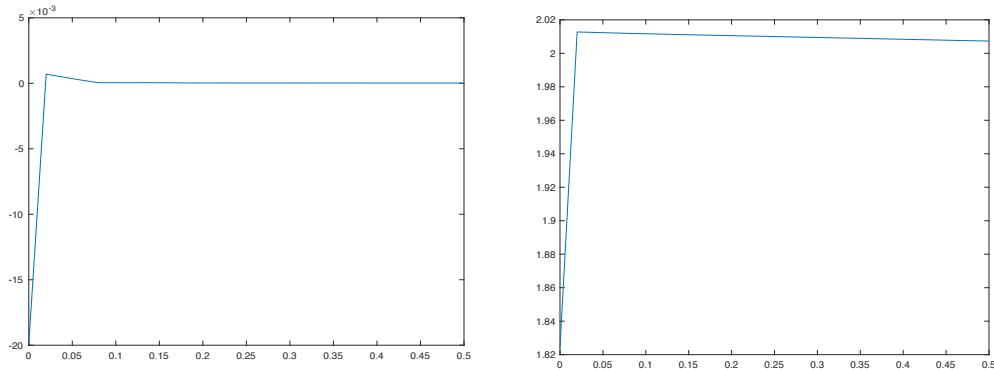

Figure 55.7: First and second component of w .

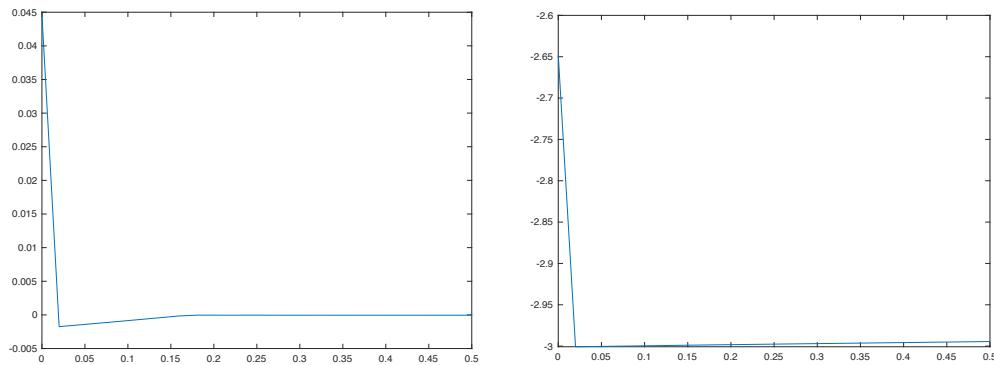

Figure 55.8: Third and fourth component of w .

For $\tau = 0.02$, we have

$$w = \begin{pmatrix} 0.00003 \\ 2.01056 \\ -0.00004 \\ -2.99821 \\ 0.00000 \end{pmatrix}, \quad b = 0.00135.$$

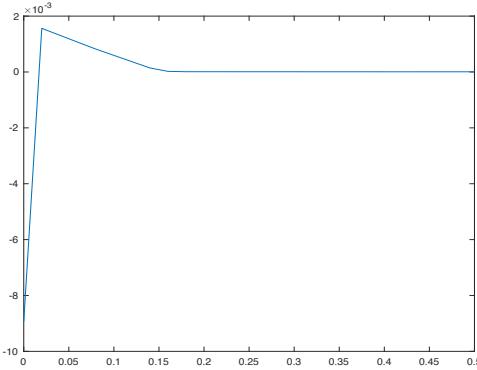

Figure 55.9: Fifth component of w .

This weight vector w is very close to the original vector $ww = [0; 2; 0; -3; 0]$ that we used to create y . For large values of τ , the weight vector is essentially the zero vector. This happens for $\tau = 235$, where every component of w is less than 10^{-5} .

Another way to find b is to add the term $(C/2)b^2$ to the objective function, for some positive constant C , obtaining the program

Program(lasso4):

$$\text{minimize } \frac{1}{2}\xi^\top\xi + \tau\mathbf{1}_n^\top\epsilon + \frac{1}{2}Cb^2$$

subject to

$$\begin{aligned} y - Xw - b\mathbf{1}_m &= \xi \\ w &\leq \epsilon \\ -w &\leq \epsilon, \end{aligned}$$

minimizing over ξ, w, ϵ and b .

This time the Lagrangian is

$$\begin{aligned} L(\xi, w, \epsilon, b, \lambda, \alpha_+, \alpha_-) &= \frac{1}{2}\xi^\top\xi - \xi^\top\lambda + \lambda^\top y + \frac{C}{2}b^2 - b\mathbf{1}_m^\top\lambda \\ &\quad + \epsilon^\top(\tau\mathbf{1}_n - \alpha_+ - \alpha_-) + w^\top(\alpha_+ - \alpha_- - X^\top\lambda), \end{aligned}$$

so by setting the gradient $\nabla L_{\xi,w,\epsilon,b}$ to zero we obtain the equations

$$\begin{aligned}\xi &= \lambda \\ \alpha_+ - \alpha_- &= X^\top \lambda \\ \alpha_+ + \alpha_- &= \tau \mathbf{1}_n \\ Cb &= \mathbf{1}_m^\top \lambda.\end{aligned}$$

Thus b is also determined, and the dual lasso program is identical to the first lasso dual (**Dlasso2**), namely

$$\begin{aligned}\text{minimize } & \frac{1}{2} \|y - \lambda\|_2^2 \\ \text{subject to } & \|X^\top \lambda\|_\infty \leq \tau,\end{aligned}$$

minimizing over λ .

Since the equations $\xi = \lambda$ and

$$y - Xw - b\mathbf{1}_m = \xi$$

hold, from $Cb = \mathbf{1}_m^\top \lambda$ we get

$$\frac{1}{m} \mathbf{1}_m^\top y - \frac{1}{m} \mathbf{1}_m^\top Xw - b \frac{1}{m} \mathbf{1}_m^\top \mathbf{1} = \frac{1}{m} \mathbf{1}_m^\top \lambda,$$

that is

$$\bar{y} - (\bar{X}^1 \cdots \bar{X}^n)w - b = \frac{C}{m}b,$$

which yields

$$b = \frac{m}{m+C}(\bar{y} - (\bar{X}^1 \cdots \bar{X}^n)w).$$

As in the case of ridge regression, a defect of the approach where b is also penalized is that the solution for b is not invariant under adding a constant c to each value y_i

It is interesting to compare the behavior of the methods:

1. Ridge regression (**RR6'**) (which is equivalent to (**RR3**)).
2. Ridge regression (**RR3b**), with b penalized (by adding the term Kb^2 to the objective function).
3. Least squares applied to $[X \ \mathbf{1}]$.
4. (**lasso3**).

When $n \leq 2$ and K and τ are small and of the same order of magnitude, say 0.1 or 0.01, there is no noticeable difference. We ran out programs on the data set of 200 points generated by the following Matlab program:

```
X14 = 15*randn(200,1);
ww14 = 1;
y14 = X14*ww14 + 10*randn(200,1) + 20;
```

The result is shown in Figure 55.10, with the following colors: Method (1) in magenta, Method (2) in red, Method (3) in blue, and Method (4) in cyan. All four lines are identical.

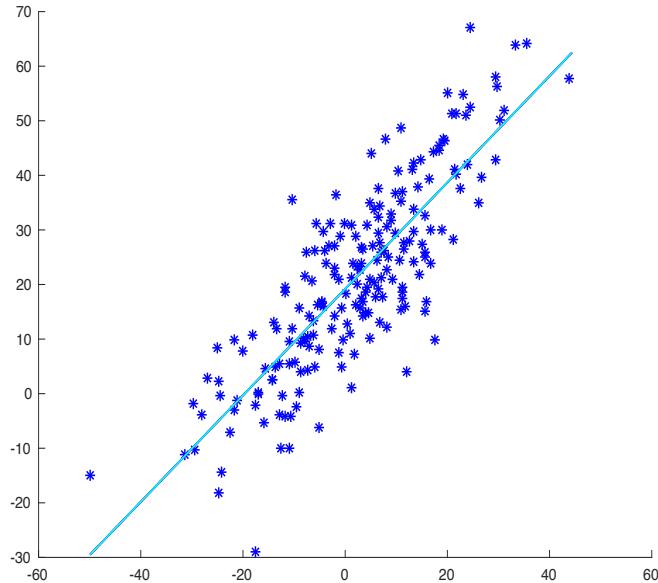

Figure 55.10: Comparison of the four methods with $K = \tau = 0.1$.

In order to see a difference we also ran our programs with $K = 1000$ and $\tau = 10000$; see Figure 55.11.

As expected, due to the penalization of b , Method (3) yields a significantly lower line (in red), and due to the large value of τ , the line corresponding to lasso (in cyan) has a smaller slope. Method (1) (in magenta) also has a smaller slope but still does not deviate that much from least squares (in blue). It is also interesting to experiment on data sets where n is larger (say 20, 50).

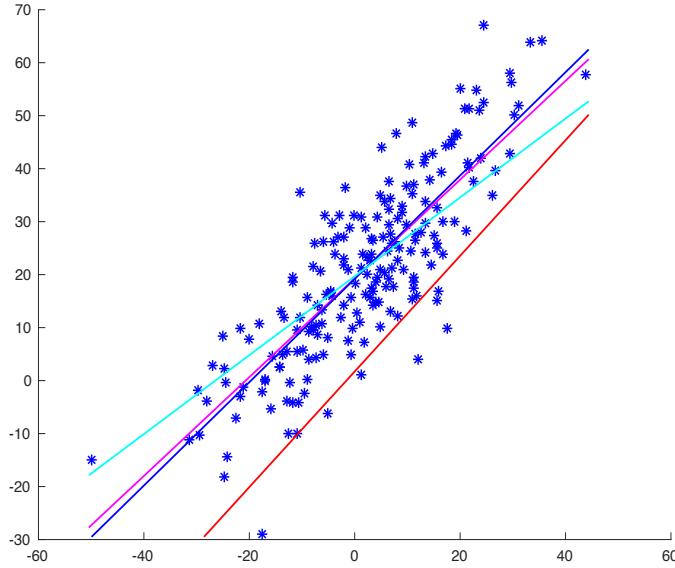

Figure 55.11: Comparison of the four methods with $K = 1000, \tau = 10000$.

55.6 Elastic Net Regression

The lasso method is unsatisfactory when n (the dimension of the data) is much larger than the number m of data, because it only selects m coordinates and sets the others to values close to zero. It also has problems with groups of highly correlated variables. A way to overcome this problem is to add a “ridge-like” term $(1/2)Kw^\top w$ to the objective function. This way we obtain a hybrid of lasso and ridge regression called the *elastic net method* and defined as follows:

Program (elastic net):

$$\begin{aligned} & \text{minimize} \quad \frac{1}{2}\xi^\top \xi + \frac{1}{2}Kw^\top w + \tau \mathbf{1}_n^\top \epsilon \\ & \text{subject to} \\ & \quad y - Xw - b\mathbf{1}_m = \xi \\ & \quad w \leq \epsilon \\ & \quad -w \leq \epsilon, \end{aligned}$$

where $K > 0$ and $\tau \geq 0$ are two constants controlling the influence of the ℓ^2 -regularization and the ℓ^1 -regularization.¹ Observe that as in the case of ridge regression, minimization is performed over ξ , w , ϵ and b , but b is not penalized in the objective function. The objective

¹Some of the literature denotes K by λ_2 and τ by λ_1 , but we prefer not to adopt this notation since we use λ, μ etc. to denote Lagrange multipliers.

function is strictly convex so if an optimal solution exists, then it is unique; the proof is left as an exercise.

The Lagrangian associated with this optimization problem is

$$\begin{aligned} L(\xi, w, \epsilon, b, \lambda, \alpha_+, \alpha_-) &= \frac{1}{2}\xi^\top \xi - \xi^\top \lambda + \lambda^\top y - b\mathbf{1}_m^\top \lambda \\ &\quad + \epsilon^\top (\tau\mathbf{1}_n - \alpha_+ - \alpha_-) + w^\top (\alpha_+ - \alpha_- - X^\top \lambda) + \frac{1}{2}Kw^\top w, \end{aligned}$$

so by setting the gradient $\nabla L_{\xi, w, \epsilon, b}$ to zero we obtain the equations

$$\begin{aligned} \xi &= \lambda \\ Kw &= -(\alpha_+ - \alpha_- - X^\top \lambda) \\ \alpha_+ + \alpha_- - \tau\mathbf{1}_n &= 0 \\ \mathbf{1}_m^\top \lambda &= 0. \end{aligned} \tag{*}_w$$

We find that $(*_w)$ determines w . Using these equations, we can find the dual function but in order to solve the dual using ADMM, since $\lambda \in \mathbb{R}^m$, it is more convenient to write $\lambda = \lambda_+ - \lambda_-$, with $\lambda_+, \lambda_- \in \mathbb{R}_+^m$ (recall that $\alpha_+, \alpha_- \in \mathbb{R}_+^n$). As in the derivation of the dual of ridge regression, we rescale our variables by defining $\beta_+, \beta_-, \mu_+, \mu_-$ such that

$$\alpha_+ = K\beta_+, \quad \alpha_- = K\beta_-, \quad \lambda_+ = K\mu_+, \quad \lambda_- = K\mu_-.$$

We also let $\mu = \mu_+ - \mu_-$ so that $\lambda = K\mu$. Then $\mathbf{1}_m^\top \lambda = 0$ is equivalent to

$$\mathbf{1}_m^\top \mu_+ - \mathbf{1}_m^\top \mu_- = 0,$$

and since $\xi = \lambda = K\mu$, we have

$$\begin{aligned} \xi &= K(\mu_+ - \mu_-) \\ \beta_+ + \beta_- &= \frac{\tau}{K}\mathbf{1}_n. \end{aligned}$$

Using $(*_w)$ we can write

$$\begin{aligned} w &= -(\beta_+ - \beta_- - X^\top \mu) = -\beta_+ + \beta_- + X^\top \mu_+ - X^\top \mu_- \\ &= (-I_n \quad I_n \quad X^\top \quad -X^\top) \begin{pmatrix} \beta_+ \\ \beta_- \\ \mu_+ \\ \mu_- \end{pmatrix}. \end{aligned}$$

Then we have

$$\begin{aligned} \begin{pmatrix} -I_n & I_n & X^\top & -X^\top \end{pmatrix}^\top \begin{pmatrix} -I_n & I_n & X^\top & -X^\top \end{pmatrix} &= \begin{pmatrix} -I_n \\ I_n \\ X \\ -X \end{pmatrix} \begin{pmatrix} -I_n & I_n & X^\top & -X^\top \end{pmatrix} \\ &= \begin{pmatrix} I_n & -I_n & -X^\top & X^\top \\ -I_n & I_n & X^\top & -X^\top \\ -X & X & XX^\top & -XX^\top \\ X & -X & -XX^\top & XX^\top \end{pmatrix}. \end{aligned}$$

If we define the symmetric positive semidefinite $2(n+m) \times 2(n+m)$ matrix Q as

$$Q = \begin{pmatrix} I_n & -I_n & -X^\top & X^\top \\ -I_n & I_n & X^\top & -X^\top \\ -X & X & XX^\top & -XX^\top \\ X & -X & -XX^\top & XX^\top \end{pmatrix},$$

then

$$\frac{1}{2}w^\top w = \frac{1}{2}(\beta_+^\top \ \beta_-^\top \ \mu_+^\top \ \mu_-^\top) Q \begin{pmatrix} \beta_+ \\ \beta_- \\ \mu_+ \\ \mu_- \end{pmatrix}.$$

As a consequence, using $(*_w)$ and the fact that $\xi = K\mu$, we find that the dual function is given by

$$\begin{aligned} G(\mu, \beta_+, \beta_-) &= \frac{1}{2}\xi^\top \xi - \xi^\top \lambda + \lambda^\top y + w^\top (\alpha_+ - \alpha_- - X^\top \lambda) + \frac{1}{2}Kw^\top w \\ &= \frac{1}{2}\xi^\top \xi - K\xi^\top \mu + K\mu^\top y + Kw^\top (\beta_+ - \beta_- - X^\top \mu) + \frac{1}{2}Kw^\top w \\ &= \frac{1}{2}K^2\mu^\top \mu - K^2\mu^\top \mu + Ky^\top \mu - Kw^\top w + \frac{1}{2}Kw^\top w \\ &= -\frac{1}{2}K^2\mu^\top \mu - \frac{1}{2}Kw^\top w + Ky^\top \mu. \end{aligned}$$

But

$$\mu = (I_m \ -I_m) \begin{pmatrix} \mu_+ \\ \mu_- \end{pmatrix},$$

so

$$\frac{1}{2}\mu^\top \mu = \frac{1}{2}(\mu_+^\top \ \mu_-^\top) \begin{pmatrix} I_m & -I_m \\ -I_m & I_m \end{pmatrix} \begin{pmatrix} \mu_+ \\ \mu_- \end{pmatrix},$$

so we get

$$G(\beta_+, \beta_-, \mu_+, \mu_-) = -\frac{1}{2}K \begin{pmatrix} \beta_+^\top & \beta_-^\top & \mu_+^\top & \mu_-^\top \end{pmatrix} P \begin{pmatrix} \beta_+ \\ \beta_- \\ \mu_+ \\ \mu_- \end{pmatrix} - Kq^\top \begin{pmatrix} \beta_+ \\ \beta_- \\ \mu_+ \\ \mu_- \end{pmatrix}$$

with

$$\begin{aligned} P &= Q + K \begin{pmatrix} 0_{n,n} & 0_{n,n} & 0_{n,m} & 0_{n,m} \\ 0_{n,n} & 0_{n,n} & 0_{n,m} & 0_{n,m} \\ 0_{m,n} & 0_{m,n} & I_m & -I_m \\ 0_{m,n} & 0_{m,n} & -I_m & I_m \end{pmatrix} \\ &= \begin{pmatrix} I_n & -I_n & -X^\top & X^\top \\ -I_n & I_n & X^\top & -X^\top \\ -X & X & XX^\top + KI_m & -XX^\top - KI_m \\ X & -X & -XX^\top - KI_m & XX^\top + KI_m \end{pmatrix}, \end{aligned}$$

and

$$q = \begin{pmatrix} 0_n \\ 0_n \\ -y \\ y \end{pmatrix}.$$

The constraints are the equations

$$\begin{aligned} \beta_+ + \beta_- &= \frac{\tau}{K} \mathbf{1}_n \\ \mathbf{1}_m^\top \mu_+ - \mathbf{1}_m^\top \mu_- &= 0, \end{aligned}$$

which correspond to the $(n+1) \times 2(n+m)$ matrix

$$A = \begin{pmatrix} I_n & I_n & 0_{n,m} & 0_{n,m} \\ 0_n^\top & 0_n^\top & \mathbf{1}_m^\top & -\mathbf{1}_m^\top \end{pmatrix}$$

and the right-hand side

$$c = \begin{pmatrix} \frac{\tau}{K} \mathbf{1}_n \\ 0 \end{pmatrix}.$$

Since $K > 0$, the dual of elastic net is equivalent to

Program (Dual Elastic Net):

$$\text{minimize} \quad \frac{1}{2} (\beta_+^\top \quad \beta_-^\top \quad \mu_+^\top \quad \mu_-^\top) P \begin{pmatrix} \beta_+ \\ \beta_- \\ \mu_+ \\ \mu_- \end{pmatrix} + q^\top \begin{pmatrix} \beta_+ \\ \beta_- \\ \mu_+ \\ \mu_- \end{pmatrix}$$

subject to

$$A \begin{pmatrix} \beta_+ \\ \beta_- \\ \mu_+ \\ \mu_- \end{pmatrix} = c,$$

$$\beta_+, \beta_- \in \mathbb{R}_+^n, \mu_+, \mu_- \in \mathbb{R}_+^m.$$

Once $\xi = K\mu = K(\mu_+ - \mu_-)$ and w are determined by $(*_w)$, we obtain b using the equation

$$b\mathbf{1}_m = y - Xw - \xi,$$

which as in Section 55.5 yields

$$b = \bar{y} - \sum_{j=1}^n \overline{X^j} w_j,$$

where \bar{y} is the mean of y and $\overline{X^j}$ is the mean of the j th column of X .

We leave it as an easy exercise to show that A has rank $n + 1$. Then we can solve the above program using ADMM, and we have done so. This very similar to what is done in Section 56.3, and hence the details are left as an exercise.

Observe that when $\tau = 0$, the elastic net method reduces to ridge regression. As K tends to 0 the elastic net method tends to lasso, but $K = 0$ is not an allowable value since $\tau/0$ is undefined. Anyway, if we get rid of the constraint

$$\beta_+ + \beta_- = \frac{\tau}{K} \mathbf{1}_n$$

the corresponding optimization program not does determine w . Experimenting with our program we found that convergence becomes very slow for $K < 10^{-3}$. What we can do if K is small, say $K < 10^{-3}$, is to run lasso. A nice way to “blend” ridge regression and lasso is to call the elastic net method with $K = C(1 - \theta)$ and $\tau = C\theta$, where $0 \leq \theta < 1$ and $C > 0$.

Running the elastic net method on the data set $(X14, y14)$ of Section 55.5 with $K = \tau = 0.5$ shows absolutely no difference, but the reader should conduct more experiments to see how elastic net behaves as K and τ are varied (the best way to do this is to use θ as explained above). Here is an example involving a data set $(X20, y20)$ where $X20$ is a 200×30 matrix generated as follows:

```
X20 = randn(50,30);
ww20 = [0; 2; 0; -3; 0; -4; 1; 0; 2; 0; 2; 3; 0; -5; 6; 0; 1; 2; 0; 10;
0; 0; 3; 4; 5; 0; 0; -6; -8; 0];
y20 = X20*ww20 + randn(50,1)*0.1 + 5;
```

Running our program with $K = 0.01$ and $K = 0.99$, and then with $K = 0.99$ and $K = 0.01$, we get the following weight vectors (in the left column is the weight vector corresponding to $K = 0.01$ and $K = 0.99$):

0.0254	0.2007
1.9193	2.0055
0.0766	0.0262
-3.0014	-2.8008
0.0512	0.0089
-3.8815	-3.7670
0.9591	0.8552
-0.0086	-0.3243
1.9576	1.9080
-0.0077	-0.1041
1.9881	2.0566
2.9223	2.8346
-0.0046	-0.0832
-4.9989	-4.8332
5.8640	5.4598
-0.0207	-0.2141
0.8285	0.8585
1.9310	1.8559
0.0046	0.0413
9.9232	9.4836
-0.0216	0.0303
0.0453	-0.0193
2.9384	3.0004
4.0525	3.9753
4.8723	4.6530
0.0767	0.1192
0.0132	-0.0203
-5.9750	-5.7537
-7.9764	-7.7594
-0.0054	0.0528

Generally, the numbers in the left column, which are more “lasso-like,” have clearer zeros and nonzero values closer to those of the weight vector $ww20$ that was used to create the data set. The value of b corresponding to the first call is $b = 5.1372$, and the value of b corresponding to the second call is $b = 5.208$.

We have observed that lasso seems to converge much faster than elastic net when $K < 10^{-3}$. For example, running the above data set with $K = 10^{-3}$ and $\tau = 0.999$ requires 140520 steps to achieve primal and dual residuals less than 10^{-7} , but lasso only takes 86 steps to achieve the same degree of convergence. We observed that the larger K is the faster is the convergence. This could be attributed to the fact that the matrix P becomes more “positive definite.” Another factor is that ADMM for lasso solves an $n \times n$ linear system, but ADMM for elastic net solves a $2(n + m) \times 2(n + m)$ linear system. So even though elastic net does not suffer from some of the undesirable properties of ridge regression and lasso, it appears to have a slower convergence rate, in fact much slower when K is small (say $K < 10^{-3}$). It also appears that elastic net may be too expensive a choice if m is much larger than n . Further investigations are required to gain a better understanding of the convergence issue.

55.7 Summary

The main concepts and results of this chapter are listed below:

- Ridge regression.
- Kernel ridge regression.
- Kernel functions.
- Lasso regression.
- Elastic net regression.

55.8 Problems

Problem 55.1. Check the formula

$$(X^\top X + KI_n)^{-1} X^\top = X^\top (X X^\top + KI_m)^{-1},$$

stated in Section 55.1.

Problem 55.2. Implement the ridge regression method described in Section 55.1 in Matlab. Also implement ridge regression with intercept and compare solving Program **(DRR3)** and Program **(RR6')** using centered data.

Problem 55.3. Implement the ridge regression with intercept method **(RR3b)** in Matlab and compare it with solving **(RR6')** using centered data.

Problem 55.4. Verify that **(lasso3)** is equivalent to **(lasso2)** applied to the centered data $\hat{y} = y - \bar{y}\mathbf{1}$ and $\hat{X} = X - \bar{X}$.

Problem 55.5. Verify the fomulae obtained for the kernel ridge regression program **(KRR6')**.

Problem 55.6. Implement in Matlab and test (**lasso3**) for various values of ρ and τ . Write a program to plot the coordinates of w as a function of τ . Compare the behavior of lasso with ridge regression (**RR6'**), (**RR3b**) (b penalized), and with least squares.

Problem 55.7. Check the details of the derivation of the dual of elastic net.

Problem 55.8. Write a Matlab program, solving the dual of elastic net; use inspiration from Section 56.3. Run tests to compare the behavior of ridge regression, lasso, and elastic net.

Problem 55.9. Prove that if an optimal solution exists for the elastic net method, then it is unique.

Problem 55.10. Prove that the matrix

$$P = \begin{pmatrix} I_n & -I_n & -X^\top & X^\top \\ -I_n & I_n & X^\top & -X^\top \\ -X & X & XX^\top + KI_m & -XX^\top - KI_m \\ X & -X & -XX^\top - KI_m & XX^\top + KI_m \end{pmatrix}$$

is almost positive definite, in the sense that

$$\begin{pmatrix} \beta_+^\top & \beta_-^\top & \mu_+^\top & \mu_-^\top \end{pmatrix} P \begin{pmatrix} \beta_+ \\ \beta_- \\ \mu_+ \\ \mu_- \end{pmatrix} = 0$$

if and only if $\beta_+ = \beta_-$ and $\mu_+ = \mu_-$, that is, $\beta = 0$ and $\mu = 0$.

Chapter 56

ν -SV Regression

56.1 ν -SV Regression; Derivation of the Dual

Let $\{(x_1, y_1), \dots, (x_m, y_m)\}$ be a set of observed data usually called a set of *training data*, with $x_i \in \mathbb{R}^n$ and $y_i \in \mathbb{R}$. As in Chapter 55, we form the $m \times n$ matrix X where the row vectors x_i^\top are the *rows* of X . Our goal is to learn an affine function f of the form $f(x) = x^\top w + b$ that fits the set of training data, but does not penalize errors below some given $\epsilon \geq 0$. Geometrically, we view the pairs (x_i, y_i) as points in \mathbb{R}^{n+1} , and we try to fit a hyperplane $H_{w,b}$ of equation

$$(w^\top - 1) \begin{pmatrix} x \\ z \end{pmatrix} + b = w^\top x - z + b = 0$$

that best fits the set of points (x_i, y_i) (where $(x, z) \in \mathbb{R}^{n+1}$). We seek an $\epsilon > 0$ such that most points (x_i, y_i) are inside the slab (or tube) of width 2ϵ bounded by the hyperplane $H_{w,b-\epsilon}$ of equation

$$(w^\top - 1) \begin{pmatrix} x \\ z \end{pmatrix} + b - \epsilon = w^\top x - z + b - \epsilon = 0$$

and the hyperplane $H_{w,b+\epsilon}$ of equation

$$(w^\top - 1) \begin{pmatrix} x \\ z \end{pmatrix} + b + \epsilon = w^\top x - z + b + \epsilon = 0.$$

Observe that the hyperplanes $H_{w,b-\epsilon}$, $H_{w,b}$ and $H_{w,b+\epsilon}$ intersect the z -axis when $x = 0$ for the values $(b - \epsilon, b, b + \epsilon)$. Since $\epsilon \geq 0$, the hyperplane $H_{w,b-\epsilon}$ is below the hyperplane $H_{w,b}$ which is below the hyperplane $H_{w,b+\epsilon}$. We refer to the lower hyperplane $H_{w,b-\epsilon}$ as the *blue margin*, to the upper hyperplane $H_{w,b+\epsilon}$ as the *red margin*, and to the hyperplane $H_{w,b}$ as the *best fit hyperplane*. Also note that since the term $-z$ appears in the equations of these hyperplanes, points for which $w^\top x - z + b \leq 0$ are *above* the hyperplane $H_{w,b}$, and points for which $w^\top x - z + b \geq 0$ are *below* the hyperplane $H_{w,b}$ (and similarly for $H_{w,b-\epsilon}$ and

$H_{b+\epsilon}$). The region bounded by the hyperplanes $H_{w,b-\epsilon}$ and $H_{b+\epsilon}$ (which contains the best fit hyperplane $H_{w,b}$) is called the ϵ -slab.

We also allow *errors* by allowing the point (x_i, y_i) to be outside of the ϵ -slab but in the slab between the hyperplane $H_{w,b-\epsilon-\xi_i}$ of equation

$$(w^\top - 1) \begin{pmatrix} x \\ z \end{pmatrix} + b - \epsilon - \xi_i = w^\top x - z + b - \epsilon - \xi_i = 0$$

for some $\xi_i > 0$ (which is below the blue margin hyperplane $H_{w,b-\epsilon}$) and the hyperplane $H_{w,b+\epsilon+\xi'_i}$ of equation

$$(w^\top - 1) \begin{pmatrix} x \\ z \end{pmatrix} + b + \epsilon + \xi'_i = w^\top x_i - z + b + \epsilon + \xi'_i = 0$$

for some $\xi'_i > 0$ (which is above the red margin hyperplane $H_{w,b+\epsilon}$), so that $w^\top x_i - y_i + b - \epsilon - \xi_i \leq 0$ and $w^\top x_i - y_i + b + \epsilon + \xi'_i \geq 0$, that is,

$$\begin{aligned} f(x) - y_i &= w^\top x_i + b - y_i \leq \epsilon + \xi_i, \\ -(f(x) - y_i) &= -w^\top x_i - b + y_i \leq \epsilon + \xi'_i. \end{aligned}$$

Our goal is to minimize ϵ and the errors ξ_i and ξ'_i . See Figure 56.1. The trade off between

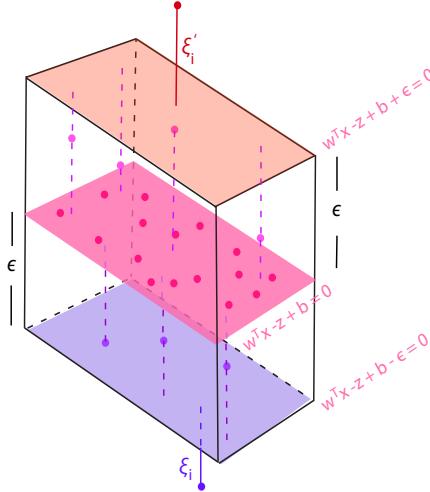

Figure 56.1: The ϵ -slab around the graph of the best fit affine function $f(x) = x^\top w + b$.

the size of ϵ and the size of the slack variables ξ_i and ξ'_i is achieved by using two constants $\nu \geq 0$ and $C > 0$. The method of ν -support vector regression, for short ν -SV regression, is specified by the following minimization problem:

Program ν -SV Regression:

$$\text{minimize} \quad \frac{1}{2} w^\top w + C \left(\nu \epsilon + \frac{1}{m} \sum_{i=1}^m (\xi_i + \xi'_i) \right)$$

subject to

$$\begin{aligned} w^\top x_i + b - y_i &\leq \epsilon + \xi_i, \quad \xi_i \geq 0 \quad i = 1, \dots, m \\ -w^\top x_i - b + y_i &\leq \epsilon + \xi'_i, \quad \xi'_i \geq 0 \quad i = 1, \dots, m \\ \epsilon &\geq 0, \end{aligned}$$

minimizing over the variables w, b, ϵ, ξ , and ξ' . The constraints are affine. The problem is to minimize ϵ and the errors ξ_i, ξ'_i so that the ℓ^1 -error is “squeezed down” to zero as much as possible, in the sense that the right-hand side of the inequality

$$\sum_{i=1}^m |y_i - x_i^\top w - b| \leq m\epsilon + \sum_{i=1}^m \xi_i + \sum_{i=1}^m \xi'_i$$

is as small as possible. As shown by Figure 56.2, the region associated with the constraint $w^\top x_i - z + b \leq \epsilon$ contains the ϵ -slab. Similarly, as illustrated by Figure 56.3, the region associated with the constraint $w^\top x_i - z + b \geq -\epsilon$, equivalently $-w^\top x_i + z - b \leq \epsilon$, also contains the ϵ -slab.

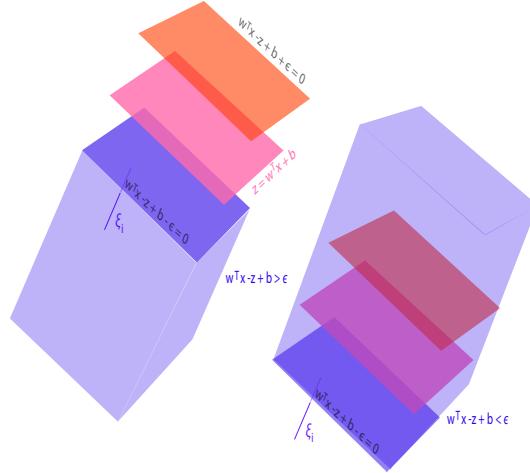

Figure 56.2: The two blue half spaces associated with the hyperplane $w^\top x_i - z + b = \epsilon$.

Observe that if we require $\epsilon = 0$, then the problem is equivalent to minimizing

$$\|y - Xw - b\mathbf{1}\|_1 + \frac{1}{2} w^\top w.$$

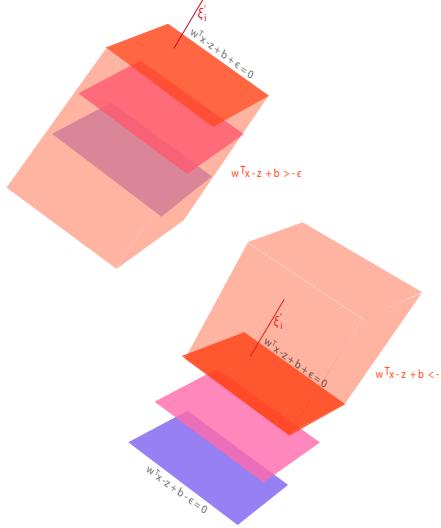

Figure 56.3: The two red half spaces associated with the hyperplane $w^\top x_i - z + b = -\epsilon$.

Thus it appears that the above problem is the version of Program (RR3) (see Section 55.2) in which the ℓ^2 -norm of $y - Xw - b\mathbf{1}$ is replaced by its ℓ^1 -norm. This a sort of “dual” of lasso (see Section 55.5) where $(1/2)w^\top w = (1/2)\|w\|_2^2$ is replaced by $\tau \|w\|_1$, and $\|y - Xw - b\mathbf{1}\|_1$ is replaced by $\|y - Xw - b\mathbf{1}\|_2^2$.

Proposition 56.1. *For any optimal solution, the equations*

$$\xi_i \xi'_i = 0, \quad i = 1, \dots, m \quad (\xi \xi')$$

hold. If $\epsilon > 0$, then the equations

$$\begin{aligned} w^\top x_i + b - y_i &= \epsilon + \xi_i \\ -w^\top x_i - b + y_i &= \epsilon + \xi'_i \end{aligned}$$

cannot hold simultaneously.

Proof. For an optimal solution we have

$$-\epsilon - \xi'_i \leq w^\top x_i + b - y_i \leq \epsilon + \xi_i.$$

If $w^\top x_i + b - y_i \geq 0$, then $\xi'_i = 0$ since the inequality

$$-\epsilon - \xi'_i \leq w^\top x_i + b - y_i$$

is trivially satisfied (because $\epsilon, \xi'_i \geq 0$), and if $w^\top x_i + b - y_i \leq 0$, then similarly $\xi_i = 0$. See Figure 56.4.

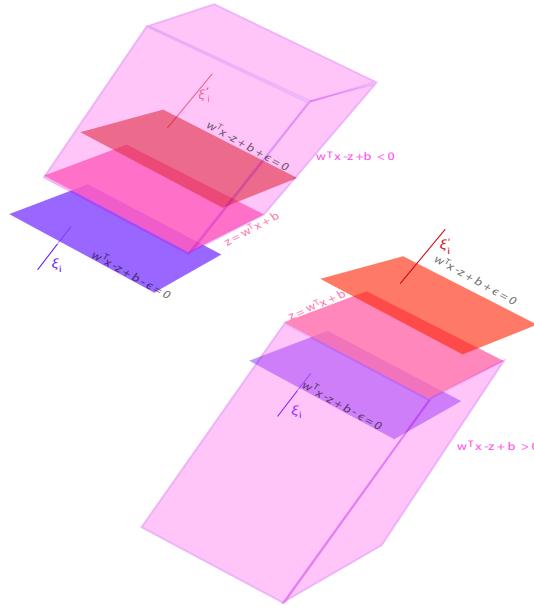

Figure 56.4: The two pink open half spaces associated with the hyperplane $w^\top x_i - z + b = 0$. Note, $\xi_i > 0$ is outside of the half space $w^\top x_i - z + b - \epsilon < 0$, and $\xi'_i > 0$ is outside of the half space $w^\top x_i - z + b + \epsilon > 0$.

Observe that the equations

$$\begin{aligned} w^\top x_i + b - y_i &= \epsilon + \xi_i \\ -w^\top x_i - b + y_i &= \epsilon + \xi'_i \end{aligned}$$

can only hold simultaneously if

$$\epsilon + \xi_i = -\epsilon - \xi'_i,$$

that is,

$$2\epsilon + \xi_i + \xi'_i = 0,$$

and since $\epsilon, \xi_i, \xi'_i \geq 0$, this can happen only if $\epsilon = \xi_i = \xi'_i = 0$, and then

$$w^\top x_i + b = y_i.$$

In particular, if $\epsilon > 0$, then the equations

$$\begin{aligned} w^\top x_i + b - y_i &= \epsilon + \xi_i \\ -w^\top x_i - b + y_i &= \epsilon + \xi'_i \end{aligned}$$

cannot hold simultaneously. □

Observe that if $\nu > 1$, then an optimal solution of the above program must yield $\epsilon = 0$. Indeed, if $\epsilon > 0$, we can reduce it by a small amount $\delta > 0$ and increase $\xi_i + \xi'_i$ by δ to still satisfy the constraints, but the objective function changes by the amount $-\nu\delta + \delta$, which is negative since $\nu > 1$, so $\epsilon > 0$ is not optimal.

Driving ϵ to zero is not the intended goal, because typically the data is not noise free so very few pairs (x_i, y_i) will satisfy the equation $w^\top x_i + b = y_i$, and then many pairs (x_i, y_i) will correspond to an error ($\xi_i > 0$ or $\xi'_i > 0$). Thus, *typically we assume that $0 < \nu \leq 1$* .

To construct the Lagrangian, we assign Lagrange multipliers $\lambda_i \geq 0$ to the constraints $w^\top x_i + b - y_i \leq \epsilon + \xi_i$, Lagrange multipliers $\mu_i \geq 0$ to the constraints $-w^\top x_i - b + y_i \leq \epsilon + \xi'_i$, Lagrange multipliers $\alpha_i \geq 0$ to the constraints $\xi_i \geq 0$, Lagrange multipliers $\beta_i \geq 0$ to the constraints $\xi'_i \geq 0$, and the Lagrange multiplier $\gamma \geq 0$ to the constraint $\epsilon \geq 0$. The Lagrangian is

$$\begin{aligned} L(w, b, \lambda, \mu, \gamma, \xi, \xi', \epsilon, \alpha, \beta) = & \frac{1}{2} w^\top w + C \left(\nu \epsilon + \frac{1}{m} \sum_{i=1}^m (\xi_i + \xi'_i) \right) - \gamma \epsilon - \sum_{i=1}^m (\alpha_i \xi_i + \beta_i \xi'_i) \\ & + \sum_{i=1}^m \lambda_i (w^\top x_i + b - y_i - \epsilon - \xi_i) + \sum_{i=1}^m \mu_i (-w^\top x_i - b + y_i - \epsilon - \xi'_i). \end{aligned}$$

The Lagrangian can also be written as

$$\begin{aligned} L(w, b, \lambda, \mu, \gamma, \xi, \xi', \epsilon, \alpha, \beta) = & \frac{1}{2} w^\top w + w^\top \left(\sum_{i=1}^m (\lambda_i - \mu_i) x_i \right) + \epsilon \left(C\nu - \gamma - \sum_{i=1}^m (\lambda_i + \mu_i) \right) \\ & + \sum_{i=1}^m \xi_i \left(\frac{C}{m} - \lambda_i - \alpha_i \right) + \sum_{i=1}^m \xi'_i \left(\frac{C}{m} - \mu_i - \beta_i \right) + b \left(\sum_{i=1}^m (\lambda_i - \mu_i) \right) - \sum_{i=1}^m (\lambda_i - \mu_i) y_i. \end{aligned}$$

To find the dual function $G(\lambda, \mu, \gamma, \alpha, \beta)$, we minimize $L(w, b, \lambda, \mu, \gamma, \xi, \xi', \epsilon, \alpha, \beta)$ with respect to the primal variables w, ϵ, b, ξ and ξ' . Observe that the Lagrangian is convex, and since $(w, \epsilon, \xi, \xi', b) \in \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^m \times \mathbb{R}^m \times \mathbb{R}$, a convex open set, by Theorem 40.13, the Lagrangian has a minimum iff $\nabla L_{w, \epsilon, b, \xi, \xi'} = 0$, so we compute the gradient $\nabla L_{w, \epsilon, b, \xi, \xi'}$. We obtain

$$\nabla L_{w, \epsilon, b, \xi, \xi'} = \begin{pmatrix} w + \sum_{i=1}^m (\lambda_i - \mu_i) x_i \\ C\nu - \gamma - \sum_{i=1}^m (\lambda_i + \mu_i) \\ \sum_{i=1}^m (\lambda_i - \mu_i) \\ \frac{C}{m} - \lambda - \alpha \\ \frac{C}{m} - \mu - \beta \end{pmatrix},$$

where

$$\left(\frac{C}{m} - \lambda - \alpha \right)_i = \frac{C}{m} - \lambda_i - \alpha_i, \quad \text{and} \quad \left(\frac{C}{m} - \mu - \beta \right)_i = \frac{C}{m} - \mu_i - \beta_i.$$

Consequently, if we set $\nabla L_{w,\epsilon,b,\xi,\xi'} = 0$, we obtain the equations

$$\begin{aligned} w &= \sum_{i=1}^m (\mu_i - \lambda_i) x_i = X^\top (\mu - \lambda), \\ C\nu - \gamma - \sum_{i=1}^m (\lambda_i + \mu_i) &= 0 \\ \sum_{i=1}^m (\lambda_i - \mu_i) &= 0 \\ \frac{C}{m} - \lambda - \alpha &= 0, \quad \frac{C}{m} - \mu - \beta = 0. \end{aligned} \tag{*}_w$$

Substituting the above equations in the second expression for the Lagrangian, we find that the dual function G is independent of the variables γ, α, β and is given by

$$G(\lambda, \mu) = -\frac{1}{2} \sum_{i,j=1}^m (\lambda_i - \mu_i)(\lambda_j - \mu_j) x_i^\top x_j - \sum_{i=1}^m (\lambda_i - \mu_i) y_i$$

if

$$\begin{aligned} \sum_{i=1}^m \lambda_i - \sum_{i=1}^m \mu_i &= 0 \\ \sum_{i=1}^m \lambda_i + \sum_{i=1}^m \mu_i + \gamma &= C\nu \\ \lambda + \alpha &= \frac{C}{m}, \quad \mu + \beta = \frac{C}{m}, \end{aligned}$$

and $-\infty$ otherwise.

The dual program is obtained by maximizing $G(\alpha, \mu)$ or equivalently by minimizing $-G(\alpha, \mu)$, over $\alpha, \mu \in \mathbb{R}_+^m$. Taking into account the fact that $\alpha, \beta \geq 0$ and $\gamma \geq 0$, we obtain the following dual program:

Dual Program for ν -SV Regression:

$$\text{minimize } \frac{1}{2} \sum_{i,j=1}^m (\lambda_i - \mu_i)(\lambda_j - \mu_j) x_i^\top x_j + \sum_{i=1}^m (\lambda_i - \mu_i) y_i$$

subject to

$$\begin{aligned} \sum_{i=1}^m \lambda_i - \sum_{i=1}^m \mu_i &= 0 \\ \sum_{i=1}^m \lambda_i + \sum_{i=1}^m \mu_i &\leq C\nu \\ 0 \leq \lambda_i &\leq \frac{C}{m}, \quad 0 \leq \mu_i \leq \frac{C}{m}, \quad i = 1, \dots, m, \end{aligned}$$

minimizing over α and μ .

Solving the dual program (for example, using ADMM, see Section 56.3) does not determine b , and for this we use the KKT conditions. The KKT conditions (for the primal program) are

$$\begin{aligned}\lambda_i(w^\top x_i + b - y_i - \epsilon - \xi_i) &= 0, \quad i = 1, \dots, m \\ \mu_i(-w^\top x_i - b + y_i - \epsilon - \xi'_i) &= 0, \quad i = 1, \dots, m \\ \gamma\epsilon &= 0 \\ \alpha_i\xi_i &= 0, \quad i = 1, \dots, m \\ \beta_i\xi'_i &= 0, \quad i = 1, \dots, m.\end{aligned}$$

If $\epsilon > 0$, since the equations

$$\begin{aligned}w^\top x_i + b - y_i &= \epsilon + \xi_i \\ -w^\top x_i - b + y_i &= \epsilon + \xi'_i\end{aligned}$$

cannot hold simultaneously, we must have

$$\lambda_i\mu_i = 0, \quad i = 1, \dots, m. \tag{\lambda\mu}$$

From the equations

$$\lambda_i + \alpha_i = \frac{C}{m}, \quad \mu_i + \beta_i = \frac{C}{m}, \quad \alpha_i\xi_i = 0, \quad \beta_i\xi'_i = 0,$$

we get the equations

$$\left(\frac{C}{m} - \lambda_i\right)\xi_i = 0, \quad \left(\frac{C}{m} - \mu_i\right)\xi'_i = 0, \quad i = 1, \dots, m. \tag{*}$$

Suppose we have optimal solution with $\epsilon > 0$. Using the above equations and the fact that $\lambda_i\mu_i = 0$ we obtain the following classification of the points x_i in terms of λ and μ .

- (1) $0 < \lambda_i < C/m$. By (*), $\xi_i = 0$, so the equation $w^\top x_i + b - y_i = \epsilon$ holds and x_i is on the blue margin hyperplane $H_{w,b-\epsilon}$. See Figure 56.5.
- (2) $0 < \mu_i < C/m$. By (*), $\xi'_i = 0$, so the equation $-w^\top x_i - b + y_i = \epsilon$ holds and x_i is on the red margin hyperplane $H_{w,b+\epsilon}$. See Figure 56.5.
- (3) $\lambda_i = C/m$. By $(\lambda\mu)$, $\mu_i = 0$, and by (*), $\xi'_i = 0$. Thus we have

$$\begin{aligned}w^\top x_i + b - y_i &= \epsilon + \xi_i \\ -w^\top x_i - b + y_i &\leq \epsilon.\end{aligned}$$

The second inequality is equivalent to $-\epsilon \leq w^\top x_i + b - y_i$, and since $\epsilon > 0$ and $\xi_i \geq 0$ it is trivially satisfied. If $\xi_i = 0$, then x_i is on the blue margin $H_{w,b-\epsilon}$, else x_i is an error and it lies in the open half-space bounded by the blue margin $H_{w,b-\epsilon}$ and not containing the best fit hyperplane $H_{w,b}$ (it is outside of the ϵ -slab). See Figure 56.5.

(4) $\mu_i = C/m$. By $(\lambda\mu)$, $\lambda_i = 0$, and by $(*)$, $\xi_i = 0$. Thus we have

$$\begin{aligned} w^\top x_i + b - y_i &\leq \epsilon \\ -w^\top x_i - b + y_i &= \epsilon + \xi'_i. \end{aligned}$$

The second equation is equivalent to $w^\top x_i + b - y_i = -\epsilon - \xi'_i$, and since $\epsilon > 0$ and $\xi'_i \geq 0$, the first inequality it is trivially satisfied. If $\xi'_i = 0$, then x_i is on the red margin $H_{w,b+\epsilon}$, else x_i is an error and it lies in the open half-space bounded by the red margin $H_{w,b-\epsilon}$ and not containing the best fit hyperplane $H_{w,b}$ (it is outside of the ϵ -slab). See Figure 56.5.

(5) $\lambda_i = 0$ and $\mu_i = 0$. By $(*)$, $\xi_i = 0$ and $\xi'_i = 0$, so we have

$$\begin{aligned} w^\top x_i + b - y_i &\leq \epsilon \\ -w^\top x_i - b + y_i &\leq \epsilon, \end{aligned}$$

that is

$$-\epsilon \leq w^\top x_i + b - y_i \leq \epsilon.$$

If $w^\top x_i + b - y_i = \epsilon$, then x_i is on the blue margin, and if $w^\top x_i + b - y_i = -\epsilon$, then x_i is on the red margin. If $-\epsilon < w^\top x_i + b - y_i < \epsilon$, then x_i is strictly inside of the ϵ -slab (bounded by the blue margin and the red margin). See Figure 56.6.

The above classification shows that the point x_i is an error iff $\lambda_i = C/m$ and $\xi_i > 0$ or or $\mu_i = C/m$ and $\xi'_i > 0$.

As in the case of SVM (see Section 50.6) we define support vectors as follows.

Definition 56.1. A vector x_i such that either $w^\top x_i + b - y_i = \epsilon$ (which implies $\xi_i = 0$) or $-w^\top x_i - b + y_i = \epsilon$ (which implies $\xi'_i = 0$) is called a *support vector*. Support vectors x_i such that $0 < \lambda_i < C/m$ and support vectors x_j such that $0 < \mu_j < C/m$ are *support vectors of type 1*. Support vectors of type 1 play a special role so we denote the sets of indices associated with them by

$$\begin{aligned} I_\lambda &= \{i \in \{1, \dots, m\} \mid 0 < \lambda_i < C/m\} \\ I_\mu &= \{j \in \{1, \dots, m\} \mid 0 < \mu_j < C/m\}. \end{aligned}$$

We denote their cardinalities by $numsvl_1 = |I_\lambda|$ and $numsvm_1 = |I_\mu|$. Support vectors x_i such that $\lambda_i = C/m$ and support vectors x_j such that $\mu_j = C/m$ are *support vectors of type 2*. Support vectors for which $\lambda_i = \mu_i = 0$ are called *exceptional support vectors*.

The following definition also gives a useful classification criterion.

Definition 56.2. A point x_i such that either $\lambda_i = C/m$ or $\mu_i = C/m$ is said to *fail the margin*. The sets of indices associated with the vectors failing the margin are denoted by

$$\begin{aligned} K_\lambda &= \{i \in \{1, \dots, m\} \mid \lambda_i = C/m\} \\ K_\mu &= \{j \in \{1, \dots, m\} \mid \mu_j = C/m\}. \end{aligned}$$

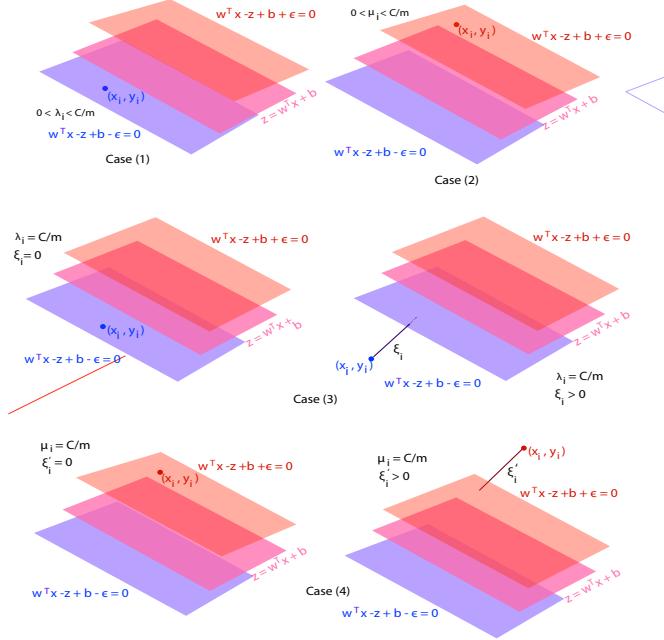

Figure 56.5: Classifying x_i in terms of nonzero λ and μ .

We denote their cardinalities by $p_f = |K_\lambda|$ and $q_f = |K_\mu|$.

Vectors u_i such that $\lambda_i > 0$ and vectors v_j such that $\mu_j > 0$ are said to have *margin at most ϵ* . A point x_i such that either $\lambda_i > 0$ or $\mu_i > 0$ is said to have *margin at most ϵ* . The sets of indices associated with these vectors are denoted by

$$\begin{aligned} I_{\lambda>0} &= \{i \in \{1, \dots, m\} \mid \lambda_i > 0\} \\ I_{\mu>0} &= \{j \in \{1, \dots, m\} \mid \mu_j > 0\}. \end{aligned}$$

We denote their cardinalities by $p_m = |I_{\lambda>0}|$ and $q_m = |I_{\mu>0}|$.

Points that fail the margin and are not on the boundary of the ϵ -slab lie outside the closed ϵ -slab, so they are errors, also called *outliers*; they correspond to $\xi_i > 0$ or $\xi'_i > 0$.

Observe that we have the equations $I_\lambda \cup K_\lambda = I_{\lambda>0}$ and $I_\mu \cup K_\mu = I_{\mu>0}$, and the inequalities $p_f \leq p_m$ and $q_f \leq q_m$.

We also have the following results showing that p_f, q_f, p_m and q_m have a direct influence on the choice of ν .

Proposition 56.2. (1) Let p_f be the number of points x_i such that $\lambda_i = C/m$, and let q_f be the number of points x_i such that $\mu_i = C/m$. We have $p_f, q_f \leq (m\nu)/2$.

(2) Let p_m be the number of points x_i such that $\lambda_i > 0$, and let q_m be the number of points x_i such that $\mu_i > 0$. We have $p_m, q_m \geq (m\nu)/2$.

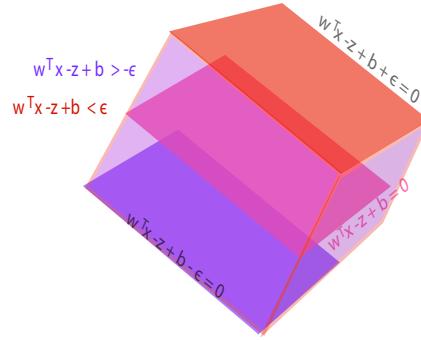

Figure 56.6: The closed ϵ - tube associated with zero multiplier classification, namely $\lambda_i = 0$ and $\mu_i = 0$.

(3) If $p_f \geq 1$ or $q_f \geq 1$, then $\nu \geq 2/m$.

Proof. (1) Recall that for an optimal solution with $w \neq 0$ and $\epsilon > 0$ we have $\gamma = 0$, so we have the equations

$$\sum_{i=1}^m \lambda_i = \frac{C\nu}{2} \quad \text{and} \quad \sum_{j=1}^m \mu_j = \frac{C\nu}{2}.$$

If there are p_f points such that $\lambda_i = C/m$, then

$$\frac{C\nu}{2} = \sum_{i=1}^m \lambda_i \geq p_f \frac{C}{m},$$

so

$$p_f \leq \frac{m\nu}{2}.$$

A similar reasoning applies if there are q_f points such that $\mu_i = C/m$, and we get

$$q_f \leq \frac{m\nu}{2}.$$

(2) If $I_{\lambda>0} = \{i \in \{1, \dots, m\} \mid \lambda_i > 0\}$ and $p_m = |I_{\lambda>0}|$, then

$$\frac{C\nu}{2} = \sum_{i=1}^m \lambda_i = \sum_{i \in I_{\lambda>0}} \lambda_i,$$

and since $\lambda_i \leq C/m$, we have

$$\frac{C\nu}{2} = \sum_{i \in I_{\lambda>0}} \lambda_i \leq p_m \frac{C}{m},$$

which yields

$$p_m \geq \frac{\nu m}{2}.$$

A similar reasoning applies if $\mu_i > 0$.

(3) This follows immediately from (1). \square

Proposition 56.2 yields bounds on ν , namely

$$\max \left\{ \frac{2p_f}{m}, \frac{2q_f}{m} \right\} \leq \nu \leq \min \left\{ \frac{2p_m}{m}, \frac{2q_m}{m} \right\},$$

with $p_f \leq p_m$, $q_f \leq q_m$, $p_f + q_f \leq m$ and $p_m + q_m \leq m$. Also, $p_f = q_f = 0$ means that the ϵ -slab is wide enough so that there are no errors (no points strictly outside the slab).

Observe that a small value of ν keeps p_f and q_f small, which is achieved if the ϵ -slab is wide. A large value of ν allows p_m and q_m to be fairly large, which is achieved if the ϵ -slab is narrow. **Thus the smaller ν is, the wider the ϵ -slab is, and the larger ν is, the narrower the ϵ -slab is.**

56.2 Existence of Support Vectors

We now consider the issue of the existence of support vectors. We will show that in the generic case, for any optimal solution for which $\epsilon > 0$, there is some support vector on the blue margin *and* some support vector on the red margin. Here generic means that there is an optimal solution for some $\nu < (m - 1)/m$.

If the data set (X, y) is well fit by some affine function $f(x) = w^\top x + b$, in the sense that for many pairs (x_i, y_i) we have $y_i = w^\top x_i + b$ and the ℓ^1 -error

$$\sum_{i=1}^m |w^\top x_i + b - y_i|$$

is small, then an optimal solution may have $\epsilon = 0$. Geometrically, many points (x_i, y_i) belong to the hyperplane $H_{w,b}$. The situation in which $\epsilon = 0$ corresponds to minimizing the ℓ^1 -error with a quadratic penalization of w . This is a sort of dual of lasso. The fact that the affine function $f(x) = w^\top x + b$ fits perfectly many points corresponds to the fact that an ℓ^1 -minimization tends to encourage sparsity. In this case, if C is chosen too small, it is possible that all points are errors (although “small”) and there are no support vectors. But if C is large enough, the solution will be sparse and there will be *many* support vectors on the hyperplane $H_{w,b}$.

Let $E_\lambda = \{i \in \{1, \dots, m\} \mid \xi_i > 0\}$, $E_\mu = \{j \in \{1, \dots, m\} \mid \xi'_j > 0\}$, $p_{sf} = |E_\lambda|$ and $q_{sf} = |E_\mu|$. Obviously, E_λ and E_μ are disjoint.

Given any real numbers u, v, x, y , if $\max\{u, v\} < \min\{x, y\}$, then $u < x$ and $v < y$. This is because $u, v \leq \max\{u, v\} < \min\{x, y\} \leq x, y$.

Proposition 56.3. *If $\nu < (m - 1)/m$, then $p_f < \lfloor m/2 \rfloor$ and $q_f < \lfloor m/2 \rfloor$.*

Proof. By Proposition 56.2, $\max\{2p_f/m, 2q_f/m\} \leq \nu$. If m is even, say $m = 2k$, then

$$2p_f/m = 2p_f/(2k) \leq \nu < (m - 1)/m = (2k - 1)/2k,$$

so $2p_f < 2k - 1$, which implies $p_f < k = \lfloor m/2 \rfloor$. A similar argument shows that $q_f < k = \lfloor m/2 \rfloor$.

If m is odd, say $m = 2k + 1$, then

$$2p_f/m = 2p_f/(2k + 1) \leq \nu < (m - 1)/m = 2k/(2k + 1),$$

so $2p_f < 2k$, which implies $p_f < k = \lfloor m/2 \rfloor$. A similar argument shows that $q_f < k = \lfloor m/2 \rfloor$. \square

Since $p_{sf} \leq p_f$ and $q_{sf} \leq q_f$, we also have $p_{sf} < \lfloor m/2 \rfloor$ and $q_{sf} < \lfloor m/2 \rfloor$. This implies that $\{1, \dots, m\} - (E_\lambda \cup E_\mu)$ contains at least two elements and there are constraints corresponding to at least two $i \notin (E_\lambda \cup E_\mu)$ (in which case $\xi_i = \xi'_i = 0$), of the form

$$\begin{array}{ll} w^\top x_i + b - y_i \leq \epsilon & i \notin (E_\lambda \cup E_\mu) \\ -w^\top x_i - b + y_i \leq \epsilon & i \notin (E_\lambda \cup E_\mu). \end{array}$$

If $w^\top x_i + b - y_i = \epsilon$ for some $i \notin (E_\lambda \cup E_\mu)$ and $-w^\top x_j - b + y_j = \epsilon$ for some $j \notin (E_\lambda \cup E_\mu)$ with $i \neq j$, then we have a blue support vector and a red support vector. Otherwise, we show how to modify b and ϵ to obtain an optimal solution with a blue support vector and a red support vector.

Proposition 56.4. *For every optimal solution $(w, b, \epsilon, \xi, \xi')$ with $w \neq 0$ and $\epsilon > 0$, if*

$$\nu < (m - 1)/m$$

and if either no x_i is a blue support vector or no x_i is a red support vector, then there is another optimal solution (for the same w) with some i_0 such that $\xi_{i_0} = 0$ and $w^\top x_{i_0} + b - y_{i_0} = \epsilon$, and there is some j_0 such that $\xi'_{j_0} = 0$ and $-w^\top x_{j_0} - b + y_{j_0} = \epsilon$; in other words, some x_{i_0} is a blue support vector and some x_{j_0} is a red support vector (with $i_0 \neq j_0$). If all points (x_i, y_i) that are not errors lie on one of the margin hyperplanes, then there is an optimal solution for which $\epsilon = 0$.

Proof. By Proposition 56.3 if $\nu < (m - 1)/m$, then $p_f < \lfloor m/2 \rfloor$ and $q_f < \lfloor m/2 \rfloor$, so the following constraints hold:

$$\begin{array}{lll} w^\top x_i + b - y_i = \epsilon + \xi_i & \xi_i > 0 & i \in E_\lambda \\ -w^\top x_j - b + y_j = \epsilon + \xi'_j & \xi'_j > 0 & j \in E_\mu \\ w^\top x_i + b - y_i \leq \epsilon & & i \notin (E_\lambda \cup E_\mu) \\ -w^\top x_i - b + y_i \leq \epsilon & & i \notin (E_\lambda \cup E_\mu), \end{array}$$

where $|\{1, \dots, m\} - (E_\lambda \cup E_\mu)| \geq 2$.

If our optimal solution does not have a blue support vector and a red support vector, then either $w^\top x_i + b - y_i < \epsilon$ for all $i \notin (E_\lambda \cup E_\mu)$ or $-w^\top x_i - b + y_i < \epsilon$ for all $i \notin (E_\lambda \cup E_\mu)$.

Case 1. We have

$$\begin{aligned} w^\top x_i + b - y_i &< \epsilon & i \notin (E_\lambda \cup E_\mu) \\ -w^\top x_i - b + y_i &\leq \epsilon & i \notin (E_\lambda \cup E_\mu). \end{aligned}$$

There are two subcases.

Case 1a. Assume that there is some $j \notin (E_\lambda \cup E_\mu)$ such that $-w^\top x_j - b + y_j = \epsilon$. Our strategy is to decrease ϵ and increase b by a small amount θ in such a way that some inequality $w^\top x_i + b - y_i < \epsilon$ becomes an equation for some $i \notin (E_\lambda \cup E_\mu)$. Geometrically, this amounts to raising the separating hyperplane $H_{w,b}$ and decreasing the width of the slab, keeping the red margin hyperplane unchanged. See Figure 56.7.

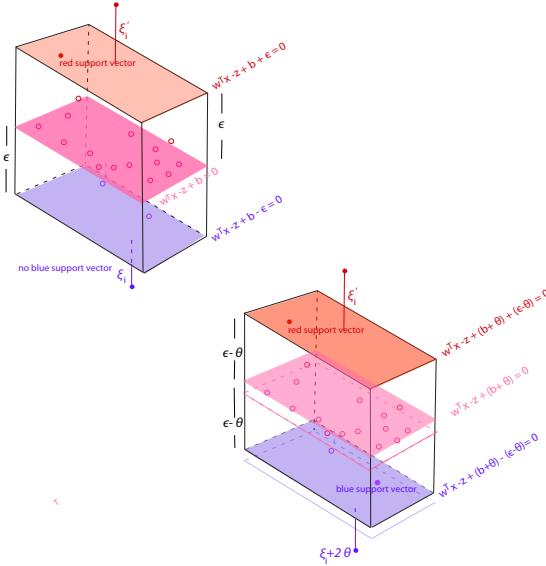

Figure 56.7: In this illustration points within the ϵ -tube are denoted by open circles. In the original, upper left configuration, there is no blue support vector. By raising the pink separating hyperplane and decreasing the width of the slab, we end up with a blue support vector.

The inequalities imply that

$$-\epsilon \leq w^\top x_i + b - y_i < \epsilon.$$

Let us pick θ such that

$$\theta = (1/2) \min\{\epsilon - w^\top x_i - b + y_i \mid i \notin (E_\lambda \cup E_\mu)\}.$$

Our hypotheses imply that $\theta > 0$, and we have $\theta \leq \epsilon$, because $(1/2)(\epsilon - w^\top x_i - b + y_i) \leq \epsilon$ is equivalent to $\epsilon - w^\top x_i - b + y_i \leq 2\epsilon$ which is equivalent to $-w^\top x_i - b + y_i \leq \epsilon$, which holds for all $i \notin (E_\lambda \cup E_\mu)$ by hypothesis.

We can write

$$\begin{aligned} w^\top x_i + b + \theta - y_i &= \epsilon - \theta + \xi_i + 2\theta & \xi_i > 0 & i \in E_\lambda \\ -w^\top x_j - (b + \theta) + y_j &= \epsilon - \theta + \xi'_j & \xi'_j > 0 & j \in E_\mu \\ w^\top x_i + b + \theta - y_i &\leq \epsilon - \theta & & i \notin (E_\lambda \cup E_\mu) \\ -w^\top x_i - (b + \theta) + y_i &\leq \epsilon - \theta & & i \notin (E_\lambda \cup E_\mu). \end{aligned}$$

By hypothesis

$$-w^\top x_j - (b + \theta) + y_j = \epsilon - \theta \quad \text{for some } j \notin (E_\lambda \cup E_\mu)$$

and by the choice of θ ,

$$w^\top x_i + b + \theta - y_i = \epsilon - \theta \quad \text{for some } i \notin (E_\lambda \cup E_\mu).$$

The value of $C > 0$ is irrelevant in the following argument so we may assume that $C = 1$. The new value of the objective function is

$$\begin{aligned} \omega(\theta) &= \frac{1}{2}w^\top w + \nu(\epsilon - \theta) + \frac{1}{m} \left(\sum_{i \in E_\lambda} (\xi_i + 2\theta) + \sum_{j \in E_\mu} \xi'_j \right) \\ &= \frac{1}{2}w^\top w + \nu\epsilon + \frac{1}{m} \left(\sum_{i \in E_\lambda} \xi_i + \sum_{j \in E_\mu} \xi'_j \right) - \left(\nu - \frac{2p_{sf}}{m} \right) \theta. \end{aligned}$$

By Proposition 56.2 we have

$$\max \left\{ \frac{2p_f}{m}, \frac{2q_f}{m} \right\} \leq \nu$$

and $p_{sf} \leq p_f$ and $q_{sf} \leq q_f$, which implies that

$$\nu - \frac{2p_{sf}}{m} \geq 0, \tag{*_1}$$

and so $\omega(\theta) \leq \omega(0)$. If inequality $(*_1)$ is strict, then this contradicts the optimality of the original solution. Therefore, $\nu = 2p_{sf}/m$, $\omega(\theta) = \omega(0)$ and $(w, b + \theta, \epsilon - \theta, \xi + 2\theta, \xi')$ is an optimal solution such that

$$\begin{aligned} w^\top x_i + b + \theta - y_i &= \epsilon - \theta \\ -w^\top x_j - (b + \theta) + y_j &= \epsilon - \theta \end{aligned}$$

for some $i, j \notin (E_\lambda \cup E_\mu)$ with $i \neq j$.

Observe that the exceptional case in which $\theta = \epsilon$ may arise. In this case all points (x_i, y_i) that are not errors (strictly outside the ϵ -slab) are on the red margin hyperplane. This case can only arise if $\nu = 2p_{sf}/m$.

Case 1b. We have $-w^\top x_i - b + y_i < \epsilon$ for all $i \notin (E_\lambda \cup E_\mu)$. Our strategy is to decrease ϵ and increase the errors by a small θ in such a way that some inequality becomes an equation for some $i \notin (E_\lambda \cup E_\mu)$. Geometrically, this corresponds to decreasing the width of the slab, keeping the separating hyperplane unchanged. See Figures 56.8 and 56.9. Then we are reduced to *Case 1a* or *Case 2a*.

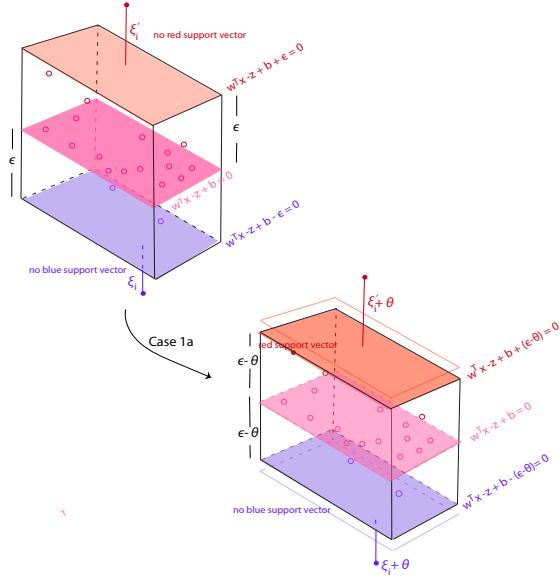

Figure 56.8: In this illustration points within the ϵ -tube are denoted by open circles. In the original, upper left configuration, there is no blue support vector and no red support vector. By decreasing the width of the slab, we end up with a red support vector and reduce to Case 1a.

We have

$$\begin{aligned}
 w^\top x_i + b - y_i &= \epsilon + \xi_i & \xi_i > 0 & i \in E_\lambda \\
 -w^\top x_j - b + y_j &= \epsilon + \xi'_j & \xi'_j > 0 & j \in E_\mu \\
 w^\top x_i + b - y_i &< \epsilon & & i \notin (E_\lambda \cup E_\mu) \\
 -w^\top x_i - b + y_i &< \epsilon & & i \notin (E_\lambda \cup E_\mu).
 \end{aligned}$$

Let us pick θ such that

$$\theta = \min\{\epsilon - (w^\top x_i + b - y_i), \epsilon + w^\top x_i + b - y_i \mid i \notin (E_\lambda \cup E_\mu)\},$$

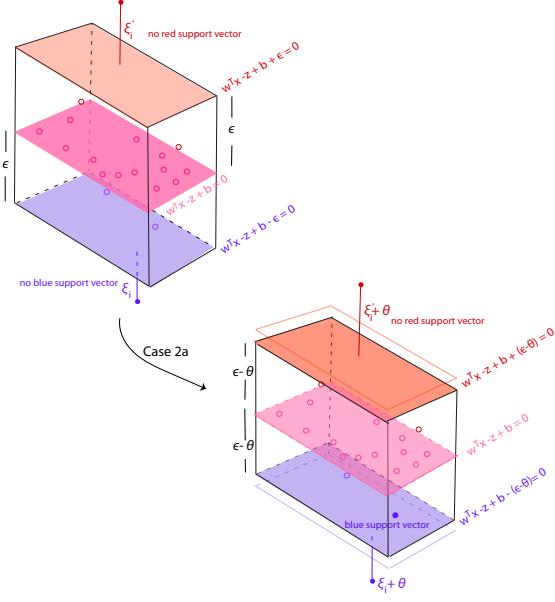

Figure 56.9: In this illustration points within ϵ -tube are denoted by open circles. In the original, upper left configuration, there is no blue support vector and no red support vector. By decreasing the width of the slab, we end up with a blue support vector and reduce to Case 2a.

Our hypotheses imply that $0 < \theta < \epsilon$. We can write

$$\begin{aligned}
 w^\top x_i + b - y_i &= \epsilon - \theta + \xi_i + \theta & \xi_i > 0 & i \in E_\lambda \\
 -w^\top x_j - b + y_j &= \epsilon - \theta + \xi'_j + \theta & \xi'_j > 0 & j \in E_\mu \\
 w^\top x_i + b - y_i &\leq \epsilon - \theta & i \notin (E_\lambda \cup E_\mu) \\
 -w^\top x_i - b + y_i &\leq \epsilon - \theta & i \notin (E_\lambda \cup E_\mu),
 \end{aligned}$$

and by the choice of θ , either

$$w^\top x_i + b - y_i = \epsilon - \theta \quad \text{for some } i \notin (E_\lambda \cup E_\mu)$$

or

$$-w^\top x_i - b + y_i = \epsilon - \theta \quad \text{for some } i \notin (E_\lambda \cup E_\mu).$$

The new value of the objective function is

$$\begin{aligned}
 \omega(\theta) &= \frac{1}{2} w^\top w + \nu(\epsilon - \theta) + \frac{1}{m} \left(\sum_{i \in E_\lambda} (\xi_i + \theta) + \sum_{j \in E_\mu} (\xi'_j + \theta) \right) \\
 &= \frac{1}{2} w^\top w + \nu\epsilon + \frac{1}{m} \left(\sum_{i \in E_\lambda} \xi_i + \sum_{j \in E_\mu} \xi'_j \right) - \left(\nu - \frac{p_{sf} + q_{sf}}{m} \right) \theta.
 \end{aligned}$$

Since $\max\{2p_f/m, 2q_f/m\} \leq \nu$ implies that $(p_f + q_f)/m \leq \nu$ and $p_{sf} \leq p_f, q_{sf} \leq q_f$, we have

$$\nu - \frac{p_{sf} + q_{sf}}{m} \geq 0, \quad (*_2)$$

and so $\omega(\theta) \leq \omega(0)$. If inequality $(*_2)$ is strict, then this contradicts the optimality of the original solution. Therefore, $\nu = (p_{sf} + q_{sf})/m$, $\omega(\theta) = \omega(0)$ and $(w, b, \epsilon - \theta, \xi + \theta, \xi' + \theta)$ is an optimal solution such that either

$$w^\top x_i + b - y_i = \epsilon - \theta \quad \text{for some } i \notin (E_\lambda \cup E_\mu)$$

or

$$-w^\top x_i - b + y_i = \epsilon - \theta \quad \text{for some } i \notin (E_\lambda \cup E_\mu).$$

We are now reduced to *Case 1a* or *Case 2a*.

Case 2. We have

$$\begin{aligned} w^\top x_i + b - y_i &\leq \epsilon & i \notin (E_\lambda \cup E_\mu) \\ -w^\top x_i - b + y_i &< \epsilon & i \notin (E_\lambda \cup E_\mu). \end{aligned}$$

Again there are two subcases.

Case 2a. Assume that there is some $i \notin (E_\lambda \cup E_\mu)$ such that $w^\top x_i + b - y_i = \epsilon$. Our strategy is to decrease ϵ and decrease b by a small amount θ in such a way that some inequality $-w^\top x_j - b + y_j < \epsilon$ becomes an equation for some $j \notin (E_\lambda \cup E_\mu)$. Geometrically, this amounts to lowering the separating hyperplane $H_{w,b}$ and decreasing the width of the slab, keeping the blue margin hyperplane unchanged. See Figure 56.10.

The inequalities imply that

$$-\epsilon < w^\top x_i + b - y_i \leq \epsilon.$$

Let us pick θ such that

$$\theta = (1/2) \min\{\epsilon - (-w^\top x_i - b + y_i) \mid i \notin (E_\lambda \cup E_\mu)\}.$$

Our hypotheses imply that $\theta > 0$, and we have $\theta \leq \epsilon$, because $(1/2)(\epsilon - (-w^\top x_i - b + y_i)) \leq \epsilon$ is equivalent to $\epsilon - (-w^\top x_i - b + y_i) \leq 2\epsilon$ which is equivalent to $w^\top x_i + b - y_i \leq \epsilon$ which holds for all $i \notin (E_\lambda \cup E_\mu)$ by hypothesis.

We can write

$$\begin{aligned} w^\top x_i + b - \theta - y_i &= \epsilon - \theta + \xi_i & \xi_i > 0 & i \in E_\lambda \\ -w^\top x_j - (b - \theta) + y_j &= \epsilon - \theta + \xi'_j + 2\theta & \xi'_j > 0 & j \in E_\mu \\ w^\top x_i + b - \theta - y_i &\leq \epsilon - \theta & & i \notin (E_\lambda \cup E_\mu) \\ -w^\top x_i - (b - \theta) + y_i &\leq \epsilon - \theta & & i \notin (E_\lambda \cup E_\mu). \end{aligned}$$

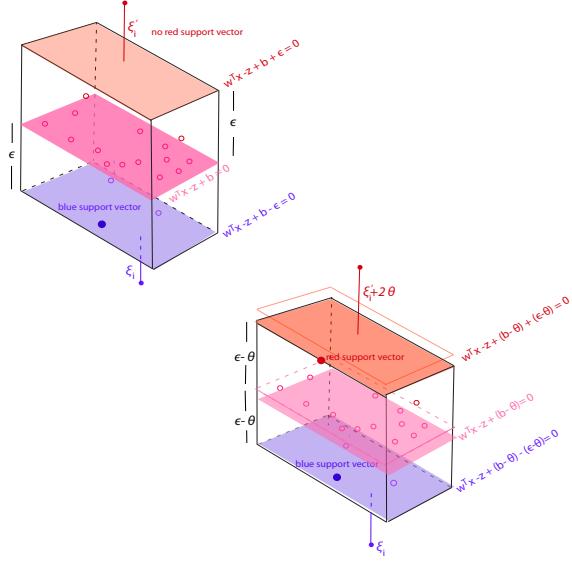

Figure 56.10: In this illustration points within the ϵ -tube are denoted by open circles. In the original, upper left configuration, there is no red support vector. By lowering the pink separating hyperplane and decreasing the width of the slab, we end up with a red support vector.

By hypothesis

$$w^\top x_i + (b - \theta) - y_i = \epsilon - \theta \quad \text{for some } i \notin (E_\lambda \cup E_\mu),$$

and by the choice of θ ,

$$-w^\top x_j - (b - \theta) + y_j = \epsilon - \theta \quad \text{for some } j \notin (E_\lambda \cup E_\mu).$$

The new value of the objective function is

$$\begin{aligned} \omega(\theta) &= \frac{1}{2} w^\top w + \nu(\epsilon - \theta) + \frac{1}{m} \left(\sum_{i \in E_\lambda} \xi_i + \sum_{j \in E_\mu} (\xi'_j + 2\theta) \right) \\ &= \frac{1}{2} w^\top w + \nu\epsilon + \frac{1}{m} \left(\sum_{i \in E_\lambda} \xi_i + \sum_{j \in E_\mu} \xi'_j \right) - \left(\nu - \frac{2q_{sf}}{m} \right) \theta. \end{aligned}$$

The rest of the proof is similar except that $2p_{sf}/m$ is replaced by $2q_{sf}/m$. Observe that the exceptional case in which $\theta = \epsilon$ may arise. In this case all points (x_i, y_i) that are not errors (strictly outside the ϵ -slab) are on the blue margin hyperplane. This case can only arise if $\nu = 2q_{sf}/m$.

Case 2b. We have $w^\top x_i + b - y_i < \epsilon$ for all $i \notin (E_\lambda \cup E_\mu)$. Since we also assumed that $-w^\top x_i - b + y_i < \epsilon$ for all $i \notin (E_\lambda \cup E_\mu)$, Case 2b is identical to Case 1b and we are done. \square

The proof of Proposition 56.4 reveals that there are three critical values for ν :

$$\frac{2p_{sf}}{m}, \quad \frac{2q_{sf}}{m}, \quad \frac{p_{sf} + q_{sf}}{m}.$$

These values can be avoided by requiring the strict inequality

$$\max \left\{ \frac{2p_{sf}}{m}, \frac{2q_{sf}}{m} \right\} < \nu.$$

Then the following corollary holds.

Theorem 56.5. *For every optimal solution $(w, b, \epsilon, \xi, \xi')$ with $w \neq 0$ and $\epsilon > 0$, if*

$$\max \left\{ \frac{2p_{sf}}{m}, \frac{2q_{sf}}{m} \right\} < \nu < (m - 1)/m,$$

then some x_{i_0} is a blue support vector and some x_{j_0} is a red support vector (with $i_0 \neq j_0$).

Proof. We proceed by contradiction. Suppose that for every optimal solution with $w \neq 0$ and $\epsilon > 0$ no x_i is a blue support vector or no x_i is a red support vector. Since $\nu < (m - 1)/m$, Proposition 56.4 holds, so there is another optimal solution. But since the critical values of ν are avoided, the proof of Proposition 56.4 shows that the value of the objective function for this new optimal solution is strictly smaller than the original optimal value, a contradiction. \square

Remark: If an optimal solution has $\epsilon = 0$, then depending on the value of C there may not be any support vectors, or many.

If the primal has an optimal solution with $w \neq 0$ and $\epsilon > 0$, then by $(*_w)$ and since

$$\sum_{i=1}^m \lambda_i - \sum_{i=1}^m \mu_i = 0 \quad \text{and} \quad \lambda_i \mu_i = 0,$$

there is i_0 such that $\lambda_{i_0} > 0$ and some $j_0 \neq i_0$ such that $\mu_{j_0} > 0$.

Under the mild hypothesis called the **Standard Margin Hypothesis** that there is some i_0 such that $0 < \alpha_{i_0} < \frac{C}{m}$ and there is some $j_0 \neq i_0$ such that $0 < \mu_{j_0} < \frac{C}{m}$, in other words there is a blue support vector of type 1 and there is a red support vector of type 1, then by $(*)$ we have $\xi_{i_0} = 0, \xi'_{j_0} = 0$, and we have the two equations

$$\begin{aligned} w^\top x_{i_0} + b - y_{i_0} &= \epsilon \\ -w^\top x_{j_0} - b + y_{j_0} &= \epsilon, \end{aligned}$$

so b and ϵ can be computed. In particular,

$$\begin{aligned} b &= \frac{1}{2} (y_{i_0} + y_{j_0} - w^\top (x_{i_0} + x_{j_0})) \\ \epsilon &= \frac{1}{2} (y_{j_0} - y_{i_0} + w^\top (x_{i_0} - x_{j_0})). \end{aligned}$$

The function $f(x) = w^\top x + b$ (often called *regression estimate*) is given by

$$f(x) = \sum_{i=1}^m (\mu_i - \lambda_i) x_i^\top x + b.$$

In practice, due to numerical inaccuracy, it is complicated to write a computer program that will select two *distinct indices* as above. It is preferable to compute the list I_λ of indices i such that $0 < \lambda_i < C/m$ and the list I_μ of indices j such that $0 < \mu_j < C/m$. Then it is easy to see that

$$\begin{aligned} b &= \left(\left(\sum_{i_0 \in I_\lambda} y_{i_0} \right) / |I_\lambda| + \left(\sum_{j_0 \in I_\mu} y_{j_0} \right) / |I_\mu| - w^\top \left(\left(\sum_{i_0 \in I_\lambda} x_{i_0} \right) / |I_\lambda| + \left(\sum_{j_0 \in I_\mu} x_{j_0} \right) / |I_\mu| \right) \right) / 2 \\ \epsilon &= \left(\left(\sum_{j_0 \in I_\mu} y_{j_0} \right) / |I_\mu| - \left(\sum_{i_0 \in I_\lambda} y_{i_0} \right) / |I_\lambda| + w^\top \left(\left(\sum_{i_0 \in I_\lambda} x_{i_0} \right) / |I_\lambda| - \left(\sum_{j_0 \in I_\mu} x_{j_0} \right) / |I_\mu| \right) \right) / 2. \end{aligned}$$

These formulae are numerically a lot more stable, but we still have to be cautious to set suitable tolerance factors to decide whether $\lambda_i > 0$ and $\lambda_i < C/m$ (and similarly for μ_i).

The following result gives sufficient conditions for expressing ϵ in terms of a single support vector.

Proposition 56.6. *For every optimal solution $(w, b, \epsilon, \xi, \xi')$ with $w \neq 0$ and $\epsilon > 0$, if*

$$\max \left\{ \frac{2p_{sf}}{m}, \frac{2q_{sf}}{m} \right\} < \nu < (m-1)/m,$$

then ϵ and b are determined from a solution (λ, μ) of the dual in terms of a single support vector.

Proof sketch. If we express that the duality gap is zero we obtain the following equation expressing ϵ in terms of b :

$$\begin{aligned} C \left(\nu - \frac{p_f + q_f}{m} \right) \epsilon &= - (\lambda^\top \quad \mu^\top) P \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - (y^\top \quad -y^\top) \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ &\quad - \frac{C}{m} \left(w^\top \left(\sum_{i \in K_\lambda} x_i - \sum_{j \in K_\mu} x_j \right) - \sum_{i \in K_\lambda} y_i + \sum_{j \in K_\mu} y_j + (p_f - q_f)b \right). \end{aligned}$$

The proof is very similar to the proof of the corresponding formula in Section 56.5. By Theorem 56.5, there is some support vector x_i , say

$$w^\top x_{i_0} + b - y_{i_0} = \epsilon \quad \text{or} \quad -w^\top x_{j_0} - b + y_{j_0} = \epsilon.$$

Then we find an equation expressing ϵ in terms of λ, μ and w , provided that $\nu \neq 2p_f/m$ and $\nu \neq 2q_f/m$. The proof is analogous to the proof of Proposition 54.4 and is left as an exercise. \square

56.3 Solving ν -Regression Using ADMM

The quadratic functional $F(\lambda, \mu)$ occurring in the dual program given by

$$F(\lambda, \mu) = \frac{1}{2} \sum_{i,j=1}^m (\lambda_i - \mu_i)(\lambda_j - \mu_j) x_i^\top x_j + \sum_{i=1}^m (\lambda_i - \mu_i) y_i$$

is not of the form $\frac{1}{2} (\lambda^\top - \mu^\top) P \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + q^\top \begin{pmatrix} \lambda \\ \mu \end{pmatrix}$, but it can be converted in such a form using a trick. First, if we let \mathbf{K} be the $m \times m$ symmetric matrix $\mathbf{K} = XX^\top = (x_i^\top x_j)$, then we have

$$F(\lambda, \mu) = \frac{1}{2} (\lambda^\top - \mu^\top) \mathbf{K} (\lambda - \mu) + y^\top \lambda - y^\top \mu.$$

Consequently, if we define the $2m \times 2m$ symmetric matrix P by

$$P = \begin{pmatrix} XX^\top & -XX^\top \\ -XX^\top & XX^\top \end{pmatrix} = \begin{pmatrix} \mathbf{K} & -\mathbf{K} \\ -\mathbf{K} & \mathbf{K} \end{pmatrix}$$

and the $2m \times 1$ matrix q by

$$q = \begin{pmatrix} y \\ -y \end{pmatrix},$$

it is easy to check that

$$F(\lambda, \mu) = \frac{1}{2} (\lambda^\top - \mu^\top) P \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + q^\top \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = \frac{1}{2} \lambda^\top \mathbf{K} \lambda + \frac{1}{2} \mu^\top \mathbf{K} \mu - \lambda^\top \mathbf{K} \mu + y^\top \lambda - y^\top \mu. \quad (*_q)$$

Since

$$\frac{1}{2} (\lambda^\top - \mu^\top) P \begin{pmatrix} \lambda \\ \mu \end{pmatrix} = \frac{1}{2} (\lambda^\top - \mu^\top) \mathbf{K} (\lambda - \mu)$$

and the matrix $\mathbf{K} = XX^\top$ is symmetric positive semidefinite, the matrix P is also symmetric

positive semidefinite. Thus we are in a position to apply ADMM since the constraints are

$$\begin{aligned}\sum_{i=1}^m \lambda_i - \sum_{i=1}^m \mu_i &= 0 \\ \sum_{i=1}^m \lambda_i + \sum_{i=1}^m \mu_i + \gamma &= C\nu \\ \lambda + \alpha &= \frac{C}{m}, \quad \mu + \beta = \frac{C}{m},\end{aligned}$$

namely affine. We need to check that the $(2m+2) \times (4m+1)$ matrix A corresponding to this system has rank $2m+2$. Let us clarify this point. The matrix A corresponding to the above equations is

$$A = \begin{pmatrix} \mathbf{1}_m^\top & -\mathbf{1}_m^\top & 0_m^\top & 0_m^\top & 0 \\ \mathbf{1}_m^\top & \mathbf{1}_m^\top & 0_m^\top & 0_m^\top & 1 \\ I_m & 0_{m,m} & I_m & 0_{m,m} & 0_m \\ 0_{m,m} & I_m & 0_{m,m} & I_m & 0_m \end{pmatrix}.$$

For example, for $m = 3$ we have the 8×13 matrix

$$\begin{pmatrix} 1 & 1 & 1 & -1 & -1 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \end{pmatrix}.$$

We leave it as an exercise to show that A has rank $2m+2$. Recall that

$$q = \begin{pmatrix} y \\ -y \end{pmatrix}$$

and we also define the vector c (of dimension $2m+2$) as

$$c = \begin{pmatrix} 0 \\ C\nu \\ \frac{C}{m} \mathbf{1}_{2m} \end{pmatrix}.$$

The constraints are given by the system of affine equations $Ax = c$, where

$$x = (\lambda^\top \ \mu^\top \ \alpha^\top \ \beta^\top \ \gamma)^\top.$$

Since there are $4m + 1$ Lagrange multipliers $(\lambda, \mu, \alpha, \beta, \gamma)$, we need to pad the $2m \times 2m$ matrix P with zeros to make it into a $(4m + 1) \times (4m + 1)$ matrix

$$P_a = \begin{pmatrix} P & 0_{2m, 2m+1} \\ 0_{2m+1, 2m} & 0_{2m+1, 2m+1} \end{pmatrix}.$$

Similarly, we pad q with zeros to make it a vector q_a of dimension $4m + 1$,

$$q_a = \begin{pmatrix} q \\ 0_{2m+1} \end{pmatrix}.$$

In order to solve our dual program, we apply ADMM to the quadratic functional

$$\frac{1}{2}x^\top P_a x + q_a^\top x,$$

subject to the constraints

$$Ax = c, \quad x \geq 0,$$

with P_a, q_a, A, b and x , as above.

Since for an optimal solution with $\epsilon > 0$ we must have $\gamma = 0$ (from the KKT conditions), we can solve the dual problem with the following set of constraints only involving the Lagrange multipliers $(\lambda, \mu, \alpha, \beta)$,

$$\begin{aligned} \sum_{i=1}^m \lambda_i - \sum_{i=1}^m \mu_i &= 0 \\ \sum_{i=1}^m \lambda_i + \sum_{i=1}^m \mu_i &= C\nu \\ \lambda + \alpha &= \frac{C}{m}, \quad \mu + \beta = \frac{C}{m}, \end{aligned}$$

which corresponds to the $(2m + 2) \times 4m$ A_2 given by

$$A_2 = \begin{pmatrix} \mathbf{1}_m^\top & -\mathbf{1}_m^\top & 0_m^\top & 0_m^\top \\ \mathbf{1}_m^\top & \mathbf{1}_m^\top & 0_m^\top & 0_m^\top \\ I_m & 0_{m,m} & I_m & 0_{m,m} \\ 0_{m,m} & I_m & 0_{m,m} & I_m \end{pmatrix}.$$

We leave it as an exercise to show that A_2 has rank $2m + 2$. We define the vector c_2 (of dimension $2m + 2$) as

$$c_2 = c = \begin{pmatrix} 0 \\ C\nu \\ \frac{C}{m}\mathbf{1}_{2m} \end{pmatrix}.$$

Since there are $4m$ Lagrange multipliers $(\lambda, \mu, \alpha, \beta)$, we need to pad the $2m \times 2m$ matrix P with zeros to make it into a $4m \times 4m$ matrix

$$P_{2a} = \begin{pmatrix} P & 0_{2m,2m} \\ 0_{2m,2m} & 0_{2m,2m} \end{pmatrix}.$$

Similarly, we pad q with zeros to make it a vector q_{2a} of dimension $4m$,

$$q_{2a} = \begin{pmatrix} q \\ 0_{2m} \end{pmatrix}.$$

We implemented the above methods in **Matlab**; see Appendix B, Section B.4. Choosing $C = m$ is typically a good choice because then the values of λ_i and μ_j are not too small ($C/m = 1$). If C is chosen too small, we found that numerical instability increases drastically and very poor results are obtained. Increasing C tends to encourage sparsity.

We ran our **Matlab** implementation of the above method on the set of 50 points generated at random by the program shown below with $C = 50$ and various values of ν starting with $\nu = 0.03$:

```
X13 = 15*randn(50,1);
ww13 = 1;
y13 = X13*ww13 + 10*randn(50,1) + 20;
[~,~,~,~,~,~,~,~,w1] = runuregb(rho,0.03,X13,y13,50)
```

Figure 56.11 shows the result of running the program with $\nu = 0.03$. We have $p_f = 0$, $q_f = 0$, $p_m = 2$ and $q_m = 1$. There are 47 points strictly inside the slab. The slab is large enough to contain all the data points, so none of them is considered an error.

The next value of ν is $\nu = 0.21$, see Figure 56.12. We have $p_f = 4$, $q_f = 5$, $p_m = 6$ and $q_m = 6$. There are 38 points strictly inside the slab.

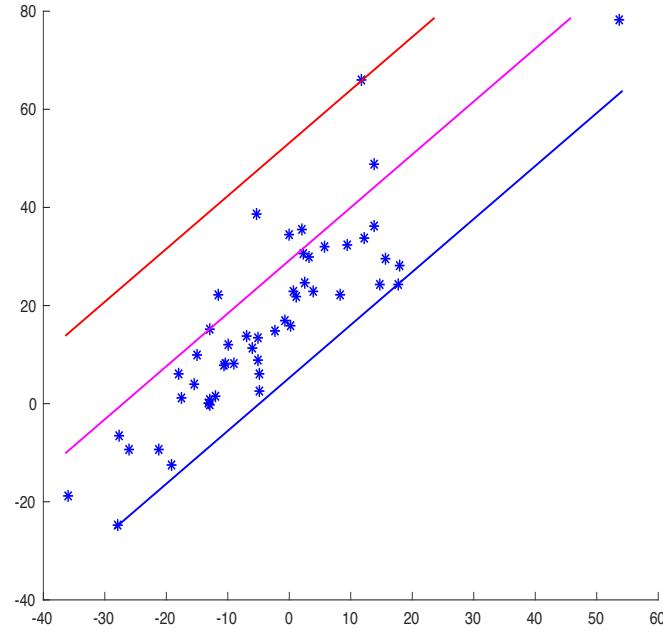

Figure 56.11: Running ν -SV regression on a set of 50 points; $\nu = 0.03$.

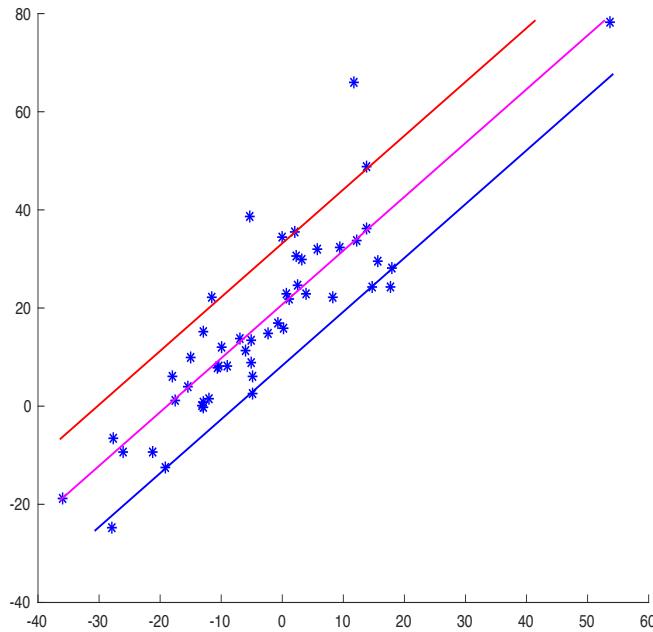

Figure 56.12: Running ν -SV regression on a set of 50 points; $\nu = 0.21$.

The next value of ν is $\nu = 0.5$, see Figure 56.13. We have $p_f = 12$, $q_f = 12$, $p_m = 13$ and

$q_m = 14$. There are 23 points strictly inside the slab.

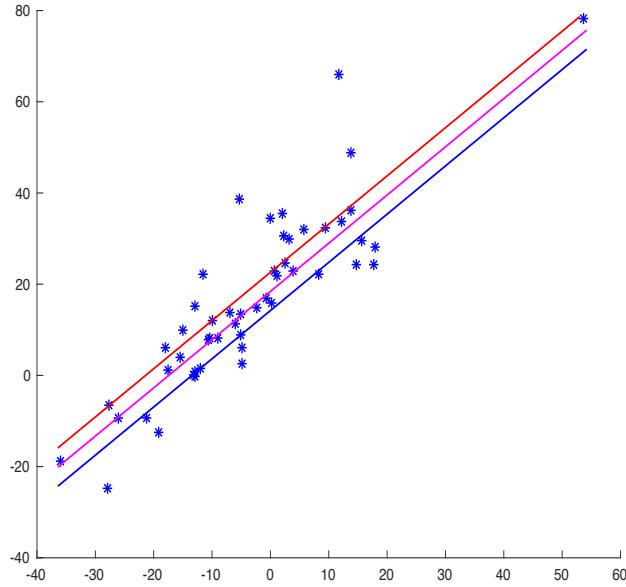

Figure 56.13: Running ν -SV regression on a set of 50 points; $\nu = 0.5$.

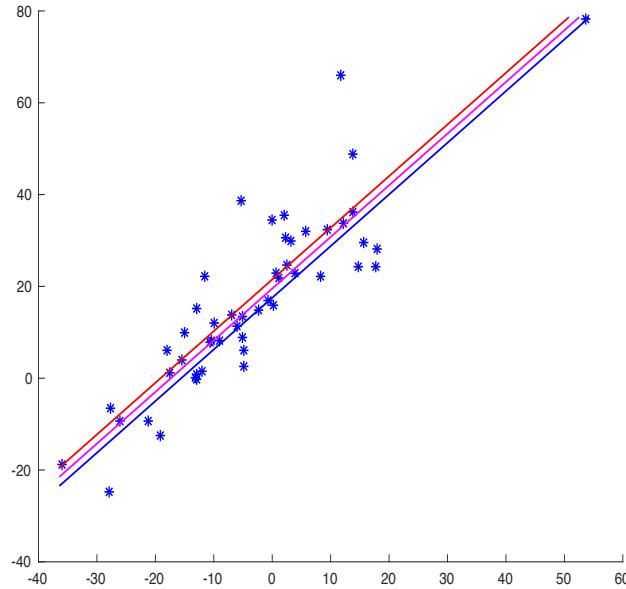

Figure 56.14: Running ν -SV regression on a set of 50 points; $\nu = 0.7$.

The next value of ν is $\nu = 0.7$, see Figure 56.14. We have $p_f = 17$, $q_f = 17$, $p_m = 18$ and

$q_m = 19$. There are 13 points strictly inside the slab.

The last value of ν is $\nu = 0.97$, see Figure 56.15. We have $p_f = 23, q_f = 24, p_m = 25$ and $q_m = 25$. There are 0 points strictly inside the slab. The slab is so narrow that it does not contain any of the points x_i in it. Running the program with any value $\nu > 0.97$ yields $\epsilon = 0$.

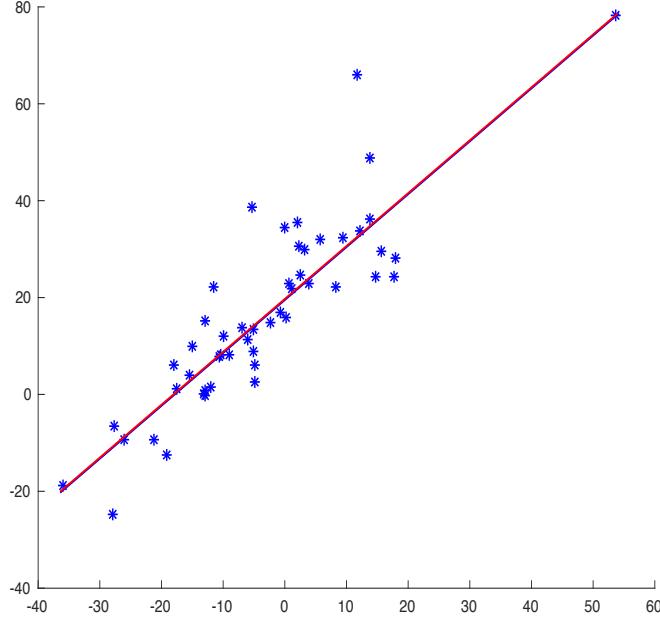

Figure 56.15: Running ν -SV regression on a set of 50 points; $\nu = 0.97$.

56.4 Kernel ν -SV Regression

Since the formulae for w , b , and $f(x)$,

$$\begin{aligned} w &= \sum_{i=1}^m (\mu_i - \lambda_i) x_i \\ b &= \frac{1}{2} (y_{i_0} + y_{j_0} - w^\top (x_{i_0} + x_{j_0})) \\ f(x) &= \sum_{i=1}^m (\mu_i - \lambda_i) x_i^\top x + b, \end{aligned}$$

only involve inner products among the data points x_i and x , and since the objective function $-G(\alpha, \mu)$ of the dual program also only involves inner products among the data points x_i , we can kernelize the ν -SV regression method.

As in the previous section, we assume that our data points $\{x_1, \dots, x_m\}$ belong to a set \mathcal{X} and we pretend that we have feature space $(F, \langle -, - \rangle)$ and a feature embedding map $\varphi: \mathcal{X} \rightarrow F$, but we only have access to the kernel function $\kappa(x_i, x_j) = \langle \varphi(x_i), \varphi(x_j) \rangle$. We wish to perform ν -SV regression in the feature space F on the data set $\{(\varphi(x_1), y_1), \dots, (\varphi(x_m), y_m)\}$. Going over the previous computation, we see that the primal program is given by

Program kernel ν -SV Regression:

$$\text{minimize } \frac{1}{2} \langle w, w \rangle + C \left(\nu \epsilon + \frac{1}{m} \sum_{i=1}^m (\xi_i + \xi'_i) \right)$$

subject to

$$\begin{aligned} \langle w, \varphi(x_i) \rangle + b - y_i &\leq \epsilon + \xi_i, & \xi_i &\geq 0 & i = 1, \dots, m \\ -\langle w, \varphi(x_i) \rangle - b + y_i &\leq \epsilon + \xi'_i, & \xi'_i &\geq 0 & i = 1, \dots, m \\ \epsilon &\geq 0, \end{aligned}$$

minimizing over the variables w, ϵ, b, ξ , and ξ' .

The Lagrangian is given by

$$\begin{aligned} L(w, b, \lambda, \mu, \gamma, \xi, \xi', \epsilon, \alpha, \beta) &= \frac{1}{2} \langle w, w \rangle + \left\langle w, \sum_{i=1}^m (\lambda_i - \mu_i) \varphi(x_i) \right\rangle \\ &+ \epsilon \left(C\nu - \gamma - \sum_{i=1}^m (\lambda_i + \mu_i) \right) + \sum_{i=1}^m \xi_i \left(\frac{C}{m} - \lambda_i - \alpha_i \right) \\ &+ \sum_{i=1}^m \xi'_i \left(\frac{C}{m} - \mu_i - \beta_i \right) + b \left(\sum_{i=1}^m (\lambda_i - \mu_i) \right) - \sum_{i=1}^m (\lambda_i - \mu_i) y_i. \end{aligned}$$

Setting the gradient $\nabla L_{w,\epsilon,b,\xi,\xi'}$ of the Lagrangian to zero, we also obtain the equations

$$\begin{aligned} w &= \sum_{i=1}^m (\mu_i - \lambda_i) \varphi(x_i), & (*_w) \\ \sum_{i=1}^m \lambda_i - \sum_{i=1}^m \mu_i &= 0 \\ \sum_{i=1}^m \lambda_i + \sum_{i=1}^m \mu_i + \gamma &= C\nu \\ \lambda + \alpha &= \frac{C}{m}, \quad \mu + \beta = \frac{C}{m}. \end{aligned}$$

Using the above equations, we find that the dual function G is independent of the variables β, α, β , and we obtain the following dual program:

Dual Program kernel ν -SV Regression:

$$\text{minimize} \quad \frac{1}{2} \sum_{i,j=1}^m (\lambda_i - \mu_i)(\lambda_j - \mu_j) \kappa(x_i, x_j) + \sum_{i=1}^m (\lambda_i - \mu_i)y_i$$

subject to

$$\begin{aligned} \sum_{i=1}^m \lambda_i - \sum_{i=1}^m \mu_i &= 0 \\ \sum_{i=1}^m \lambda_i + \sum_{i=1}^m \mu_i &\leq C\nu \\ 0 \leq \lambda_i &\leq \frac{C}{m}, \quad 0 \leq \mu_i \leq \frac{C}{m}, \quad i = 1, \dots, m, \end{aligned}$$

minimizing over α and μ .

Everything we said before also applies to the kernel ν -SV regression method, except that x_i is replaced by $\varphi(x_i)$ and that the inner product $\langle -, - \rangle$ must be used, and we have the formulae

$$\begin{aligned} w &= \sum_{i=1}^m (\mu_i - \lambda_i) \varphi(x_i) \\ b &= \frac{1}{2} \left(y_{i_0} + y_{j_0} - \sum_{i=1}^m (\mu_i - \lambda_i) (\kappa(x_i, x_{i_0}) + \kappa(x_i, x_{j_0})) \right) \\ f(x) &= \sum_{i=1}^m (\mu_i - \lambda_i) \kappa(x_i, x) + b, \end{aligned}$$

expressions that only involve κ .

Remark: There is a variant of ν -SV regression obtained by setting $\nu = 0$ and holding $\epsilon > 0$ fixed. This method is called ϵ -SV regression or (linear) ϵ -insensitive SV regression. The corresponding optimization program is

Program ϵ -SV Regression:

$$\text{minimize} \quad \frac{1}{2} w^\top w + \frac{C}{m} \sum_{i=1}^m (\xi_i + \xi'_i)$$

subject to

$$\begin{aligned} w^\top x_i + b - y_i &\leq \epsilon + \xi_i, \quad \xi_i \geq 0 \quad i = 1, \dots, m \\ -w^\top x_i - b + y_i &\leq \epsilon + \xi'_i, \quad \xi'_i \geq 0 \quad i = 1, \dots, m, \end{aligned}$$

minimizing over the variables w, b, ξ , and ξ' , holding ϵ fixed.

It is easy to see that the dual program is

Dual Program ϵ -SV Regression:

$$\text{minimize} \quad \frac{1}{2} \sum_{i,j=1}^m (\lambda_i - \mu_i)(\lambda_j - \mu_j) x_i^\top x_j + \sum_{i=1}^m (\lambda_i - \mu_i)y_i + \epsilon \sum_{i=1}^m (\lambda_i + \mu_i)$$

subject to

$$\begin{aligned} \sum_{i=1}^m \lambda_i - \sum_{i=1}^m \mu_i &= 0 \\ 0 \leq \lambda_i \leq \frac{C}{m}, \quad 0 \leq \mu_i \leq \frac{C}{m}, \quad i &= 1, \dots, m, \end{aligned}$$

minimizing over α and μ .

The constraint

$$\sum_{i=1}^m \lambda_i + \sum_{i=1}^m \mu_i \leq C\nu$$

is gone but the extra term $\epsilon \sum_{i=1}^m (\lambda_i + \mu_i)$ has been added to the dual function, to prevent λ_i and μ_i from blowing up.

There is an obvious kernelized version of ϵ -SV regression. It is easy to show that ν -SV regression subsumes ϵ -SV regression, in the sense that if ν -SV regression succeeds and yields $w, b, \epsilon > 0$, then ϵ -SV regression with the same C and the same value of ϵ also succeeds and returns the same pair (w, b) . For more details on these methods, see Schölkopf, Smola, Williamson, and Bartlett [147].

Remark: The linear penalty function $\sum_{i=1}^m (\xi_i + \xi'_i)$ can be replaced by the quadratic penalty function $\sum_{i=1}^m (\xi_i^2 + \xi'^2_i)$; see Shawe-Taylor and Christianini [159] (Chapter 7). In this case, it is easy to see that for an optimal solution we must have $\xi_i \geq 0$ and $\xi'_i \geq 0$, so we may omit the constraints $\xi_i \geq 0$ and $\xi'_i \geq 0$. We must also have $\gamma = 0$ so we omit the variable γ as well. It can be shown that $\xi = (m/2C)\lambda$ and $\xi' = (m/2C)\mu$. This problem is very similar to the Soft Margin SVM (SVM_{s4}) discussed in Section 54.13.

56.5 ν -Regression Version 2; Penalizing b

Yet another variant of ν -SV regression is to add the term $\frac{1}{2}b^2$ to the objective function. We will see that solving the dual not only determines w but also b and ϵ (provided a mild condition on ν). We wish to solve the following program:

Program ν -SV Regression Version 2

$$\text{minimize} \quad \frac{1}{2}w^\top w + \frac{1}{2}b^2 + C\left(\nu\epsilon + \frac{1}{m}\sum_{i=1}^m(\xi_i + \xi'_i)\right)$$

subject to

$$\begin{aligned} w^\top x_i + b - y_i &\leq \epsilon + \xi_i, \quad \xi_i \geq 0 \quad i = 1, \dots, m \\ -w^\top x_i - b + y_i &\leq \epsilon + \xi'_i, \quad \xi'_i \geq 0 \quad i = 1, \dots, m, \end{aligned}$$

minimizing over the variables w, b, ϵ, ξ , and ξ' . The constraint $\epsilon \geq 0$ is omitted since the problem has no solution if $\epsilon < 0$.

We leave it as an exercise to show that the new Lagrangian is

$$\begin{aligned} L(w, b, \lambda, \mu, \xi, \xi', \epsilon, \alpha, \beta) &= \frac{1}{2}w^\top w + w^\top \left(\sum_{i=1}^m (\lambda_i - \mu_i)x_i \right) \\ &+ \epsilon \left(C\nu - \sum_{i=1}^m (\lambda_i + \mu_i) \right) + \sum_{i=1}^m \xi_i \left(\frac{C}{m} - \lambda_i - \alpha_i \right) \\ &+ \sum_{i=1}^m \xi'_i \left(\frac{C}{m} - \mu_i - \beta_i \right) + \frac{1}{2}b^2 + b \left(\sum_{i=1}^m (\lambda_i - \mu_i) \right) - \sum_{i=1}^m (\lambda_i - \mu_i)y_i. \end{aligned}$$

If we set the Laplacian $\nabla L_{w, \epsilon, b, \xi, \xi'}$ to zero we obtain the equations

$$\begin{aligned} w &= \sum_{i=1}^m (\mu_i - \lambda_i)x_i = X^\top(\mu - \lambda) & (*_w) \\ C\nu - \sum_{i=1}^m (\lambda_i + \mu_i) &= 0 \\ b + \sum_{i=1}^m (\lambda_i - \mu_i) &= 0 \\ \frac{C}{m} - \lambda - \alpha &= 0, \quad \frac{C}{m} - \mu - \beta = 0. \end{aligned}$$

We obtain the new equation

$$b = -\sum_{i=1}^m (\lambda_i - \mu_i) = -(\mathbf{1}_m^\top \lambda - \mathbf{1}_m^\top \mu) \quad (*_b)$$

determining b , which replaces the equation

$$\sum_{i=1}^m \lambda_i - \sum_{i=1}^m \mu_i = 0.$$

Plugging back w from $(*_w)$ and b from $(*_b)$ into the Lagrangian we get

$$\begin{aligned} G(\lambda, \mu, \alpha, \beta) &= -\frac{1}{2} (\lambda^\top \quad \mu^\top) P \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - q^\top \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + \frac{1}{2} b^2 - b^2 \\ &= -\frac{1}{2} (\lambda^\top \quad \mu^\top) P \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - q^\top \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - \frac{1}{2} b^2 \\ &= -\frac{1}{2} (\lambda^\top \quad \mu^\top) \left(P + \begin{pmatrix} \mathbf{1}_m \mathbf{1}_m^\top & -\mathbf{1}_m \mathbf{1}_m^\top \\ -\mathbf{1}_m \mathbf{1}_m^\top & \mathbf{1}_m \mathbf{1}_m^\top \end{pmatrix} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - q^\top \begin{pmatrix} \lambda \\ \mu \end{pmatrix}, \end{aligned}$$

with

$$P = \begin{pmatrix} XX^\top & -XX^\top \\ -XX^\top & XX^\top \end{pmatrix} = \begin{pmatrix} \mathbf{K} & -\mathbf{K} \\ -\mathbf{K} & \mathbf{K} \end{pmatrix}$$

and

$$q = \begin{pmatrix} y \\ -y \end{pmatrix}.$$

The new dual program is

Dual Program ν -SV Regression Version 2

$$\text{minimize } \frac{1}{2} (\lambda^\top \quad \mu^\top) \left(P + \begin{pmatrix} \mathbf{1}_m \mathbf{1}_m^\top & -\mathbf{1}_m \mathbf{1}_m^\top \\ -\mathbf{1}_m \mathbf{1}_m^\top & \mathbf{1}_m \mathbf{1}_m^\top \end{pmatrix} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + q^\top \begin{pmatrix} \lambda \\ \mu \end{pmatrix}$$

subject to

$$\begin{aligned} \sum_{i=1}^m \lambda_i + \sum_{i=1}^m \mu_i &= C\nu \\ 0 \leq \lambda_i \leq \frac{C}{m}, \quad 0 \leq \mu_i \leq \frac{C}{m}, \quad i &= 1, \dots, m. \end{aligned}$$

Definition 56.1 and Definition 56.2 are unchanged. We have the following version of Proposition 56.2 showing that p_f, q_f, p_m and q_m have direct influence on the choice of ν .

Proposition 56.7. (1) Let p_f be the number of points x_i such that $\lambda_i = C/m$, and let q_f be the number of points x_i such that $\mu_i = C/m$. We have $p_f + q_f \leq m\nu$.

(2) Let p_m be the number of points x_i such that $\lambda_i > 0$, and let q_m be the number of points x_i such that $\mu_i > 0$. We have $p_m + q_m \geq m\nu$.

(3) If $p_f \geq 1$ or $q_f \geq 1$, then $\nu \geq 1/m$.

Proof. (1) Let K_λ and K_μ be the sets of indices corresponding to points failing the margin,

$$\begin{aligned} K_\lambda &= \{i \in \{1, \dots, m\} \mid \lambda_i = C/m\} \\ K_\mu &= \{i \in \{1, \dots, m\} \mid \mu_i = C/m\}. \end{aligned}$$

By definition $p_f = |K_\lambda|$, $q_f = |K_\mu|$. Since the equation

$$\sum_{i=1}^m \lambda_i + \sum_{j=1}^m \mu_j = C\nu$$

holds, by definition of K_λ and K_μ we have

$$(p_f + q_f) \frac{C}{m} = \sum_{i \in K_\lambda} \lambda_i + \sum_{j \in K_\mu} \mu_j \leq \sum_{i=1}^m \lambda_i + \sum_{j=1}^m \mu_j = C\nu,$$

which implies that

$$p_f + q_f \leq m\nu.$$

(2) Let $I_{\lambda>0}$ and $I_{\mu>0}$ be the sets of indices

$$\begin{aligned} I_{\lambda>0} &= \{i \in \{1, \dots, m\} \mid \lambda_i > 0\} \\ I_{\mu>0} &= \{i \in \{1, \dots, m\} \mid \mu_i > 0\}. \end{aligned}$$

By definition $p_m = |I_{\lambda>0}|$, $q_m = |I_{\mu>0}|$. We have

$$\sum_{i=1}^m \lambda_i + \sum_{j=1}^m \mu_j = \sum_{i \in I_{\lambda>0}} \lambda_i + \sum_{j \in I_{\mu>0}} \mu_j = C\nu.$$

Since $\lambda_i \leq C/m$ and $\mu_j \leq C/m$, we obtain

$$C\nu \leq (p_m + q_m) \frac{C}{m},$$

that is, $p_m + q_m \geq m\nu$.

(3) follows immediately from (1). \square

Proposition 56.7 yields the following bounds on ν :

$$\frac{p_f + q_f}{m} \leq \nu \leq \frac{p_m + q_m}{m}.$$

Again, the smaller ν is, the wider the ϵ -slab is, and the larger ν is, the narrower the ϵ -slab is.

Remark: It can be shown that for any optimal solution with $w \neq 0$ and $\epsilon > 0$, if the inequalities $(p_f + q_f)/m < \nu < 1$ hold, then some point x_i is a support vector. The proof is essentially Case 1b in the proof of Proposition 56.4. We leave the details as an exercise.

The new dual program is solved using ADMM. The $(2m+1) \times 4m$ matrix A_3 corresponding to the equational constraints

$$\begin{aligned}\sum_{i=1}^m \lambda_i + \sum_{i=1}^m \mu_i &= C\nu \\ \lambda + \alpha &= \frac{C}{m}, \quad \mu + \beta = \frac{C}{m},\end{aligned}$$

is given by

$$A_3 = \begin{pmatrix} \mathbf{1}_m^\top & \mathbf{1}_m^\top & 0_m^\top & 0_m^\top \\ I_m & 0_{m,m} & I_m & 0_{m,m} \\ 0_{m,m} & I_m & 0_{m,m} & I_m \end{pmatrix}.$$

We leave it as an exercise to show that A_3 has rank $2m+1$. We define the vector c_3 (of dimension $2m+1$) as

$$c_3 = \begin{pmatrix} C\nu \\ \frac{C}{m} \mathbf{1}_{2m} \end{pmatrix}.$$

Since there are $4m$ Lagrange multipliers $(\lambda, \mu, \alpha, \beta)$, we need to pad the $2m \times 2m$ matrix $P_3 = P + \begin{pmatrix} \mathbf{1}_m \mathbf{1}_m^\top & -\mathbf{1}_m \mathbf{1}_m^\top \\ -\mathbf{1}_m \mathbf{1}_m^\top & \mathbf{1}_m \mathbf{1}_m^\top \end{pmatrix}$ with zeros to make it into a $4m \times 4m$ matrix

$$P_{3a} = \begin{pmatrix} P_3 & 0_{2m,2m} \\ 0_{2m,2m} & 0_{2m,2m} \end{pmatrix}.$$

Similarly, we pad q with zeros to make it a vector q_{3a} of dimension $4m$,

$$q_{3a} = \begin{pmatrix} q \\ 0_{2m} \end{pmatrix}.$$

It remains to compute ϵ . There are two methods to do this.

The first method assumes the **Standard Margin Hypothesis**, which is that there is some i_0 such that $0 < \lambda_{i_0} < C/m$ or there is some j_0 such that $0 < \mu_{j_0} < C/m$; in other words, there is some support vector of type 1. By the complementary slackness conditions, $\xi_{i_0} = 0$ or $\xi'_{j_0} = 0$, so we have either $w^\top x_{i_0} + b - y_{i_0} = \epsilon$ or $-w^\top x_{j_0} - b + y_{j_0} = \epsilon$, which determines ϵ .

Due to numerical instability, when writing a computer program it is preferable to compute the lists of indices I_λ and I_μ given by

$$\begin{aligned}I_\lambda &= \{i \in \{1, \dots, m\} \mid 0 < \lambda_i < C/m\} \\ I_\mu &= \{j \in \{1, \dots, m\} \mid 0 < \mu_j < C/m\}.\end{aligned}$$

Then it is easy to see that we can compute ϵ using the following averaging formulae: if $I_\lambda \neq \emptyset$, then

$$\epsilon = w^\top \left(\sum_{i \in I_\lambda} x_i \right) / |I_\lambda| + b - \left(\sum_{i \in I_\lambda} y_i \right) / |I_\lambda|,$$

and if $I_\mu \neq \emptyset$, then

$$\epsilon = -w^\top \left(\sum_{j \in I_\mu} x_j \right) / |I_\mu| - b + \left(\sum_{i \in I_\mu} y_i \right) / |I_\mu|.$$

The second method uses duality. Under a mild condition, expressing that the duality gap is zero, we can determine ϵ in terms of λ, μ and b . This is because points x_i that fail the margin, which means that $\lambda_i = C/m$ or $\mu_i = C/m$, are the only points for which $\xi_i > 0$ or $\xi'_i > 0$. But in this case we have an active constraint

$$w^\top x_i + b - y_i = \epsilon + \xi_i \quad (*_\xi)$$

or

$$-w^\top x_i - b + y_i = \epsilon + \xi'_i, \quad (*_{\xi'})$$

so ξ_i and ξ'_i can be expressed in terms of w and b . Since the duality gap is zero for an optimal solution, the optimal value of the primal is equal to the optimal value of the dual. Using the fact that

$$\begin{aligned} w &= X^\top (\mu - \lambda) \\ b &= -(\mathbf{1}_m^\top \lambda - \mathbf{1}_m^\top \mu) = (\lambda^\top \ \mu^\top) \begin{pmatrix} -\mathbf{1}_m \\ \mathbf{1}_m \end{pmatrix} \end{aligned}$$

we obtain an expression for the optimal value of the primal. First we have

$$\begin{aligned} \frac{1}{2} w^\top w + \frac{1}{2} b^2 &= \frac{1}{2} (\lambda^\top - \mu^\top) X X^\top (\lambda - \mu) + \frac{1}{2} (\lambda^\top \ \mu^\top) \begin{pmatrix} \mathbf{1}_m \mathbf{1}_m^\top & -\mathbf{1}_m \mathbf{1}_m^\top \\ -\mathbf{1}_m \mathbf{1}_m^\top & \mathbf{1}_m \mathbf{1}_m^\top \end{pmatrix} \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ &= \frac{1}{2} (\lambda^\top \ \mu^\top) \left(P + \begin{pmatrix} \mathbf{1}_m \mathbf{1}_m^\top & -\mathbf{1}_m \mathbf{1}_m^\top \\ -\mathbf{1}_m \mathbf{1}_m^\top & \mathbf{1}_m \mathbf{1}_m^\top \end{pmatrix} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}, \end{aligned}$$

with

$$P = \begin{pmatrix} X X^\top & -X X^\top \\ -X X^\top & X X^\top \end{pmatrix}.$$

Let K_λ and K_μ be the sets of indices corresponding to points failing the margin,

$$\begin{aligned} K_\lambda &= \{i \in \{1, \dots, m\} \mid \lambda_i = C/m\} \\ K_\mu &= \{i \in \{1, \dots, m\} \mid \mu_i = C/m\}. \end{aligned}$$

Because $\lambda_i \mu_i = 0$, the sets K_λ and K_μ are disjoint. Observe that from Definition 56.2 we have $p_f = |K_\lambda|$ and $q_f = |K_\mu|$. Then by (\ast_ξ) and $(\ast_{\xi'})$, we have

$$\begin{aligned} \sum_{i=1}^m (\xi_i + \xi'_i) &= \sum_{i \in K_\lambda} \xi_i + \sum_{j \in K_\mu} \xi'_j \\ &= \sum_{i \in K_\lambda} (w^\top x_i + b - y_i - \epsilon) + \sum_{j \in K_\mu} (-w^\top x_j - b + y_j - \epsilon) \\ &= w^\top \left(\sum_{i \in K_\lambda} x_i - \sum_{j \in K_\mu} x_j \right) - \sum_{i \in K_\lambda} y_i + \sum_{j \in K_\mu} y_j + (p_f - q_f)b - (p_f + q_f)\epsilon. \end{aligned}$$

The optimal value of the dual is given by

$$-\frac{1}{2} (\lambda^\top \quad \mu^\top) \left(P + \begin{pmatrix} \mathbf{1}_m \mathbf{1}_m^\top & -\mathbf{1}_m \mathbf{1}_m^\top \\ -\mathbf{1}_m \mathbf{1}_m^\top & \mathbf{1}_m \mathbf{1}_m^\top \end{pmatrix} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - q^\top \begin{pmatrix} \lambda \\ \mu \end{pmatrix},$$

with

$$q = \begin{pmatrix} y \\ -y \end{pmatrix}.$$

Expressing that the duality gap is zero we have

$$\begin{aligned} \frac{1}{2} w^\top w + \frac{1}{2} b^2 + C\nu\epsilon + \frac{C}{m} \sum_{i=1}^m (\xi_i + \xi'_i) \\ = -\frac{1}{2} (\lambda^\top \quad \mu^\top) \left(P + \begin{pmatrix} \mathbf{1}_m \mathbf{1}_m^\top & -\mathbf{1}_m \mathbf{1}_m^\top \\ -\mathbf{1}_m \mathbf{1}_m^\top & \mathbf{1}_m \mathbf{1}_m^\top \end{pmatrix} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - q^\top \begin{pmatrix} \lambda \\ \mu \end{pmatrix}, \end{aligned}$$

that is,

$$\begin{aligned} \frac{1}{2} (\lambda^\top \quad \mu^\top) \left(P + \begin{pmatrix} \mathbf{1}_m \mathbf{1}_m^\top & -\mathbf{1}_m \mathbf{1}_m^\top \\ -\mathbf{1}_m \mathbf{1}_m^\top & \mathbf{1}_m \mathbf{1}_m^\top \end{pmatrix} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + C\nu\epsilon \\ + \frac{C}{m} \left(w^\top \left(\sum_{i \in K_\lambda} x_i - \sum_{j \in K_\mu} x_j \right) - \sum_{i \in K_\lambda} y_i + \sum_{j \in K_\mu} y_j + (p_f - q_f)b - (p_f + q_f)\epsilon \right) \\ = -\frac{1}{2} (\lambda^\top \quad \mu^\top) \left(P + \begin{pmatrix} \mathbf{1}_m \mathbf{1}_m^\top & -\mathbf{1}_m \mathbf{1}_m^\top \\ -\mathbf{1}_m \mathbf{1}_m^\top & \mathbf{1}_m \mathbf{1}_m^\top \end{pmatrix} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - q^\top \begin{pmatrix} \lambda \\ \mu \end{pmatrix}. \end{aligned}$$

Solving for ϵ we get

$$\begin{aligned} C \left(\nu - \frac{p_f + q_f}{m} \right) \epsilon &= - (\lambda^\top \quad \mu^\top) \left(P + \begin{pmatrix} \mathbf{1}_m \mathbf{1}_m^\top & -\mathbf{1}_m \mathbf{1}_m^\top \\ -\mathbf{1}_m \mathbf{1}_m^\top & \mathbf{1}_m \mathbf{1}_m^\top \end{pmatrix} \right) \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - (y^\top \quad -y^\top) \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \\ &\quad - \frac{C}{m} \left(w^\top \left(\sum_{i \in K_\lambda} x_i - \sum_{j \in K_\mu} x_j \right) - \sum_{i \in K_\lambda} y_i + \sum_{j \in K_\mu} y_j + (p_f - q_f)b \right), \end{aligned}$$

so we get

$$\begin{aligned}\epsilon = & -\left(\frac{m}{C} \begin{pmatrix} (\lambda^\top & \mu^\top) \\ \end{pmatrix} \begin{pmatrix} P + \begin{pmatrix} \mathbf{1}_m \mathbf{1}_m^\top & -\mathbf{1}_m \mathbf{1}_m^\top \\ -\mathbf{1}_m \mathbf{1}_m^\top & \mathbf{1}_m \mathbf{1}_m^\top \end{pmatrix} \end{pmatrix} \begin{pmatrix} \lambda \\ \mu \end{pmatrix} + (y^\top & -y^\top) \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \right) \\ & + w^\top \left(\sum_{i \in K_\lambda} x_i - \sum_{j \in K_\mu} x_j \right) - \sum_{i \in K_\lambda} y_i + \sum_{j \in K_\mu} y_j + (p_f - q_f)b \Bigg) \Bigg/ (m\nu - p_f - q_f).\end{aligned}$$

Using the equations

$$\begin{aligned}w &= X^\top(\mu - \lambda) \\ b &= -(\mathbf{1}_m^\top \lambda - \mathbf{1}_m^\top \mu) = (\lambda^\top & \mu^\top) \begin{pmatrix} -\mathbf{1}_m \\ \mathbf{1}_m \end{pmatrix},\end{aligned}$$

we see that ϵ is determined by λ and μ provided that $(p_f + q_f)/m < \nu$.

By Proposition 56.7(1),

$$\frac{p_f + q_f}{m} \leq \nu,$$

therefore the condition $(p_f + q_f)/m < \nu$ is very natural.

We have implemented this method in **Matlab**, and we have observed that for some examples the choice of ν caused the equation $\nu(p_f + q_f) = m$ to hold. In such cases, running the program again with a slightly perturbed value of ν always succeeded.

The other observation we made is that b tends to be smaller and ϵ tends to be bigger in ν -SV Regression Version 2, so the fit is actually not as good as in ν -SV Regression without penalizing b . Figure 56.16 shows the result of running our program on the data set of Section 56.3. Compare with Figure 56.13.

56.6 Summary

The main concepts and results of this chapter are listed below:

- ν -support vector regression (ν -SV regression).
- Regression estimate.
- Kernel ν -SV regression.
- ϵ -SV regression, ϵ -insensitive SV regression,
- ν -SV regression Version 2; penalizing b .

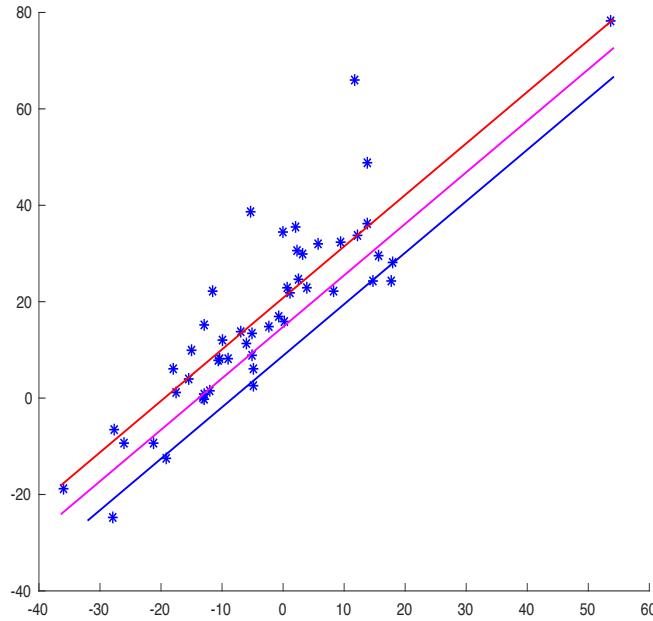

Figure 56.16: Running ν -SV regression version 2 on a set of 50 points; $\nu = 0.5$.

56.7 Problems

Problem 56.1. Prove that if ν -SV regression succeeds and yields $w, b, \epsilon > 0$, then ϵ -SV regression with the same C and the same value of ϵ also succeeds and returns the same pair (w, b) .

Problem 56.2. Prove the formulae

$$b = \left(\left(\sum_{i_0 \in I_\lambda} y_{i_0} \right) / |I_\lambda| + \left(\sum_{j_0 \in I_\mu} y_{j_0} \right) / |I_\mu| - w^\top \left(\left(\sum_{i_0 \in I_\lambda} x_{i_0} \right) / |I_\lambda| + \left(\sum_{j_0 \in I_\mu} x_{j_0} \right) / |I_\mu| \right) \right) / 2$$

$$\epsilon = \left(\left(\sum_{j_0 \in I_\mu} y_{j_0} \right) / |I_\mu| - \left(\sum_{i_0 \in I_\lambda} y_{i_0} \right) / |I_\lambda| + w^\top \left(\left(\sum_{i_0 \in I_\lambda} x_{i_0} \right) / |I_\lambda| - \left(\sum_{j_0 \in I_\mu} x_{j_0} \right) / |I_\mu| \right) \right) / 2$$

stated just before Proposition 56.6.

Problem 56.3. Give the details of the proof of Proposition 56.6. In particular, prove that

$$C \left(\nu - \frac{p_f + q_f}{m} \right) \epsilon = - (\lambda^\top \quad \mu^\top) P \begin{pmatrix} \lambda \\ \mu \end{pmatrix} - (y^\top \quad -y^\top) \begin{pmatrix} \lambda \\ \mu \end{pmatrix}$$

$$- \frac{C}{m} \left(w^\top \left(\sum_{i \in K_\lambda} x_i - \sum_{j \in K_\mu} x_j \right) - \sum_{i \in K_\lambda} y_i + \sum_{j \in K_\mu} y_j + (p_f - q_f)b \right).$$

Problem 56.4. Prove that the matrices

$$A = \begin{pmatrix} \mathbf{1}_m^\top & -\mathbf{1}_m^\top & 0_m^\top & 0_m^\top & 0 \\ \mathbf{1}_m^\top & \mathbf{1}_m^\top & 0_m^\top & 0_m^\top & 1 \\ I_m & 0_{m,m} & I_m & 0_{m,m} & 0_m \\ 0_{m,m} & I_m & 0_{m,m} & I_m & 0_m \end{pmatrix}, \quad A_2 = \begin{pmatrix} \mathbf{1}_m^\top & -\mathbf{1}_m^\top & 0_m^\top & 0_m^\top \\ \mathbf{1}_m^\top & \mathbf{1}_m^\top & 0_m^\top & 0_m^\top \\ I_m & 0_{m,m} & I_m & 0_{m,m} \\ 0_{m,m} & I_m & 0_{m,m} & I_m \end{pmatrix}$$

have rank $2m + 2$.

Problem 56.5. Derive the version of ν -SV regression in which the linear penalty function $\sum_{i=1}^m (\xi_i + \xi'_i)$ is replaced by the quadratic penalty function $\sum_{i=1}^m (\xi_i^2 + \xi'^2_i)$. Derive the dual program.

Problem 56.6. The linear penalty function $\sum_{i=1}^m (\xi_i + \xi'_i)$ can be replaced by the quadratic penalty function $\sum_{i=1}^m (\xi_i^2 + \xi'^2_i)$. Prove that for an optimal solution we must have $\xi_i \geq 0$ and $\xi'_i \geq 0$, so we may omit the constraints $\xi_i \geq 0$ and $\xi'_i \geq 0$. We must also have $\gamma = 0$ so we may omit the variable γ as well. Prove that $\xi = (m/2C)\lambda$ and $\xi' = (m/2C)\mu$. This problem is very similar to the Soft Margin SVM (SVM_{s4}) discussed in Section 54.13.

Problem 56.7. Consider the version of ν -SV regression in Section 56.5. Prove that for any optimal solution with $w \neq 0$ and $\epsilon > 0$, if the inequalities $(p_f + q_f)/m < \nu < 1$ hold, then some point x_i is a support vector.

Problem 56.8. Prove that the matrix

$$A_3 = \begin{pmatrix} \mathbf{1}_m^\top & \mathbf{1}_m^\top & 0_m^\top & 0_m^\top \\ I_m & 0_{m,m} & I_m & 0_{m,m} \\ 0_{m,m} & I_m & 0_{m,m} & I_m \end{pmatrix}$$

has rank $2m + 1$.

Problem 56.9. Consider the version of ν -SV regression in Section 56.5. Prove the following formulae: If $I_\lambda \neq \emptyset$, then

$$\epsilon = w^\top \left(\sum_{i \in I_\lambda} x_i \right) / |I_\lambda| + b - \left(\sum_{i \in I_\lambda} y_i \right) / |I_\lambda|,$$

and if $I_\mu \neq \emptyset$, then

$$\epsilon = -w^\top \left(\sum_{j \in I_\mu} x_j \right) / |I_\mu| - b + \left(\sum_{i \in I_\mu} y_i \right) / |I_\mu|.$$

Problem 56.10. Implement ν -Regression Version 2 described in Section 56.5. Run examples using both the original version and version 2 and compare the results.

Total Orthogonal Families in Hilbert Spaces

A.1 Total Orthogonal Families (Hilbert Bases), Fourier Coefficients

We conclude our quick tour of Hilbert spaces by showing that the notion of orthogonal basis can be generalized to Hilbert spaces. However, the useful notion is not the usual notion of a basis, but a notion which is an abstraction of the concept of Fourier series. Every element of a Hilbert space is the “sum” of its Fourier series.

Definition A.1. Given a Hilbert space E , a family $(u_k)_{k \in K}$ of nonnull vectors is an *orthogonal family* iff the u_k are pairwise orthogonal, i.e., $\langle u_i, u_j \rangle = 0$ for all $i \neq j$ ($i, j \in K$), and an *orthonormal family* iff $\langle u_i, u_j \rangle = \delta_{i,j}$, for all $i, j \in K$. A *total orthogonal family* (or *system*) or *Hilbert basis* is an orthogonal family that is dense in E . This means that for every $v \in E$, for every $\epsilon > 0$, there is some finite subset $I \subseteq K$ and some family $(\lambda_i)_{i \in I}$ of complex numbers, such that

$$\left\| v - \sum_{i \in I} \lambda_i u_i \right\| < \epsilon.$$

Given an orthogonal family $(u_k)_{k \in K}$, for every $v \in E$, for every $k \in K$, the scalar $c_k = \langle v, u_k \rangle / \|u_k\|^2$ is called the *k-th Fourier coefficient of v over $(u_k)_{k \in K}$* .

Remark: The terminology Hilbert basis is misleading because a *Hilbert basis* $(u_k)_{k \in K}$ is not necessarily a basis in the algebraic sense. Indeed, in general, $(u_k)_{k \in K}$ does not span E . Intuitively, it takes linear combinations of the u_k 's with infinitely many nonnull coefficients to span E . Technically, this is achieved in terms of limits. In order to avoid the confusion between bases in the algebraic sense and Hilbert bases, some authors refer to algebraic bases as *Hamel bases* and to total orthogonal families (or Hilbert bases) as *Schauder bases*.

Given an orthogonal family $(u_k)_{k \in K}$, for any finite subset I of K , we often call sums of the form $\sum_{i \in I} \lambda_i u_i$ *partial sums of Fourier series*, and if these partial sums converge to a limit denoted as $\sum_{k \in K} c_k u_k$, we call $\sum_{k \in K} c_k u_k$ a *Fourier series*.

However, we have to make sense of such sums! Indeed, when K is unordered or uncountable, the notion of limit or sum has not been defined. This can be done as follows (for more details, see Dixmier [51]):

Definition A.2. Given a normed vector space E (say, a Hilbert space), for any nonempty index set K , we say that a family $(u_k)_{k \in K}$ of vectors in E is *summable with sum $v \in E$* iff for every $\epsilon > 0$, there is some finite subset I of K , such that,

$$\left\| v - \sum_{j \in J} u_j \right\| < \epsilon$$

for every finite subset J with $I \subseteq J \subseteq K$. We say that the family $(u_k)_{k \in K}$ is *summable* iff there is some $v \in E$ such that $(u_k)_{k \in K}$ is summable with sum v . A family $(u_k)_{k \in K}$ is a *Cauchy family* iff for every $\epsilon > 0$, there is a finite subset I of K , such that,

$$\left\| \sum_{j \in J} u_j \right\| < \epsilon$$

for every finite subset J of K with $I \cap J = \emptyset$,

If $(u_k)_{k \in K}$ is summable with sum v , we usually denote v as $\sum_{k \in K} u_k$. The following technical proposition will be needed:

Proposition A.1. *Let E be a complete normed vector space (say, a Hilbert space).*

- (1) *For any nonempty index set K , a family $(u_k)_{k \in K}$ is summable iff it is a Cauchy family.*
- (2) *Given a family $(r_k)_{k \in K}$ of nonnegative reals $r_k \geq 0$, if there is some real number $B > 0$ such that $\sum_{i \in I} r_i < B$ for every finite subset I of K , then $(r_k)_{k \in K}$ is summable and $\sum_{k \in K} r_k = r$, where r is least upper bound of the set of finite sums $\sum_{i \in I} r_i$ ($I \subseteq K$).*

Proof. (1) If $(u_k)_{k \in K}$ is summable, for every finite subset I of K , let

$$u_I = \sum_{i \in I} u_i \quad \text{and} \quad u = \sum_{k \in K} u_k$$

For every $\epsilon > 0$, there is some finite subset I of K such that

$$\|u - u_I\| < \epsilon/2$$

for all finite subsets L such that $I \subseteq L \subseteq K$. For every finite subset J of K such that $I \cap J = \emptyset$, since $I \subseteq I \cup J \subseteq K$ and $I \cup J$ is finite, we have

$$\|u - u_{I \cup J}\| < \epsilon/2 \quad \text{and} \quad \|u - u_I\| < \epsilon/2,$$

and since

$$\|u_{I \cup J} - u_I\| \leq \|u_{I \cup J} - u\| + \|u - u_I\|$$

and $u_{I \cup J} - u_I = u_J$ since $I \cap J = \emptyset$, we get

$$\|u_J\| = \|u_{I \cup J} - u_I\| < \epsilon,$$

which is the condition for $(u_k)_{k \in K}$ to be a Cauchy family.

Conversely, assume that $(u_k)_{k \in K}$ is a Cauchy family. We define inductively a decreasing sequence (X_n) of subsets of E , each of diameter at most $1/n$, as follows: For $n = 1$, since $(u_k)_{k \in K}$ is a Cauchy family, there is some finite subset J_1 of K such that

$$\|u_J\| < 1/2$$

for every finite subset J of K with $J_1 \cap J = \emptyset$. We pick some finite subset J_1 with the above property, and we let $I_1 = J_1$ and

$$X_1 = \{u_I \mid I_1 \subseteq I \subseteq K, I \text{ finite}\}.$$

For $n \geq 1$, there is some finite subset J_{n+1} of K such that

$$\|u_J\| < 1/(2n+2)$$

for every finite subset J of K with $J_{n+1} \cap J = \emptyset$. We pick some finite subset J_{n+1} with the above property, and we let $I_{n+1} = I_n \cup J_{n+1}$ and

$$X_{n+1} = \{u_I \mid I_{n+1} \subseteq I \subseteq K, I \text{ finite}\}.$$

Since $I_n \subseteq I_{n+1}$, it is obvious that $X_{n+1} \subseteq X_n$ for all $n \geq 1$. We need to prove that each X_n has diameter at most $1/n$. Since J_n was chosen such that

$$\|u_J\| < 1/(2n)$$

for every finite subset J of K with $J_n \cap J = \emptyset$, and since $J_n \subseteq I_n$, it is also true that

$$\|u_J\| < 1/(2n)$$

for every finite subset J of K with $I_n \cap J = \emptyset$ (since $I_n \cap J = \emptyset$ and $J_n \subseteq I_n$ implies that $J_n \cap J = \emptyset$). Then for every two finite subsets J, L such that $I_n \subseteq J, L \subseteq K$, we have

$$\|u_{J-I_n}\| < 1/(2n) \quad \text{and} \quad \|u_{L-I_n}\| < 1/(2n),$$

and since

$$\|u_J - u_L\| \leq \|u_J - u_{I_n}\| + \|u_{I_n} - u_L\| = \|u_{J-I_n}\| + \|u_{L-I_n}\|,$$

we get

$$\|u_J - u_L\| < 1/n,$$

which proves that $\delta(X_n) \leq 1/n$. Now if we consider the sequence of closed sets $(\overline{X_n})$, we still have $\overline{X_{n+1}} \subseteq \overline{X_n}$, and by Proposition 48.4, $\delta(\overline{X_n}) = \delta(X_n) \leq 1/n$, which means that $\lim_{n \rightarrow \infty} \delta(\overline{X_n}) = 0$, and by Proposition 48.4, $\bigcap_{n=1}^{\infty} \overline{X_n}$ consists of a single element u . We claim that u is the sum of the family $(u_k)_{k \in K}$.

For every $\epsilon > 0$, there is some $n \geq 1$ such that $n > 2/\epsilon$, and since $u \in \overline{X_m}$ for all $m \geq 1$, there is some finite subset J_0 of K such that $I_n \subseteq J_0$ and

$$\|u - u_{J_0}\| < \epsilon/2,$$

where I_n is the finite subset of K involved in the definition of X_n . However, since $\delta(X_n) \leq 1/n$, for every finite subset J of K such that $I_n \subseteq J$, we have

$$\|u_J - u_{J_0}\| \leq 1/n < \epsilon/2,$$

and since

$$\|u - u_J\| \leq \|u - u_{J_0}\| + \|u_{J_0} - u_J\|,$$

we get

$$\|u - u_J\| < \epsilon$$

for every finite subset J of K with $I_n \subseteq J$, which proves that u is the sum of the family $(u_k)_{k \in K}$.

(2) Since every finite sum $\sum_{i \in I} r_i$ is bounded by the uniform bound B , the set of these finite sums has a least upper bound $r \leq B$. For every $\epsilon > 0$, since r is the least upper bound of the finite sums $\sum_{i \in I} r_i$ (where I finite, $I \subseteq K$), there is some finite $I \subseteq K$ such that

$$\left| r - \sum_{i \in I} r_i \right| < \epsilon,$$

and since $r_k \geq 0$ for all $k \in K$, we have

$$\sum_{i \in I} r_i \leq \sum_{j \in J} r_j$$

whenever $I \subseteq J$, which shows that

$$\left| r - \sum_{j \in J} r_j \right| \leq \left| r - \sum_{i \in I} r_i \right| < \epsilon$$

for every finite subset J such that $I \subseteq J \subseteq K$, proving that $(r_k)_{k \in K}$ is summable with sum $\sum_{k \in K} r_k = r$. \square

Remark: The notion of summability implies that the sum of a family $(u_k)_{k \in K}$ is independent of any order on K . In this sense it is a kind of “commutative summability.” More precisely, it is easy to show that for every bijection $\varphi: K \rightarrow K$ (intuitively, a reordering of K), the family $(u_k)_{k \in K}$ is summable iff the family $(u_l)_{l \in \varphi(K)}$ is summable, and if so, they have the same sum.

The following proposition gives some of the main properties of Fourier coefficients. Among other things, at most countably many of the Fourier coefficient may be nonnull, and the partial sums of a Fourier series converge. Given an orthogonal family $(u_k)_{k \in K}$, we let $U_k = \text{Cu}_k$, and $p_{U_k}: E \rightarrow U_k$ is the projection of E onto U_k .

Proposition A.2. *Let E be a Hilbert space, $(u_k)_{k \in K}$ an orthogonal family in E , and V the closure of the subspace generated by $(u_k)_{k \in K}$. The following properties hold:*

(1) *For every $v \in E$, for every finite subset $I \subseteq K$, we have*

$$\sum_{i \in I} |c_i|^2 \leq \|v\|^2,$$

where the c_k are the Fourier coefficients of v .

(2) *For every vector $v \in E$, if $(c_k)_{k \in K}$ are the Fourier coefficients of v , the following conditions are equivalent:*

(2a) $v \in V$

(2b) *The family $(c_k u_k)_{k \in K}$ is summable and $v = \sum_{k \in K} c_k u_k$.*

(2c) *The family $(|c_k|^2)_{k \in K}$ is summable and $\|v\|^2 = \sum_{k \in K} |c_k|^2$;*

(3) *The family $(|c_k|^2)_{k \in K}$ is summable, and we have the Bessel inequality:*

$$\sum_{k \in K} |c_k|^2 \leq \|v\|^2.$$

As a consequence, at most countably many of the c_k may be nonzero. The family $(c_k u_k)_{k \in K}$ forms a Cauchy family, and thus, the Fourier series $\sum_{k \in K} c_k u_k$ converges in E to some vector $u = \sum_{k \in K} c_k u_k$. Furthermore, $u = p_V(v)$.

See Figure A.1.

Proof. (1) Let

$$u_I = \sum_{i \in I} c_i u_i$$

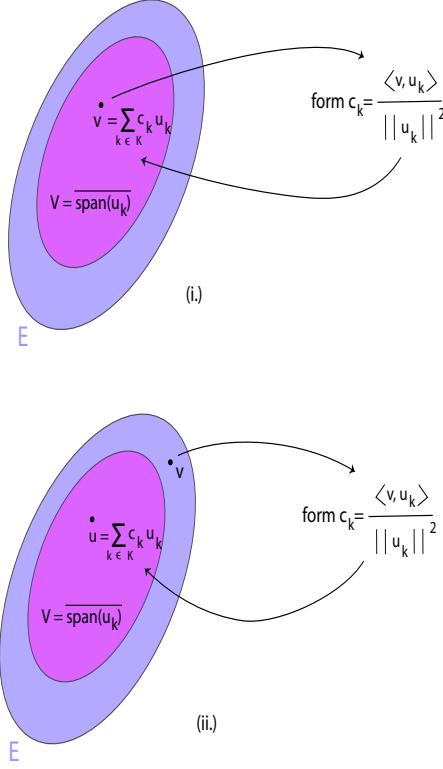

Figure A.1: A schematic illustration of Proposition A.2. Figure (i.) illustrates Condition (2b), while Figure (ii.) illustrates Condition (3). Note E is the purple oval and V is the magenta oval. In both cases, take a vector of E , form the Fourier coefficients c_k , then form the Fourier series $\sum_{k \in K} c_k u_k$. Condition (2b) ensures v equals its Fourier series since $v \in V$. However, if $v \notin V$, the Fourier series does not equal v . Eventually, we will discover that $V = E$, which implies that that Fourier series converges to its vector v .

for any finite subset I of K . We claim that $v - u_I$ is orthogonal to u_i for every $i \in I$. Indeed,

$$\begin{aligned}
\langle v - u_I, u_i \rangle &= \left\langle v - \sum_{j \in I} c_j u_j, u_i \right\rangle \\
&= \langle v, u_i \rangle - \sum_{j \in I} c_j \langle u_j, u_i \rangle \\
&= \langle v, u_i \rangle - c_i \|u_i\|^2 \\
&= \langle v, u_i \rangle - \langle v, u_i \rangle = 0,
\end{aligned}$$

since $\langle u_j, u_i \rangle = 0$ for all $i \neq j$ and $c_i = \langle v, u_i \rangle / \|u_i\|^2$. As a consequence, we have

$$\begin{aligned}\|v\|^2 &= \left\| v - \sum_{i \in I} c_i u_i + \sum_{i \in I} c_i u_i \right\|^2 \\ &= \left\| v - \sum_{i \in I} c_i u_i \right\|^2 + \left\| \sum_{i \in I} c_i u_i \right\|^2 \\ &= \left\| v - \sum_{i \in I} c_i u_i \right\|^2 + \sum_{i \in I} |c_i|^2,\end{aligned}$$

since the u_i are pairwise orthogonal, that is,

$$\|v\|^2 = \left\| v - \sum_{i \in I} c_i u_i \right\|^2 + \sum_{i \in I} |c_i|^2.$$

Thus,

$$\sum_{i \in I} |c_i|^2 \leq \|v\|^2,$$

as claimed.

(2) We prove the chain of implications $(a) \Rightarrow (b) \Rightarrow (c) \Rightarrow (a)$.

$(a) \Rightarrow (b)$: If $v \in V$, since V is the closure of the subspace spanned by $(u_k)_{k \in K}$, for every $\epsilon > 0$, there is some finite subset I of K and some family $(\lambda_i)_{i \in I}$ of complex numbers, such that

$$\left\| v - \sum_{i \in I} \lambda_i u_i \right\| < \epsilon.$$

Now for every finite subset J of K such that $I \subseteq J$, we have

$$\begin{aligned}\left\| v - \sum_{i \in I} \lambda_i u_i \right\|^2 &= \left\| v - \sum_{j \in J} c_j u_j + \sum_{j \in J} c_j u_j - \sum_{i \in I} \lambda_i u_i \right\|^2 \\ &= \left\| v - \sum_{j \in J} c_j u_j \right\|^2 + \left\| \sum_{j \in J} c_j u_j - \sum_{i \in I} \lambda_i u_i \right\|^2,\end{aligned}$$

since $I \subseteq J$ and the u_j (with $j \in J$) are orthogonal to $v - \sum_{j \in J} c_j u_j$ by the argument in (1), which shows that

$$\left\| v - \sum_{j \in J} c_j u_j \right\| \leq \left\| v - \sum_{i \in I} \lambda_i u_i \right\| < \epsilon,$$

and thus, that the family $(c_k u_k)_{k \in K}$ is summable with sum v , so that

$$v = \sum_{k \in K} c_k u_k.$$

(b) \Rightarrow (c): If $v = \sum_{k \in K} c_k u_k$, then for every $\epsilon > 0$, there some finite subset I of K , such that

$$\left\| v - \sum_{j \in J} c_j u_j \right\| < \sqrt{\epsilon},$$

for every finite subset J of K such that $I \subseteq J$, and since we proved in (1) that

$$\|v\|^2 = \left\| v - \sum_{j \in J} c_j u_j \right\|^2 + \sum_{j \in J} |c_j|^2,$$

we get

$$\|v\|^2 - \sum_{j \in J} |c_j|^2 < \epsilon,$$

which proves that $(|c_k|^2)_{k \in K}$ is summable with sum $\|v\|^2$.

(c) \Rightarrow (a): Finally, if $(|c_k|^2)_{k \in K}$ is summable with sum $\|v\|^2$, for every $\epsilon > 0$, there is some finite subset I of K such that

$$\|v\|^2 - \sum_{j \in J} |c_j|^2 < \epsilon^2$$

for every finite subset J of K such that $I \subseteq J$, and again, using the fact that

$$\|v\|^2 = \left\| v - \sum_{j \in J} c_j u_j \right\|^2 + \sum_{j \in J} |c_j|^2,$$

we get

$$\left\| v - \sum_{j \in J} c_j u_j \right\| < \epsilon,$$

which proves that $(c_k u_k)_{k \in K}$ is summable with sum $\sum_{k \in K} c_k u_k = v$, and $v \in V$.

(3) Since $\sum_{i \in I} |c_i|^2 \leq \|v\|^2$ for every finite subset I of K , by Proposition A.1(2), the family $(|c_k|^2)_{k \in K}$ is summable. The Bessel inequality

$$\sum_{k \in K} |c_k|^2 \leq \|v\|^2$$

is an obvious consequence of the inequality $\sum_{i \in I} |c_i|^2 \leq \|v\|^2$ (for every finite $I \subseteq K$). Now for every natural number $n \geq 1$, if K_n is the subset of K consisting of all c_k such that $|c_k| \geq 1/n$, the number of elements in K_n is at most

$$\sum_{k \in K_n} |nc_k|^2 \leq n^2 \sum_{k \in K} |c_k|^2 \leq n^2 \|v\|^2,$$

which is finite, and thus, at most a countable number of the c_k may be nonzero.

Since $(|c_k|^2)_{k \in K}$ is summable with sum c , by Proposition A.1(1) we know that for every $\epsilon > 0$, there is some finite subset I of K such that

$$\sum_{j \in J} |c_j|^2 < \epsilon^2$$

for every finite subset J of K such that $I \cap J = \emptyset$. Since

$$\left\| \sum_{j \in J} c_j u_j \right\|^2 = \sum_{j \in J} |c_j|^2,$$

we get

$$\left\| \sum_{j \in J} c_j u_j \right\| < \epsilon.$$

This proves that $(c_k u_k)_{k \in K}$ is a Cauchy family, which, by Proposition A.1(1), implies that $(c_k u_k)_{k \in K}$ is summable since E is complete. Thus, the Fourier series $\sum_{k \in K} c_k u_k$ is summable, with its sum denoted $u \in V$.

Since $\sum_{k \in K} c_k u_k$ is summable with sum u , for every $\epsilon > 0$, there is some finite subset I_1 of K such that

$$\left\| u - \sum_{j \in J} c_j u_j \right\| < \epsilon$$

for every finite subset J of K such that $I_1 \subseteq J$. By the triangle inequality, for every finite subset I of K ,

$$\left\| u - v \right\| \leq \left\| u - \sum_{i \in I} c_i u_i \right\| + \left\| \sum_{i \in I} c_i u_i - v \right\|.$$

By (2), every $w \in V$ is the sum of its Fourier series $\sum_{k \in K} \lambda_k u_k$, and for every $\epsilon > 0$, there is some finite subset I_2 of K such that

$$\left\| w - \sum_{j \in J} \lambda_j u_j \right\| < \epsilon$$

for every finite subset J of K such that $I_2 \subseteq J$. By the triangle inequality, for every finite subset I of K ,

$$\left\| v - \sum_{i \in I} \lambda_i u_i \right\| \leq \|v - w\| + \left\| w - \sum_{i \in I} \lambda_i u_i \right\|.$$

Letting $I = I_1 \cup I_2$, since we showed in (2) that

$$\left\| v - \sum_{i \in I} c_i u_i \right\| \leq \left\| v - \sum_{i \in I} \lambda_i u_i \right\|$$

for every finite subset I of K , we get

$$\begin{aligned}\|u - v\| &\leq \left\| u - \sum_{i \in I} c_i u_i \right\| + \left\| \sum_{i \in I} c_i u_i - v \right\| \\ &\leq \left\| u - \sum_{i \in I} c_i u_i \right\| + \left\| \sum_{i \in I} \lambda_i u_i - v \right\| \\ &\leq \left\| u - \sum_{i \in I} c_i u_i \right\| + \|v - w\| + \left\| w - \sum_{i \in I} \lambda_i u_i \right\|,\end{aligned}$$

and thus

$$\|u - v\| \leq \|v - w\| + 2\epsilon.$$

Since this holds for every $\epsilon > 0$, we have

$$\|u - v\| \leq \|v - w\|$$

for all $w \in V$, i.e. $\|v - u\| = d(v, V)$, with $u \in V$, which proves that $u = p_V(v)$. \square

A.2 The Hilbert Space $\ell^2(K)$ and the Riesz–Fischer Theorem

Proposition A.2 suggests looking at the space of sequences $(z_k)_{k \in K}$ (where $z_k \in \mathbb{C}$) such that $(|z_k|^2)_{k \in K}$ is summable. Indeed, such spaces are Hilbert spaces, and it turns out that every Hilbert space is isomorphic to one of those. Such spaces are the infinite-dimensional version of the spaces \mathbb{C}^n under the usual Euclidean norm.

Definition A.3. Given any nonempty index set K , the space $\ell^2(K)$ is the set of all sequences $(z_k)_{k \in K}$, where $z_k \in \mathbb{C}$, such that $(|z_k|^2)_{k \in K}$ is summable, i.e., $\sum_{k \in K} |z_k|^2 < \infty$.

Remarks:

- (1) When K is a finite set of cardinality n , $\ell^2(K)$ is isomorphic to \mathbb{C}^n .
- (2) When $K = \mathbb{N}$, the space $\ell^2(\mathbb{N})$ corresponds to the space ℓ^2 of Example 2 in Section 14.1. In that example, we claimed that ℓ^2 was a Hermitian space, and in fact, a Hilbert space. We now prove this fact for any index set K .

Proposition A.3. *Given any nonempty index set K , the space $\ell^2(K)$ is a Hilbert space under the Hermitian product*

$$\langle (x_k)_{k \in K}, (y_k)_{k \in K} \rangle = \sum_{k \in K} x_k \overline{y_k}.$$

The subspace consisting of sequences $(z_k)_{k \in K}$ such that $z_k = 0$, except perhaps for finitely many k , is a dense subspace of $\ell^2(K)$.

Proof. First we need to prove that $\ell^2(K)$ is a vector space. Assume that $(x_k)_{k \in K}$ and $(y_k)_{k \in K}$ are in $\ell^2(K)$. This means that $(|x_k|^2)_{k \in K}$ and $(|y_k|^2)_{k \in K}$ are summable, which, in view of Proposition A.1(2), is equivalent to the existence of some positive bounds A and B such that $\sum_{i \in I} |x_i|^2 < A$ and $\sum_{i \in I} |y_i|^2 < B$, for every finite subset I of K . To prove that $(|x_k + y_k|^2)_{k \in K}$ is summable, it is sufficient to prove that there is some $C > 0$ such that $\sum_{i \in I} |x_i + y_i|^2 < C$ for every finite subset I of K . However, the parallelogram inequality implies that

$$\sum_{i \in I} |x_i + y_i|^2 \leq \sum_{i \in I} 2(|x_i|^2 + |y_i|^2) \leq 2(A + B),$$

for every finite subset I of K , and we conclude by Proposition A.1(2). Similarly, for every $\lambda \in \mathbb{C}$,

$$\sum_{i \in I} |\lambda x_i|^2 \leq \sum_{i \in I} |\lambda|^2 |x_i|^2 \leq |\lambda|^2 A,$$

and $(\lambda_k x_k)_{k \in K}$ is summable. Therefore, $\ell^2(K)$ is a vector space.

By the Cauchy–Schwarz inequality,

$$\sum_{i \in I} |x_i \bar{y}_i| \leq \sum_{i \in I} |x_i| |y_i| \leq \left(\sum_{i \in I} |x_i|^2\right)^{1/2} \left(\sum_{i \in I} |y_i|^2\right)^{1/2} \leq \sum_{i \in I} (|x_i|^2 + |y_i|^2)/2 \leq (A + B)/2,$$

for every finite subset I of K . For the third inequality we used the fact that

$$4CD \leq (C + D)^2,$$

(with $C = \sum_{i \in I} |x_i|^2$ and $D = \sum_{i \in I} |y_i|^2$) which is equivalent to

$$(C - D)^2 \geq 0.$$

By Proposition A.1(2), $(|x_k \bar{y}_k|)_{k \in K}$ is summable. The customary language is that $(x_k \bar{y}_k)_{k \in K}$ is absolutely summable. However, it is a standard fact that this implies that $(x_k \bar{y}_k)_{k \in K}$ is summable (For every $\epsilon > 0$, there is some finite subset I of K such that

$$\sum_{j \in J} |x_j \bar{y}_j| < \epsilon$$

for every finite subset J of K such that $I \cap J = \emptyset$, and thus

$$|\sum_{j \in J} x_j \bar{y}_j| \leq \sum_{i \in J} |x_j \bar{y}_j| < \epsilon,$$

proving that $(x_k \bar{y}_k)_{k \in K}$ is a Cauchy family, and thus summable). We still have to prove that $\ell^2(K)$ is complete.

Consider a sequence $((\lambda_k^n)_{k \in K})_{n \geq 1}$ of sequences $(\lambda_k^n)_{k \in K} \in \ell^2(K)$, and assume that it is a Cauchy sequence. This means that for every $\epsilon > 0$, there is some $N \geq 1$ such that

$$\sum_{k \in K} |\lambda_k^m - \lambda_k^n|^2 < \epsilon^2$$

for all $m, n \geq N$. For every fixed $k \in K$, this implies that

$$|\lambda_k^m - \lambda_k^n| < \epsilon$$

for all $m, n \geq N$, which shows that $(\lambda_k^n)_{n \geq 1}$ is a Cauchy sequence in \mathbb{C} . Since \mathbb{C} is complete, the sequence $(\lambda_k^n)_{n \geq 1}$ has a limit $\lambda_k \in \mathbb{C}$. We claim that $(\lambda_k)_{k \in K} \in \ell^2(K)$ and that this is the limit of $((\lambda_k^n)_{k \in K})_{n \geq 1}$.

Given any $\epsilon > 0$, the fact that $((\lambda_k^n)_{k \in K})_{n \geq 1}$ is a Cauchy sequence implies that there is some $N \geq 1$ such that for every finite subset I of K , we have

$$\sum_{i \in I} |\lambda_i^m - \lambda_i^n|^2 < \epsilon/4$$

for all $m, n \geq N$. Let $p = |I|$. Then

$$|\lambda_i^m - \lambda_i^n| < \frac{\sqrt{\epsilon}}{2\sqrt{p}}$$

for every $i \in I$. Since λ_i is the limit of $(\lambda_i^n)_{n \geq 1}$, we can find some n large enough so that

$$|\lambda_i^n - \lambda_i| < \frac{\sqrt{\epsilon}}{2\sqrt{p}}$$

for every $i \in I$. Since

$$|\lambda_i^m - \lambda_i| \leq |\lambda_i^m - \lambda_i^n| + |\lambda_i^n - \lambda_i|,$$

we get

$$|\lambda_i^m - \lambda_i| < \frac{\sqrt{\epsilon}}{\sqrt{p}},$$

and thus,

$$\sum_{i \in I} |\lambda_i^m - \lambda_i|^2 < \epsilon,$$

for all $m \geq N$. Since the above holds for every finite subset I of K , by Proposition A.1(2), we get

$$\sum_{k \in K} |\lambda_k^m - \lambda_k|^2 < \epsilon,$$

for all $m \geq N$. This proves that $(\lambda_k^m - \lambda_k)_{k \in K} \in \ell^2(K)$ for all $m \geq N$, and since $\ell^2(K)$ is a vector space and $(\lambda_k^m)_{k \in K} \in \ell^2(K)$ for all $m \geq 1$, we get $(\lambda_k)_{k \in K} \in \ell^2(K)$. However,

$$\sum_{k \in K} |\lambda_k^m - \lambda_k|^2 < \epsilon$$

for all $m \geq N$, means that the sequence $(\lambda_k^m)_{k \in K}$ converges to $(\lambda_k)_{k \in K} \in \ell^2(K)$. The fact that the subspace consisting of sequences $(z_k)_{k \in K}$ such that $z_k = 0$ except perhaps for finitely many k is a dense subspace of $\ell^2(K)$ is left as an easy exercise. \square

Remark: The subspace consisting of all sequences $(z_k)_{k \in K}$ such that $z_k = 0$, except perhaps for finitely many k , provides an example of a subspace which is not closed in $\ell^2(K)$. Indeed, this space is strictly contained in $\ell^2(K)$, since there are countable sequences of nonnull elements in $\ell^2(K)$ (why?).

We just need two more propositions before being able to prove that every Hilbert space is isomorphic to some $\ell^2(K)$.

Proposition A.4. *Let E be a Hilbert space, and $(u_k)_{k \in K}$ an orthogonal family in E . The following properties hold:*

- (1) *For every family $(\lambda_k)_{k \in K} \in \ell^2(K)$, the family $(\lambda_k u_k)_{k \in K}$ is summable. Furthermore, $v = \sum_{k \in K} \lambda_k u_k$ is the only vector such that $c_k = \lambda_k$ for all $k \in K$, where the c_k are the Fourier coefficients of v .*
- (2) *For any two families $(\lambda_k)_{k \in K} \in \ell^2(K)$ and $(\mu_k)_{k \in K} \in \ell^2(K)$, if $v = \sum_{k \in K} \lambda_k u_k$ and $w = \sum_{k \in K} \mu_k u_k$, we have the following equation, also called Parseval identity:*

$$\langle v, w \rangle = \sum_{k \in K} \lambda_k \overline{\mu_k}.$$

Proof. (1) The fact that $(\lambda_k)_{k \in K} \in \ell^2(K)$ means that $(|\lambda_k|^2)_{k \in K}$ is summable. The proof given in Proposition A.2 (3) applies to the family $(|\lambda_k|^2)_{k \in K}$ (instead of $(|c_k|^2)_{k \in K}$), and yields the fact that $(\lambda_k u_k)_{k \in K}$ is summable. Letting $v = \sum_{k \in K} \lambda_k u_k$, recall that $c_k = \langle v, u_k \rangle / \|u_k\|^2$. Pick some $k \in K$. Since $\langle -, - \rangle$ is continuous, for every $\epsilon > 0$, there is some $\eta > 0$ such that

$$|\langle v, u_k \rangle - \langle w, u_k \rangle| < \epsilon \|u_k\|^2$$

whenever

$$\|v - w\| < \eta.$$

However, since for every $\eta > 0$, there is some finite subset I of K such that

$$\left\| v - \sum_{j \in J} \lambda_j u_j \right\| < \eta$$

for every finite subset J of K such that $I \subseteq J$, we can pick $J = I \cup \{k\}$ and letting $w = \sum_{j \in J} \lambda_j u_j$ we get

$$\left| \langle v, u_k \rangle - \left\langle \sum_{j \in J} \lambda_j u_j, u_k \right\rangle \right| < \epsilon \|u_k\|^2.$$

However,

$$\langle v, u_k \rangle = c_k \|u_k\|^2 \quad \text{and} \quad \left\langle \sum_{j \in J} \lambda_j u_j, u_k \right\rangle = \lambda_k \|u_k\|^2,$$

and thus, the above proves that $|c_k - \lambda_k| < \epsilon$ for every $\epsilon > 0$, and thus, that $c_k = \lambda_k$.

(2) Since $\langle -, - \rangle$ is continuous, for every $\epsilon > 0$, there are some $\eta_1 > 0$ and $\eta_2 > 0$, such that

$$|\langle x, y \rangle| < \epsilon$$

whenever $\|x\| < \eta_1$ and $\|y\| < \eta_2$. Since $v = \sum_{k \in K} \lambda_k u_k$ and $w = \sum_{k \in K} \mu_k u_k$, there is some finite subset I_1 of K such that

$$\left\| v - \sum_{j \in J} \lambda_j u_j \right\| < \eta_1$$

for every finite subset J of K such that $I_1 \subseteq J$, and there is some finite subset I_2 of K such that

$$\left\| w - \sum_{j \in J} \mu_j u_j \right\| < \eta_2$$

for every finite subset J of K such that $I_2 \subseteq J$. Letting $I = I_1 \cup I_2$, we get

$$\left| \left\langle v - \sum_{i \in I} \lambda_i u_i, w - \sum_{i \in I} \mu_i u_i \right\rangle \right| < \epsilon.$$

Furthermore,

$$\begin{aligned} \langle v, w \rangle &= \left\langle v - \sum_{i \in I} \lambda_i u_i + \sum_{i \in I} \lambda_i u_i, w - \sum_{i \in I} \mu_i u_i + \sum_{i \in I} \mu_i u_i \right\rangle \\ &= \left\langle v - \sum_{i \in I} \lambda_i u_i, w - \sum_{i \in I} \mu_i u_i \right\rangle + \sum_{i \in I} \lambda_i \overline{\mu_i}, \end{aligned}$$

since the u_i are orthogonal to $v - \sum_{i \in I} \lambda_i u_i$ and $w - \sum_{i \in I} \mu_i u_i$ for all $i \in I$. This proves that for every $\epsilon > 0$, there is some finite subset I of K such that

$$\left| \langle v, w \rangle - \sum_{i \in I} \lambda_i \overline{\mu_i} \right| < \epsilon.$$

We already know from Proposition A.3 that $(\lambda_k \overline{\mu_k})_{k \in K}$ is summable, and since $\epsilon > 0$ is arbitrary we get

$$\langle v, w \rangle = \sum_{k \in K} \lambda_k \overline{\mu_k}.$$

□

The next proposition states properties characterizing Hilbert bases (total orthogonal families).

Proposition A.5. *Let E be a Hilbert space, and let $(u_k)_{k \in K}$ be an orthogonal family in E . The following properties are equivalent:*

- (1) The family $(u_k)_{k \in K}$ is a total orthogonal family.
- (2) For every vector $v \in E$, if $(c_k)_{k \in K}$ are the Fourier coefficients of v , then the family $(c_k u_k)_{k \in K}$ is summable and $v = \sum_{k \in K} c_k u_k$.
- (3) For every vector $v \in E$, we have the Parseval identity:

$$\|v\|^2 = \sum_{k \in K} |c_k|^2.$$

- (4) For every vector $u \in E$, if $\langle u, u_k \rangle = 0$ for all $k \in K$, then $u = 0$.

See Figure A.2.

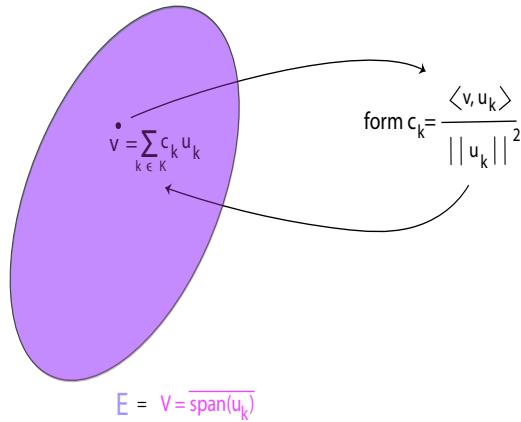

Figure A.2: A schematic illustration of Proposition A.5. Since $(u_k)_{k \in K}$ is a Hilbert basis, $V = E$. Then given a vector of E , if we form the Fourier coefficients c_k , then form the Fourier series $\sum_{k \in K} c_k u_k$, we are ensured that v is equal to its Fourier series.

Proof. The equivalence of (1), (2), and (3) is an immediate consequence of Proposition A.2 and Proposition A.4.

(4) If $(u_k)_{k \in K}$ is a total orthogonal family and $\langle u, u_k \rangle = 0$ for all $k \in K$, since $u = \sum_{k \in K} c_k u_k$ where $c_k = \langle u, u_k \rangle / \|u_k\|^2$, we have $c_k = 0$ for all $k \in K$, and $u = 0$.

Conversely, assume that the closure V of $(u_k)_{k \in K}$ is different from E . Then by Proposition 48.7, we have $E = V \oplus V^\perp$, where V^\perp is the orthogonal complement of V , and V^\perp is nontrivial since $V \neq E$. As a consequence, there is some nonnull vector $u \in V^\perp$. But then u is orthogonal to every vector in V , and in particular,

$$\langle u, u_k \rangle = 0$$

for all $k \in K$, which, by assumption, implies that $u = 0$, contradicting the fact that $u \neq 0$. \square

Remarks:

- (1) If E is a Hilbert space and $(u_k)_{k \in K}$ is a total orthogonal family in E , there is a simpler argument to prove that $u = 0$ if $\langle u, u_k \rangle = 0$ for all $k \in K$ based on the continuity of $\langle -, - \rangle$. The argument is to prove that the assumption implies that $\langle v, u \rangle = 0$ for all $v \in E$. Since $\langle -, - \rangle$ is positive definite, this implies that $u = 0$. By continuity of $\langle -, - \rangle$, for every $\epsilon > 0$, there is some $\eta > 0$ such that for every finite subset I of K , for every family $(\lambda_i)_{i \in I}$, for every $v \in E$,

$$\left| \langle v, u \rangle - \left\langle \sum_{i \in I} \lambda_i u_i, u \right\rangle \right| < \epsilon$$

whenever

$$\left\| v - \sum_{i \in I} \lambda_i u_i \right\| < \eta.$$

Since $(u_k)_{k \in K}$ is dense in E , for every $v \in E$, there is some finite subset I of K and some family $(\lambda_i)_{i \in I}$ such that

$$\left\| v - \sum_{i \in I} \lambda_i u_i \right\| < \eta,$$

and since by assumption, $\langle \sum_{i \in I} \lambda_i u_i, u \rangle = 0$, we get

$$|\langle v, u \rangle| < \epsilon.$$

Since this holds for every $\epsilon > 0$, we must have $\langle v, u \rangle = 0$

- (2) If V is any nonempty subset of E , the kind of argument used in the previous remark can be used to prove that V^\perp is closed (even if V is not), and that $V^{\perp\perp}$ is the closure of V .

We will now prove that **every Hilbert space has some Hilbert basis**. This requires using a fundamental theorem from set theory known as *Zorn's lemma*, which we quickly review.

Given any set X with a partial ordering \leq , recall that a nonempty subset C of X is a *chain* if it is totally ordered (i.e., for all $x, y \in C$, either $x \leq y$ or $y \leq x$). A nonempty subset Y of X is *bounded* iff there is some $b \in X$ such that $y \leq b$ for all $y \in Y$. Some $m \in X$ is *maximal* iff for every $x \in X$, $m \leq x$ implies that $x = m$. We can now state Zorn's lemma. For more details, see Rudin [140], Lang [109], or Artin [7].

Proposition A.6. (Zorn's lemma) *Given any nonempty partially ordered set X , if every (nonempty) chain in X is bounded, then X has some maximal element.*

We can now prove the existence of Hilbert bases. We define a partial order on families $(u_k)_{k \in K}$ as follows: for any two families $(u_k)_{k \in K_1}$ and $(v_k)_{k \in K_2}$, we say that

$$(u_k)_{k \in K_1} \leq (v_k)_{k \in K_2}$$

iff $K_1 \subseteq K_2$ and $u_k = v_k$ for all $k \in K_1$. This is clearly a partial order.

Proposition A.7. *Let E be a Hilbert space. Given any orthogonal family $(u_k)_{k \in K}$ in E , there is a total orthogonal family $(u_l)_{l \in L}$ containing $(u_k)_{k \in K}$.*

Proof. Consider the set \mathcal{S} of all orthogonal families greater than or equal to the family $B = (u_k)_{k \in K}$. We claim that every chain in \mathcal{S} is bounded. Indeed, if $C = (C_l)_{l \in L}$ is a chain in \mathcal{S} , where $C_l = (u_{k,l})_{k \in K_l}$, the union family

$$(u_k)_{k \in \bigcup_{l \in L} K_l}, \text{ where } u_k = u_{k,l} \text{ whenever } k \in K_l,$$

is clearly an upper bound for C , and it is immediately verified that it is an orthogonal family. By Zorn's Lemma A.6, there is a maximal family $(u_l)_{l \in L}$ containing $(u_k)_{k \in K}$. If $(u_l)_{l \in L}$ is not dense in E , then its closure V is strictly contained in E , and by Proposition 48.7, the orthogonal complement V^\perp of V is nontrivial since $V \neq E$. As a consequence, there is some nonnull vector $u \in V^\perp$. But then u is orthogonal to every vector in $(u_l)_{l \in L}$, and we can form an orthogonal family strictly greater than $(u_l)_{l \in L}$ by adding u to this family, contradicting the maximality of $(u_l)_{l \in L}$. Therefore, $(u_l)_{l \in L}$ is dense in E , and thus it is a Hilbert basis. \square

Remark: It is possible to prove that all Hilbert bases for a Hilbert space E have index sets K of the same cardinality. For a proof, see Bourbaki [27].

Definition A.4. A Hilbert space E is *separable* if its Hilbert bases are countable.

At last, we can prove that every Hilbert space is isomorphic to some Hilbert space $\ell^2(K)$ for some suitable K .

Theorem A.8. (Riesz–Fischer) *For every Hilbert space E , there is some nonempty set K such that E is isomorphic to the Hilbert space $\ell^2(K)$. More specifically, for any Hilbert basis $(u_k)_{k \in K}$ of E , the maps $f: \ell^2(K) \rightarrow E$ and $g: E \rightarrow \ell^2(K)$ defined such that*

$$f((\lambda_k)_{k \in K}) = \sum_{k \in K} \lambda_k u_k \quad \text{and} \quad g(u) = (\langle u, u_k \rangle / \|u_k\|^2)_{k \in K} = (c_k)_{k \in K},$$

are bijective linear isometries such that $g \circ f = \text{id}$ and $f \circ g = \text{id}$.

Proof. By Proposition A.4 (1), the map f is well defined, and it is clearly linear. By Proposition A.2 (3), the map g is well defined, and it is also clearly linear. By Proposition A.2 (2b), we have

$$f(g(u)) = u = \sum_{k \in K} c_k u_k,$$

and by Proposition A.4 (1), we have

$$g(f((\lambda_k)_{k \in K})) = (\lambda_k)_{k \in K},$$

and thus $g \circ f = \text{id}$ and $f \circ g = \text{id}$. By Proposition A.4 (2), the linear map g is an isometry. Therefore, f is a linear bijection and an isometry between $\ell^2(K)$ and E , with inverse g . \square

Remark: The surjectivity of the map $g: E \rightarrow \ell^2(K)$ is known as the *Riesz–Fischer theorem*.

Having done all this hard work, we sketch how these results apply to Fourier series. Again we refer the readers to Rudin [140] or Lang [111, 112] for a comprehensive exposition.

Let $\mathcal{C}(T)$ denote the set of all periodic continuous functions $f: [-\pi, \pi] \rightarrow \mathbb{C}$ with period 2π . There is a Hilbert space $L^2(T)$ containing $\mathcal{C}(T)$ and such that $\mathcal{C}(T)$ is dense in $L^2(T)$, whose inner product is given by

$$\langle f, g \rangle = \int_{-\pi}^{\pi} f(x) \overline{g(x)} dx.$$

The Hilbert space $L^2(T)$ is the space of *Lebesgue square-integrable periodic functions* (of period 2π).

It turns out that the family $(e^{ikx})_{k \in \mathbb{Z}}$ is a total orthogonal family in $L^2(T)$, because it is already dense in $\mathcal{C}(T)$ (for instance, see Rudin [140]). Then the Riesz–Fischer theorem says that for every family $(c_k)_{k \in \mathbb{Z}}$ of complex numbers such that

$$\sum_{k \in \mathbb{Z}} |c_k|^2 < \infty,$$

there is a unique function $f \in L^2(T)$ such that f is equal to its Fourier series

$$f(x) = \sum_{k \in \mathbb{Z}} c_k e^{ikx},$$

where the Fourier coefficients c_k of f are given by the formula

$$c_k = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(t) e^{-ikt} dt.$$

The Parseval theorem says that

$$\sum_{k=-\infty}^{+\infty} c_k \overline{d_k} = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(t) \overline{g(t)} dt$$

for all $f, g \in L^2(T)$, where c_k and d_k are the Fourier coefficients of f and g .

Thus, there is an isomorphism between the two Hilbert spaces $L^2(T)$ and $\ell^2(\mathbb{Z})$, which is the deep reason why the Fourier coefficients “work.” Theorem A.8 implies that the Fourier series $\sum_{k \in \mathbb{Z}} c_k e^{ikx}$ of a function $f \in L^2(T)$ converges to f in the L^2 -sense, i.e., in the mean-square sense. This does not necessarily imply that the Fourier series converges to f pointwise! This is a subtle issue, and for more on this subject, the reader is referred to Lang [111, 112] or Schwartz [152, 153].

We can also consider the set $\mathcal{C}([-1, 1])$ of continuous functions $f: [-1, 1] \rightarrow \mathbb{C}$. There is a Hilbert space $L^2([-1, 1])$ containing $\mathcal{C}([-1, 1])$ and such that $\mathcal{C}([-1, 1])$ is dense in $L^2([-1, 1])$, whose inner product is given by

$$\langle f, g \rangle = \int_{-1}^1 f(x) \overline{g(x)} dx.$$

The Hilbert space $L^2([-1, 1])$ is the space of *Lebesgue square-integrable functions* over $[-1, 1]$. The Legendre polynomials $P_n(x)$ defined in Example 5 of Section 12.2 (Chapter 12). form a Hilbert basis of $L^2([-1, 1])$. Recall that if we let f_n be the function

$$f_n(x) = (x^2 - 1)^n,$$

$P_n(x)$ is defined as follows:

$$P_0(x) = 1, \quad \text{and} \quad P_n(x) = \frac{1}{2^n n!} f_n^{(n)}(x),$$

where $f_n^{(n)}$ is the n th derivative of f_n . The reason for the leading coefficient is to get $P_n(1) = 1$. It can be shown with much efforts that

$$P_n(x) = \sum_{0 \leq k \leq n/2} (-1)^k \frac{(2(n-k))!}{2^n (n-k)! k! (n-2k)!} x^{n-2k}.$$

A.3 Summary

The main concepts and results of this chapter are listed below:

- Hilbert space
- Orthogonal family, total orthogonal family.
- Hilbert basis.
- Fourier coefficients.
- Hamel bases, Schauder bases.
- Fourier series.

- Cauchy family, summable family.
- Bessel inequality.
- The Hilbert space $\ell^2(K)$.
- Parseval identity.
- Zorn's lemma.
- Riesz–Fischer theorem.
- Legendre polynomials.

A.4 Problems

Problem A.1. Prove that the subspace consisting of sequences $(z_k)_{k \in K}$ such that $z_k = 0$ except perhaps for finitely many k is a dense suspace of $\ell^2(K)$.

Problem A.2. If V is any nonempty subset of E , prove that V^\perp is closed (even if V is not) and that $V^{\perp\perp}$ is the closure of V (see the remarks following Proposition A.5).

Appendix B

Matlab Programs

B.1 Hard Margin (SVM_{h2})

The following Matlab programs implement the method described in Section 5.2.7.

The first program is the heart of the method; it implements ADMM for quadratic programming.

```
function [x,u,nr,ns,k] = qsolve1(P, q, A, b, rho, tol, tols, iternum)
% Solve a quadratic programming problem
% min (1/2) x^T P x + x^T q + r
% subject to Ax = b, x >= 0 using ADMM
% P n x n, q, r, in R^n, A m x n, b in R^m
% A of rank m

m = size(A,1); fprintf('m = %d ',m)
n = size(P,1); fprintf('    n = %d \n',n)
u = ones(n,1); u(1,1) = 0; % to initialize u
z = ones(n,1); % to initialize z
% iternum = maximum number of iterations;
% iternum = 80000 works well
k = 0; nr= 1; ns = 1;
% typically tol = 10^(-10); tols = 10^(-10);
% Convergence is controlled by the norm nr of the primal residual r
% and the norm ns of the dual residual s

while (k <= iternum) && (ns > tols || nr > tol)
    z0 = z;
    k = k+1;
    % Makes KKT matrix
    KK = [P + rho* eye(n) A'; A zeros(m,m)];
```

```
% Makes right hand side of KKT equation
bb = [-q + rho*(z - u); b];
% Solves KKT equation
xx = KK\bb;
% update x, z, u (ADMM update steps)
x = xx(1:n);
z = poslin(x + u);
u = u + x - z;
% to test stopping criterion
r = x - z; % primal residual
nr = sqrt(r'*r); % norm of primal residual
s = rho*(z - z0); % dual residual
ns = sqrt(s'*s); % norm of dual residual
end
end
```

The second program SBVMhard2 implements hard margin SVM (version 2).

```
function [lamb,mu,w] = SVMhard2(rho,u,v)
%
% Runs hard margin SVM version 2
%
% p green vectors u_1, ..., u_p in n x p array u
% q red   vectors v_1, ..., v_q in n x q array v
%
% First builds the matrices for the dual program
%
p = size(u,2); q = size(v,2); n = size(u,1);
[A,c,X,Pa,qa] = buildhardSVM2(u,v);
%
% Runs quadratic solver
%
tolr = 10^(-10); tols = 10^(-10); iternum = 80000;
[lam,U,nr,ns,kk] = qsolve1(Pa, qa, A, c, rho, tolr, tols, iternum);
fprintf('nr = %d ',nr)
fprintf(' ns = %d \n',ns)
fprintf('kk = %d \n',kk)
if kk > iternum
    fprintf('** qsolve did not converge. Problem not solvable ** \n')
end
w = -X*lam;
nw = sqrt(w'*w); % norm of w
fprintf('nw = %.15f \n',nw)
```

```

delta = 1/nw;
fprintf('delta = %.15f \n',delta)
if delta < 10^(-9)
    fprintf('** Warning, delta too small, program does not converge ** \n')
end
%
lamb = lam(1:p,1);
mu = lam(p+1:p+q,1);
b = 0;
tol = 10^(-10);
% tol < lambda_i; finds the nonzero lambda_i
[lambnz,numsvl1] = countmlu2(lamb,tol);
% tol < mu_i; finds the nonzero mu_j
[unz,numsvm1] = countmlv2(mu,tol);
fprintf('numsvl1 = %d ',numsvl1)
fprintf(' numsvm1 = %d \n',numsvm1)

if numsvl1 > 0 && numsvm1 > 0
    sx1 = zeros(n,1);  num1 = 0;
    sx2 = zeros(n,1);  num2 = 0;
    for i = 1:p
        if lambnz(i) > 0
            sx1 = sx1 + u(:,i);
            num1 = num1 + 1;
        end
    end
    for j = 1:q
        if unz(j) > 0
            sx2 = sx2 + v(:,j);
            num2 = num2 + 1;
        end
    end
    b = (w'*(sx1/num1 + sx2/num2))/2;
    fprintf('b = %.15f \n',b)
else
    fprintf('** Not enough support vectors ** \n')
end

if n == 2
    [ll,mm] = showdata(u,v);
    if numsvl1 > 0 && numsvm1 > 0
        showSVMs2(w,b,1,ll,mm,nw)
    end
end

```

```

    end
end
end

```

The function `buildhardSVM2` builds the constraint matrix and the matrices defining the quadratic functional.

```

function [A,c,X,Xa,q] = buildhardSVM2(u,v)
%   builds the matrix of constraints A for
%   hard SVM h2, and the right hand side c
%   Also builds X and Xa = X'*X, and the vector q = -1_{p+q}
%   for the linear part of the quadratic function
%   The right-hand side is c = 0 (Ax = 0).
p = size(u,2); q = size(v,2);
A = [ones(1,p) -ones(1,q)];
c = 0;
X = [-u v];
Xa = X'*X;
q = -ones(p+q,1);
end

```

The function `countmlu2` returns a vector consisting of those λ_i such that $\lambda_i > 0$, and the number of such λ_i .

```

function [lambnz, mlu] = countmlu2(lambda,tols)
% Counts the number of points u_i (in u)
% such that lambda_i > 0 and returns a vector
% of these lambda_i

% tols = 10^(-11);
p = size(lambda,1); lambnz = zeros(p,1);
mlu = 0;
for i = 1:p
    if lambda(i) > tols
        mlu = mlu + 1;
        lambnz(i) = lambda(i);
    end
end
end

```

The function `countmlv2` returns a vector consisting of those μ_j such that $\mu_j > 0$, and the number of such μ_j . It is similar to `countmlu2`. Here a judicious choice of `tols` is crucial and one has to experiment with various values.

The function `showdata` displays the data points (the u_i and the v_j) and the function `showSVMs2` displays the separating line and the two margin lines.

```
function showSVMs2(w,b,eta,ll,mm,nw)
%
% Function to display the result of running SVM
% on p blue points u_1, ..., u_p in u
% and q red points v_1, ..., v_q in v

l = makeline(w,b,ll,mm,nw);           % makes separating line
lm1 = makeline(w,b+eta,ll,mm,nw);     % makes blue margin line
lm2 = makeline(w,b-eta,ll,mm,nw);     % makes red margin line

plot(l(1,:),l(2,:),'-m','LineWidth',1.2)          % plots separating line
plot(lm1(1,:),lm1(2,:),'-b','LineWidth',1.2)      % plots blue margin line
plot(lm2(1,:),lm2(2,:),'-r','LineWidth',1.2)      % plots red margin line
hold off
end
```

Actually, implementing the above function is not entirely trivial. It is necessary to write a function `makeline` to plot the line segment which is part of the line of equation $w_1x + w_2y = b$ inside a box containing the data points. We leave the details an exercises.

B.2 Soft Margin SVM ($\text{SVM}_{s2'}$)

The following Matlab programs implement the method described in Section 54.8.

The function `doSVMs2pbv3` calls the function `solve1` given in Section 52.7.

```
function [lamb,mu,alpha,beta,lambnz,munz,numsvl1,numsvm1,badnu,w,nw,b,eta]
    = doSVMs2pbv3(nu,rho,u,v,K)
%
% Best version
% Uses the duality gap to compute eta
% In principle, needs a single support vector of type 1
%
% Soft margin nu-SVM version s2'
% with the constraint
% \sum_{i = 1}^p + \sum_{j = 1}^q mu_j = K_m
% (without the variable gamma)
%
% p green vectors u_1, ..., u_p in n x p array u
% q red   vectors v_1, ..., v_q in n x q array v
```

```

%
% First builds the matrices for the dual program
% K is a scale factor
%
p = size(u,2); q = size(v,2); n = size(u,1);
[A,c,X,Pa,qa] = buildSVMs2pb(nu,u,v,K);
%
% Runs quadratic solver
%
tolr = 10^(-10); tols = 10^(-10); iternum = 80000;
[x,U,nr,ns,kk] = qsolve1(Pa, qa, A, c, rho, tolr, tols, iternum);
fprintf('nr = %d ',nr)
fprintf(' ns = %d \n',ns)
fprintf('kk = %d \n',kk)
noconv = 0;
if kk > iternum
    noconv = 1;
    fprintf('** qsolve did not converge. Problem not solvable ** \n')
end
lam = x(1:(p+q),1);
alpha = x((p+q+1):2*p+q,1);
beta = x(2*p+q+1:2*(p+q),1);
w = -X*lam;
nw = sqrt(w'*w);    % norm of w
fprintf('nw = %d \n',nw)
%
lamb = x(1:p,1);
mu = x(p+1:p+q,1);
tolz = 10^(-10); tolh = 10^(-9);
% tolz < lambda_i < K - tolh
[lambnz,numsvl1] = findpsv2(lamb,K,tolz,tolh);
% tolz < mu_i < K - tolh
[munz,numsvm1] = findpsv2(mu,K,tolz,tolh);
fprintf('numsvl1 = %d ',numsvl1)
fprintf(' numsvm1 = %d \n',numsvm1)
% lambda_i >= K - tolh
[lamK,pf] = countumf2(lamb,K,tolh); % number of blue margin failures
% mu_j >= K - tolh
[muK,qf] = countvmf2(mu,K,tolh); % number of red margin failures
fprintf('pf = %d ',pf)
fprintf(' qf = %d \n',qf)
[~,pm] = countmlu2(lamb,tolz); % number of points such that lambda_i > tolz

```

```
[~,qm] = countmlv2(mu,tols); % number of points such that mu_i > 0
fprintf('pm = %d ',pm)
fprintf(' qm = %d \n',qm)
fprintf('p - pm = %d ',p - pm)
fprintf(' q - qm = %d \n',q - qm)
lnu = max(2*pf/(p+q),2*qf/(p+q)); unu = min(2*pm/(p+q),2*qm/(p+q));
fprintf('lnu = %d ',lnu)
fprintf(' unu = %d \n',unu)
if nu < lnu
    fprintf('** Warning; nu is too small ** \n')
else
    if nu > unu
        fprintf('** Warning; nu is too big ** \n')
    end
end

sx1 = zeros(n,1); num1 = 0;
sKu = zeros(n,1); Knum1 = 0;
for i = 1:p
    if lambnz(i) > 0
        sx1 = sx1 + u(:,i);
        num1 = num1 + 1;
    end
    if lamK(i) > 0
        sKu = sKu + u(:,i);
        Knum1 = Knum1 + 1;
    end
end
% Knum1
sx2 = zeros(n,1); num2 = 0;
sKv = zeros(n,1); Knum2 = 0;
for j = 1:q
    if munz(j) > 0
        sx2 = sx2 + v(:,j);
        num2 = num2 + 1;
    end
    if muK(j) > 0
        sKv = sKv + v(:,j);
        Knum2 = Knum2 + 1;
    end
end
% Knum2
```

```

fprintf(' sum(mu) = %.15f \n',sum(mu))

if (numsvl1 > 0 || numsvm1 > 0) && badnu == 0
    if eta < 10^(-9)
        fprintf('** Warning, eta too small or negative ** \n')
        eta = 0;
    end
    delta = eta/nw;
    fprintf('delta = %.15f \n',delta)
    tolxi = 10^(-10);
    % tols < lambda_i < K - tolh or K - tolh <= lambda_i and epsilon_i < tolxi
    [lamsv,psf,epsilon] = findsvl2(lamb,w,b,u,eta,K,tols,tolh,tolxi);
    % tols < mu_i < K - tolh or K - tolh <= mu_i and xi_i < tolxi
    [musv,qsf,xi] = findsvm2(mu,w,b,v,eta,K,tols,tolh,tolxi);
    fprintf('psf = %d ',psf)
    fprintf(' qsf = %d \n',qsf)
    fprintf('pf - psf = %d ',pf - psf)
    fprintf(' qf - qsf = %d \n',qf - qsf)

    % computes eta from the duality gap
    errterm = w'*(sKv - sKu) + (pf - qf)*b;
    Pterm = (1/K)*(lam'*P2*lam);
    denom = (p+q)*nu - pf - qf;
    fprintf('denom = %.15f \n',denom)
    if denom > 0
        eta1 = (errterm + Pterm)/denom;
        fprintf('eta1 = %.15f \n',eta1)
    end
end
end

```

The constraint matrix and the matrices defining the quadratic program are constructed by the function `buildSVMs2pb`.

```

function [A,c,X,Pa,q] = buildSVMs2pb(nu,u,v,K)
% builds the matrix of constraints A for
% soft margin nu-SVM s2'

```

```

% with the constraint
% \sum_{i = 1}^p + \sum_{j = 1}^q mu_j = K_m
% (without the variable gamma) and the right-hand side c
% u: vector of p blue points (each an n-dim vector)
% v: vector of q red points (each an n-dim vector)
% builds the matrix X = [-u_1 ... -u_p v1 .... v_q]
% and the matrix Pa as 2(p+q) matrix obtained
% by augmenting X'*X with zeros
% K is a scale factor (K = Ks)

p = size(u,2); q = size(v,2);
% Ks = 1/(p+q);
Ks = K; Km = (p+q)*K*nu;
A = [ones(1,p) -ones(1,q) zeros(1,p+q);
      ones(1,p) ones(1,q) zeros(1,p+q) ;
      eye(p) zeros(p,q) eye(p) zeros(p,q);
      zeros(q,p) eye(q) zeros(q,p) eye(q) ];
c = [0; Km; Ks*ones(p+q,1)];
X = [-u v];
XX = X'*X;
Pa = [XX zeros(p+q,p+q); zeros(p+q, 2*(p+q))];
q = zeros(2*(p+q),1);
end

```

The function `findpsv2` makes a vector of λ_i (and μ_j) corresponding to support vectors of type 1.

```

function [lamps, num] = findpsv2(lambda, K, tols, tolh)
%
% This function find the vector of
% lambda_i's such that 0 < lambda_i < K
% and the number of such lambda_i.
%
% tols = 10^(-11); % the smaller this is, the larger the number of
%                  % points on the margin
% tolh = 10^(-9); %
m = size(lambda,1); lamps = zeros(m,1);
num = 0;
for i = 1:m
    if lambda(i) > tols && lambda(i) < K - tolh
        lamps(i) = lambda(i);
        num = num + 1;
    end
end

```

```
end
end
```

The function `countumf2` finds those λ_i such that $\lambda_i = K$.

```
function [lamK,mf] = countumf2(lambda,K,tolh)
% Counts the number of margin failures, that is,
% points  $u_i$  (in  $u$ ) such that  $\lambda_i = K$ 

p = size(lambda,1);
mf = 0; lamK = zeros(p,1);
for i = 1:p
    if lambda(i) >= K - tolh
        mf = mf + 1;
        lamK(i) = lambda(i);
    end
end
end
```

Similarly, the function `countvmf2` finds those μ_j such that $\mu_j = K$.

The function `countmlu2` finds those λ_i such that $\lambda_i > 0$.

```
function [lambnz, mlu] = countmlu2(lambda,tols)
% Counts the number of points  $u_i$  (in  $u$ )
% such that  $\lambda_i > 0$  and returns a vector
% of these  $\lambda_i$ 

% tols = 10^(-11);
p = size(lambda,1); lambnz = zeros(p,1);
mlu = 0;
for i = 1:p
    if lambda(i) > tols
        mlu = mlu + 1;
        lambnz(i) = lambda(i);
    end
end
end
```

Similarly, the function `countmlv2` finds those μ_j such that $\mu_j > 0$. The function `findsvl2` finds the λ_i corresponding to blue support vectors of type 1 and 2 and the error vector ϵ . The number of blue errors is psf (the u_i for which $\epsilon_i > 0$). Similarly the function `findsvm2` finds the μ_j corresponding to red support vectors of type 1 and 2 and the error vector ξ . The number of red errors is qsf (the v_j for which $\xi_j > 0$).

The main function runSVMs2pbv3 calls doSVMs2pbv3 and displays the separating line (or plane) and the two margin lines (or planes).

```

function [lamb,mu,alpha,beta,lambnz,munz,w] = runSVMs2pbv3(nu,rho,u,v,K)
%
% Best version
% Uses the duality gap to compute eta
% In principle, needs a single support vector of type 1
%
% Runs soft margin nu-SVM version s2'
% with the constraint
% \sum_{i = 1}^p + \sum_{j = 1}^q mu_j = K_m
% (without the variable gamma)
%
% p green vectors u_1, ..., u_p in n x p array u
% q red   vectors v_1, ..., v_q in n x q array v
%
% First builds the matrices for the dual program
% K is a scale factor
%
p = size(u,2); q = size(v,2); n = size(u,1);

[lamb,mu,alpha,beta,lambnz,munz,numsvl1,numsvm1,badnu,w,nw,b,eta]
= doSVMs2pbv3(nu,rho,u,v,K);

if n == 2
    [ll,mm] = showdata(u,v);
    if (numsvl1 > 0 || numsvm1 > 0) && badnu == 0
        showSVMs2(w,b,eta,ll,mm,nw)
    end
else
    if n == 3
        showpointsSVM(u,v)
        if (numsvl1 > 0 || numsvm1 > 0) && badnu == 0
            offset = 10;
            C1 = [1 0 1]; % magenta
            plotplaneSVM(u,v,w,b,offset,C1)
            C2 = [0 0 1]; % blue
            plotplaneSVM(u,v,w,b+eta,offset,C2)
            C3 = [1,0,0]; % red
            plotplaneSVM(u,v,w,b-eta,offset,C3)
        end
        axis equal
    end
end

```

```

    view([-1 -1 1]);
    xlabel('X','fontsize',14); ylabel('Y','fontsize',14);
    zlabel('Z','fontsize',14);
    hold off
end
end
end

```

B.3 Soft Margin SVM (SVM_{S3})

The following Matlab programs implement the method described in Section 54.12. The main function doSVMs3b is given below.

```

function [lamb,mu,alpha,beta,lambnz,munz,lamK,muK,w,b,eta,nw,fail]
= doSVMs3b (nu,rho,u,v,K)
%
% Soft margin nu-SVM version s3
%
% Computes eta using the duality gap
% Needs a single support vector of type 1
%
% p green vectors u_1, ..., u_p in n x p array u
% q red   vectors v_1, ..., v_q in n x q array v
%
% First builds the matrices for the dual program
% K is a scale factor
%
p = size(u,2); q = size(v,2); n = size(u,1);
[A,c,X,P2,Pa,qa] = buildSVMs3b (nu,u,v,K);
%
% Runs quadratic solver
%
tolr = 10^(-10); tols = 10^(-10); iternum = 80000;
[x,U,ns,kk] = qsolve1(Pa, qa, A, c, rho, tolr, tols, iternum);
fprintf('nr = %d ',nr)
fprintf(' ns = %d ',ns)
fprintf(' kk = %d \n',kk)
noconv = 0;
if kk > iternum
    noconv = 1;
    fprintf('** qsolve did not converge. Problem not solvable ** \n')
end

```

```

lam = x(1:(p+q),1);
alpha = x((p+q+1):2*p+q,1);
beta = x(2*p+q+1:2*(p+q),1);
w = -X*lam;
nw = sqrt(w'*w); % norm of w
fprintf('nw = %d \n',nw)
lamb = x(1:p,1);
mu = x(p+1:p+q,1);
b = -(sum(lamb) - sum(mu));
fprintf('b = %.15f \n',b)
%

tol = 10^(-10); tolh = 10^(-9);
% tol < lambda_i < K - tol
[lamnz,numsv1] = findpsv2(lamb,K,tol,tolh);
% tol < mu_i < K - tol
[munz,numsvm1] = findpsv2(mu,K,tol,tolh);
fprintf('numsv1 = %d ',numsv1)
fprintf(' numsvm1 = %d \n',numsvm1)
% lambda_i >= K - tol
[lamK,pf] = countumf2(lamb,K,tolh); % number of blue margin failures
% mu_j >= K - tol
[muK,qf] = countvmf2(mu,K,tolh); % number of red margin failures
fprintf('pf = %d ',pf)

Pa = [P zeros(2*m,2*m); zeros(2*m, 4*m )];
qa = [y; -y; zeros(2*m,1)];
end
```

Appendix C

Zorn's Lemma; Some Applications

C.1 Statement of Zorn's Lemma

Zorn's lemma is a particularly useful form of the axiom of choice, especially for algebraic applications. Readers who want to learn more about Zorn's lemma and its applications to algebra should consult either Lang [109], Appendix 2, §2 (pp. 878-884) and Chapter III, §5 (pp. 139-140), or Artin [7], Appendix §1 (pp. 588-589). For the logical ramifications of Zorn's lemma and its equivalence with the axiom of choice, one should consult Schwartz [150], (Vol. 1), Chapter I, §6, or a text on set theory such as Enderton [56], Suppes [173], or Kuratowski and Mostowski [108].

Given a set, S , a *partial order*, \leq , on S is a binary relation on S (i.e., $\leq \subseteq S \times S$) which is

- (1) *reflexive*, i.e., $x \leq x$, for all $x \in S$,
- (2) *transitive*, i.e, if $x \leq y$ and $y \leq z$, then $x \leq z$, for all $x, y, z \in S$, and
- (3) *antisymmetric*, i.e, if $x \leq y$ and $y \leq x$, then $x = y$, for all $x, y \in S$.

A pair (S, \leq) , where \leq is a partial order on S , is called a *partially ordered set* or *poset*. Given a poset, (S, \leq) , a subset, C , of S is *totally ordered* or a *chain* if for every pair of elements $x, y \in C$, either $x \leq y$ or $y \leq x$. The empty set is trivially a chain. A subset, P , (empty or not) of S is *bounded* if there is some $b \in S$ so that $x \leq b$ for all $x \in P$. Observe that the empty subset of S is bounded if and only if S is nonempty. A *maximal element* of P is an element, $m \in P$, so that $m \leq x$ implies that $m = x$, for all $x \in P$. Zorn's lemma can be stated as follows:

Lemma C.1. *Given a partially ordered set, (S, \leq) , if every chain is bounded, then S has a maximal element.*

Proof. See any of Schwartz [150], Enderton [56], Suppes [173], or Kuratowski and Mostowski [108]. \square

Remark: As we noted, the hypothesis of Zorn's lemma implies that S is nonempty (since the empty set must be bounded). A partially ordered set such that every chain is bounded is sometimes called *inductive*.

We now give some applications of Zorn's lemma.

C.2 Proof of the Existence of a Basis in a Vector Space

Using Zorn's lemma, we can prove that Theorem 3.7 holds for arbitrary vector spaces, and not just for finitely generated vector spaces, as promised in Chapter 3.

Theorem C.2. *Given any family, $S = (u_i)_{i \in I}$, generating a vector space E and any linearly independent subfamily, $L = (u_j)_{j \in J}$, of S (where $J \subseteq I$), there is a basis, B , of E such that $L \subseteq B \subseteq S$.*

Proof. Consider the set \mathcal{L} of linearly independent families, B , such that $L \subseteq B \subseteq S$. Since $L \in \mathcal{L}$, this set is nonempty. We claim that \mathcal{L} is inductive. Consider any chain, $(B_l)_{l \in \Lambda}$, of linearly independent families B_l in \mathcal{L} , and look at $B = \bigcup_{l \in \Lambda} B_l$. The family B is of the form $B = (v_h)_{h \in H}$, for some index set H , and it must be linearly independent. Indeed, if this was not true, there would be some family $(\lambda_h)_{h \in H}$ of scalars, of finite support, so that

$$\sum_{h \in H} \lambda_h v_h = 0,$$

where not all λ_h are zero. Since $B = \bigcup_{l \in \Lambda} B_l$ and only finitely many λ_h are nonzero, there is a finite subset, F , of Λ , so that $v_h \in B_{f_h}$ iff $\lambda_h \neq 0$. But $(B_l)_{l \in \Lambda}$ is a chain, and if we let $f = \max\{f_h \mid f_h \in F\}$, then $v_h \in B_f$, for all v_h for which $\lambda_h \neq 0$. Thus,

$$\sum_{h \in H} \lambda_h v_h = 0$$

would be a nontrivial linear dependency among vectors from B_f , a contradiction. Therefore, $B \in \mathcal{L}$, and since B is obviously an upper bound for the B_l 's, we have proved that \mathcal{L} is inductive. By Zorn's lemma (Lemma C.1), the set \mathcal{L} has some maximal element, say $B = (u_h)_{h \in H}$. The rest of the proof is the same as in the proof of Theorem 3.7, but we repeat it for the reader's convenience. We claim that B generates E . Indeed, if B does not generate E , then there is some $u_p \in S$ that is not a linear combination of vectors in B (since S generates E), with $p \notin H$. Then, by Lemma 3.6, the family $B' = (u_h)_{h \in H \cup \{p\}}$ is linearly independent, and since $L \subseteq B \subset B' \subseteq S$, this contradicts the maximality of B . Thus, B is a basis of E such that $L \subseteq B \subseteq S$. \square

Another important application of Zorn's lemma is the existence of maximal ideals.

C.3 Existence of Maximal Ideals Containing a Given Proper Ideal

Let A be a commutative ring with identity element. Recall that an ideal \mathfrak{A} in A is a *proper ideal* if $\mathfrak{A} \neq A$. The following theorem holds:

Theorem C.3. *Given any proper ideal, $\mathfrak{A} \subseteq A$, there is a maximal ideal, \mathfrak{B} , containing \mathfrak{A} .*

Proof. Let \mathcal{I} be the set of all proper ideals, \mathfrak{B} , in A that contain \mathfrak{A} . The set \mathcal{I} is nonempty, since $\mathfrak{A} \in \mathcal{I}$. We claim that \mathcal{I} is inductive. Consider any chain $(\mathfrak{A}_i)_{i \in I}$ of ideals \mathfrak{A}_i in A . One can easily check that $\mathfrak{B} = \bigcup_{i \in I} \mathfrak{A}_i$ is an ideal. Furthermore, \mathfrak{B} is a proper ideal, since otherwise, the identity element 1 would belong to $\mathfrak{B} = A$, and so, we would have $1 \in \mathfrak{A}_i$ for some i , which would imply $\mathfrak{A}_i = A$, a contradiction. Also, \mathfrak{B} is obviously an upper bound for all the \mathfrak{A}_i 's. By Zorn's lemma (Lemma C.1), the set \mathcal{I} has a maximal element, say \mathfrak{B} , and \mathfrak{B} is a maximal ideal containing \mathfrak{A} . \square
